The Canadian Engineer

A weekly paper for engineers and engineering-contractors

POWER DEVELOPMENT AT CEDARS RAPIDS, QUEBEC

THE PROGRESS THAT HAS BEEN MADE ON THE CONSTRUCTION OF CANADA'S SECOND LARGEST HYDRO-ELECTRIC DEVELOPMENT—DESCRIPTION OF THE PLANT

HYDRO-ELECTRIC development in the Montreal district has made rapid strides of late, and is on a scale that anticipates a great demand for power in the near future. Among the various activities, construction work has been progressing favorably since spring upon the hydro-electric power station of the Cedars Rapids Manufacturing and Power Co., near Montreal, Que. It is stated that when completed it will be the largest in Canada, with the exception of the Ontario Power Company's development at Niagara Falls.

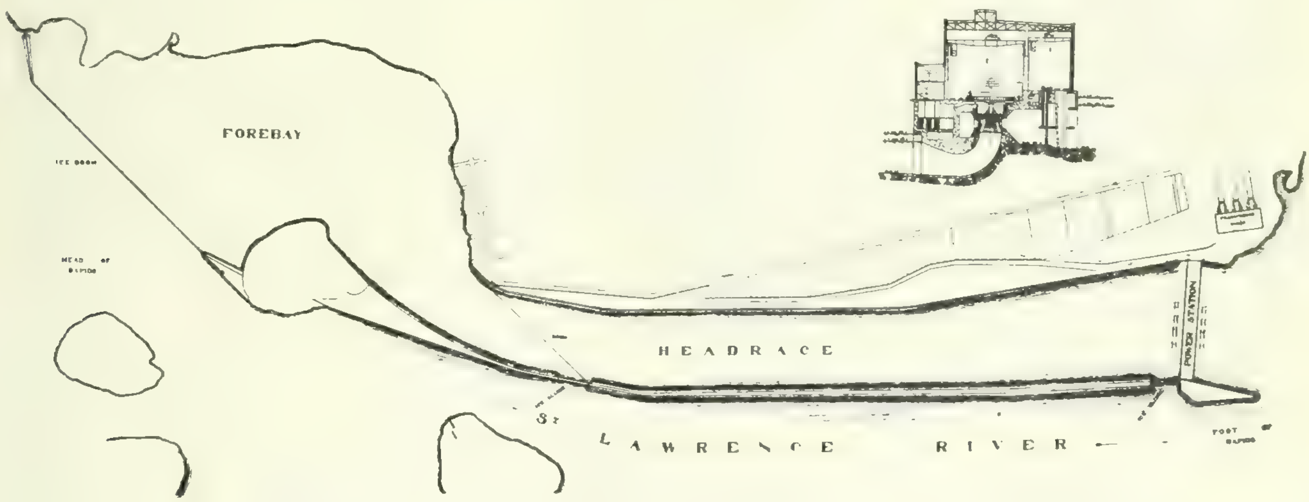

Fig. 1.—General Arrangement of Plant, and Cross Section of Power House.

About fifty miles above Montreal the St. Lawrence River widens out into Lake St. Francis. Above this lake there is a long series of rapids, known principally by the name of the longest one, the Long Sault. Lake St. Louis lies below Lake St. Francis, nearer Montreal, and between these two lakes the river falls through a distance of about eighty feet, made up chiefly of three rapids, namely, Coteau, The Cedars and the Cascade. The Cedars Rapids have a fall of 32 feet, and are located about 30 miles west of Montreal. At this point, the above company is constructing its power station to have an initial rating of about 100,000 h.p., and later to be increased to 160,000 h.p. The general arrangement of the development, showing forebay, headrace and power site, is illustrated in Fig. 1.

A brief summary of surrounding conditions on the St. Lawrence may be of interest. The Department of Railways and Canals, of the Dominion Government, maintains canals on both sides of the river for navigation past these three rapids. That on the south is the Beauharnois Canal, and that on the north, the Soulanges Canal. The former has been practically abandoned for navigation purposes, all traffic from the the Great Lakes to the Atlantic passing through the Soulanges.

The standing of the St. Lawrence River among the other great rivers of the world is well known. It drains a territory of over 300,000 square miles, a large percentage of which is lake area. Its steadiness of flow renders it distinctive among the largest rivers, the ratio of the maximum and minimum over a yearly period of time has not been known to exceed 3 to 1. Comparing this with the flow, for instance, of the Mississippi, which has a range of 25 to 1, or with the Susquehanna, which has a range of 75 to 1, the remarkable uniformity of the St. Lawrence River flow becomes a factor of inestimable value to any water power development.

For many years the development of the rapids in the St. Lawrence has been discussed, and numerous plans have been made, based upon different types of installation. According to the waterways treaty existing between Great Britain and the United States, which established the International Waterways Commission, any water power developments made on the St. Lawrence are subject to the approval of that commission. No diversions of the water from the river are permitted without careful investigation by that body, so as to insure that the levels for navigation purposes are not affected. In this connection it is to be stated that the commission, and the Dominion Govern-

ment as well, placed their marks of approval upon the proposed plan of works. The company may use 56,000 feet per second, sufficient to develop 160,000 electrical horse-power.

Headrace Construction.—The rapids at Cedars extend over a distance of about two miles. To concentrate this fall, a canal is being constructed along the north bank of the river, as shown in Fig. 1. The southern wall of the canal is built up from the rock excavated from the canal section, and is made watertight on the canal face by clay filling. This combination rock-fill earth bank requires special precautions against leakage or possible damage, the factors of safety being necessarily large. The type of construction, which is quite common in the case of large water reservoirs was considered to be the most economical, as all the materials were available at the site, and as the maximum head against the bank would never exceed 32 feet.

The water will be taken in above the Cedars Rapids between the Isle-aux-Vaches, forming the upper end of the dam, and the main shore. From this island to the power house there will be a length of canal of about 12,000 feet, forming a dam which concentrates about 32 feet of the fall. Fig. 2 is a view taken from Isle-aux-Vaches looking toward what will ultimately be the mouth of the canal. It shows the cableway used for the construction of the dyke extending the full length to the power house. The upper end of this earth bank, about 2,000 feet in length, is being constructed across a bay of the river and the material is being dumped from the cableway. The thin earth bank shown on the left is being retained at the present time to act as a cofferdam so that the main canal excavation may be carried on with steam shovels in dry ground.

The width of the canal on the water line will be about 1,000 feet. When finished its outer or south bank will be practically a straight earth wall two miles long and parallel thereto the shore forms a similar bank located on the natural flow of the river.

Ice Fenders.—The type of ice fender to be constructed at the upper end of the canal to divert floating ice from Lake St. Francis will consist of a number of submerged openings permitting the entrance of water into the canal at five or six feet below the surface. As this ice fender has the same general direction as the main current of the river, the ice which strikes the fender will be carried along by the heavy current and its own momentum, without entering the canal or impeding the entering flow. The usual precautions will be taken with respect to frazil ice, although in plants with these larger units a considerable amount may pass through the wheels without fear of causing interruption.

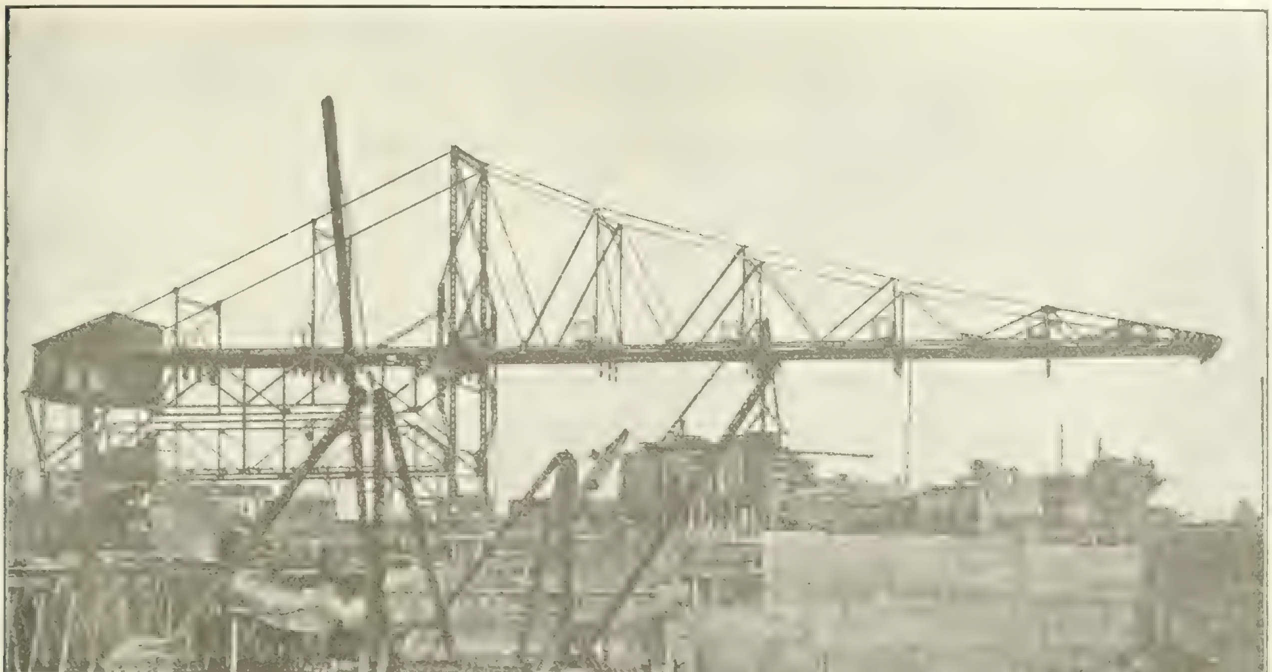
Power House Construction.—The power house will extend across the lower end of the canal forming a portion of the dam, giving, as stated, a fall of 32 feet. The building is 663 feet long, 140 feet in width, and from the rock to the top of the foundations is about 50 feet. The power house itself is being built of concrete, both foundation work and superstructure. The concrete work, at the present time, is finished to proper grade and the erection of the steel framework and superstructure is now being proceeded with. Fig. 3 illustrates the progress that has been made, three of the ten main units being completed and the others in a partial state. The method of construction of the draft tube for one of the main units is shown in the foreground. The illustration also shows to advantage the movable cantilever frame for the distribution of concrete. At this date work is in progress on the erection of the reinforced concrete units which are to form the power house superstructure. During the winter, and as rapidly as the foundation work will permit, steel will be assembled and these slabs put into place, so that waterwheel installation can go forward without delay.

Fig. 2.—South Bank of Canal Under Construction, View from Isle-aux-Vaches.

Power Plant.—The great improvements that have taken place during the past few years in the design of low head water turbines and single-runner wheels at reasonable speeds to develop large amounts of power is being taken advantage of to a marked degree, although the policy has not been to endeavor to obtain the largest available units. The generating equipment includes twelve 10,800-h.p. waterwheels of the single-runner vertical-shaft type, which are to operate at 56 r.p.m. under a head of 30 feet. There will also be three 1,500-h.p. exciter units which will operate under the same head at 150 r.p.m. The plans for the final development call for eighteen 10,000-h.p. units. The size of each unit is stated to have been chosen more with a view to economic operation and confidence in its reliability than with the endeavor to save a small amount by greatly increasing the size.

The intakes are of the scroll or involute type. The water passes through the racks at the up-stream face of the power house into the reinforced concrete flume, thus entering the wheel, and discharging through a centre draft-tube into the tailrace and the river. The wheel chambers are of spiral shape, formed in the concrete foundations of the building. The generator for each wheel is to be located immediately above. The weight of the moving parts will be carried on a thrust-bearing located above the generator, readily accessible for inspection and maintenance, and easily reached with a crane

Another feature is that the overall length of the generator and wheel is thus reduced to a minimum, and necessitates only two guide-bearings for the vertical shaft.



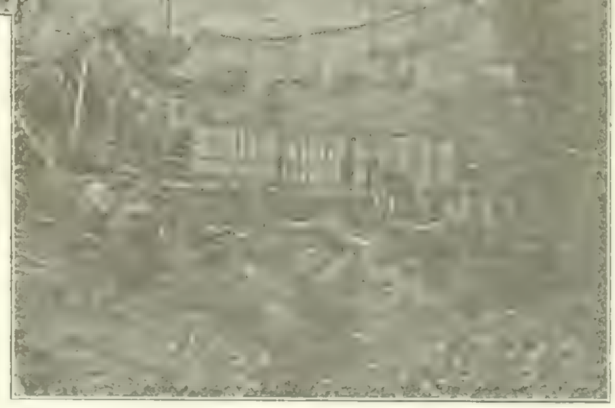


Fig. 3.—Power House Substructure, Showing One Draft Tube Under Construction.

In the design of the plant, an effort has been made to place on the main floor all the equipment that is vital to the continuity of its operation. This dispenses with an unfavorable feature of many vertical water power developments, in which the governor and thrust-bearing pumps and other auxiliary machinery are located below the generator floor, where they are not readily accessible for repair or close supervision, although ample floor space above is thus obtained.

Fig. 4.—Placing of Column Footings, Transformer Station.

The transformer house is to be constructed to take care of 100,000 h.p. initially. The building is quite separate from the power house, and is located on a higher elevation about 300 feet distant. Fig. 4 shows the commencement of work on the transformer house, and illustrates the excavation and placing of the footings for the columns and walls of the building.

Progress.—It is anticipated that the plant will be ready for the deliverence of 100,000 h.p. in October, 1914. The progress that has been made up to date is as follows:—

	Per cent. completed.
Rock excavation	23.2
Earth excavation, other than stripping and trench work	60.0
Earth excavation, in trenches and ditches, and stripping seats of banks	84.0
Transporting and placing of excavated rock	27.7
Stone protection	2.7
Transporting and placing of excavated earth	62.5
Concreting of power house substructure	25.5

The work constitutes the removal of about 700,000 cu. yds. of rock, and 1,600,000 cu. yds. of earth excavation. There will be a total of 80,000 cu. yds. of concreting.

Personnel.—The Cedars Rapids Manufacturing and Power Company was organized with ample powers for the development of water power at Cedars Rapids, and for the construction of transmission lines. The lands

were acquired, and, as stated, the approval was obtained of the International Waterways Commission and of the Dominion Government. As a result of its magnitude, however, and of the fact that the greater portion of the development would necessarily have to be made before any power could be obtained, this power stood idle until the control became vested in the joint interests of the Shawinigan Water and Power Co., and the Montreal Light, Heat and Power Company. Soon after this transfer of control contracts were made with the Aluminium Company of America to take 60,000 h.p. and with the Montreal Light, Heat and Power Company to take 20,000 h.p. These contracts practically insured the success of the venture from a financial standpoint, and work was immediately commenced. The president of the company is Mr. J. E. Aldred; its hydraulic engineer is Mr. J. C. Smith, and its electrical engineer, Mr. R. M. Wilson.

The turbine units are being constructed by the I. P. Morris Company, of Philadelphia, and the Wellman-Seaver-Morgan Company, of Cleveland. The first three turbine units have already been delivered. Three electrical generators are also on the ground, being supplied by the General Electric Company of Connecticut. The work of installation will be commenced about January 1st, 1914.

THE POWER PROBLEM IN THE ELECTROLYTIC DISPOSITION OF METALS.

A joint meeting will be held on January 9th, 1914, in the Engineering Societies Building, 29 West 39th Street, New York, by the American Society of Mechanical Engineers, the American Institute of Electrical Engineers and the American Electrochemical Society, to discuss the above problem. The following illustrated papers will be presented:—

The Limitations of the Problem, Lawrence Addicks, A.E.S. A brief statement of the conditions imposed by practice in the electrolytic refining of copper as a typical process.

The Mechanical Side of the Problem, H. E. Longwell, A.S.M.E. Application of gas and steam for driving generators of the type required.

The Electrical Side of the Problem, F. D. Newbury, A.I.E.E. Application of various D.C. and A.C.-D.C. apparatus to furnish current of the required dimensions.

As the subject is a much broader one than the typical case chosen for the formal papers, an interesting discussion is expected.

A report of the United States Bureau of Mines, which deals with fatalities in the metal mines of the country for 1912, shows that Michigan has reduced its total of deaths in the copper and iron mines from 134 in 1911 to 96 in 1912; and that Minnesota has reduced its total deaths in the iron mines from 76 to 50 in the same period. The death rate for every 1,000 men employed in Michigan was 4.24 in 1911 and 3.26 in 1912; and in Minnesota 4.59 in 1911 and 3.02 in 1912. The Bureau's report on metal-mine accidents in the United States in 1912, shows 661 men killed, 4,502 seriously injured and 26,232 men slightly injured, out of a total number of 169,199 men employed. The figures show a decrease of 34 deaths from 1911, despite the fact that Alaska, with 21 fatalities is included for the first time in the 1912 report. The death rate for 1912 was 3.91 for every 1,000 men employed as against 4.19 in the year 1911. The report completes the mortality statistics for the mining industry for the year 1912 and shows in coal mining, metal mining and quarrying, a total of 3,234 deaths for the year, with a death rate of 3.22 as against 3,602 deaths in 1911 and a rate of 3.58 in every 1,000 employed.

PRACTICABLE MEASURES FOR CIVIC BEAUTIFICATION.

An article by Fred L. Macpherson, municipal engineer, Burnaby, B.C., in December 18th issue of *The Canadian Engineer* outlined the place of tree-planting in civic beautification, and presented a weighty argument in favor of more trees and more boulevards in towns and cities, emphasizing the necessity of combining the efforts of the municipal engineer and the landscape architect for efficient results. The following information respecting the same subject, in conjunction with the article referred to, formed a paper presented to the Burnaby Board of Trade last month:

Boulevarding.—This feature of street beautifying does not require so much skill and experience as tree-planting, and if the boulevards are previously rough-graded and curb constructed by the corporation, it should be a simple and easy matter for the property owner to undertake the fine grading, supply any necessary top soil, and sow the seed. The chief essentials of a good boulevard are good top soil, efficient drainage, evenness, uniformity and spaciousness. After the boulevard has been rough-graded it is advisable to loosen the soil with a mattock to a depth of from 8 to 10 inches in order to get rid of the surplus stones and afford better drainage. In very wet places tile or stone drains should be put in. In unpaved streets or in the absence of stone curbs, wooden curbs should be constructed to define the limits of the travelled road-bed, to retain the earth in the boulevard and to prevent it from being damaged by vehicular traffic. Where a curbing system is not adopted the boulevard is likely to have a ragged and incomplete appearance, and to be injured by traffic. In cases where the boulevard is not intended to be regularly mown only white Dutch clover, at a rate of about 1 pound for every 300 square feet should be sown, but where permanent boulevards are desired the use of lawn seed with a small percentage of white clover will produce a fine, velvety turf.

Where the property is a few feet above the level of the roadway very pretty effects can be obtained by planting broadleaf ivy on the slopes down to the sidewalk. On very broad boulevards two rows of trees are often planted, and sometimes evergreen shrubs are planted alternately with the trees either on the parking strip between the sidewalk and the curb or next the property line.

As regards fences and hedges, this is a matter for individual taste. Hedges, particularly evergreens, play an important part in a boulevarding scheme, but ordinary fences, particularly high fences, usually tend to mar the finished appearance of the boulevard. While fences are permissible for proper protection from the ravages of dogs, the prettiest and fullest effects are produced when the lawns fronting residences are an integral portion of the street boulevard. For the purpose of defining the property line a low concrete wall or curb about 9 inches high might be used without taking away from the spacious appearance of the boulevard. On our rural highway hedges of beech, hawthorn and privet such as are in adoption in the homeland could be introduced with advantage to the beauty of the rural landscape.

The use of rose bushes as a streetscape feature is worthy of commendable mention. Portland has earned world-wide name and fame as the "Rose City" and set a rosy example for other cities and districts to imitate if not to emulate. Here is a striking instance of what can

be done by public-spirited and civic-inspired citizens to give beauty and life and character to a city. While roses would not bloom so early in this district, the soil is suited for their culture and there is no reason why the rose boulevard system should not be introduced with happy effect in the more strictly residential districts hereabouts.

A highly important feature more or less directly associated with any boulevard beautifying scheme is the fixing of the building line. It is a matter for common regret and sometimes, civic reproach, that property owners are permitted to build as far away from or as close to the property line as their individual taste or desire elects. In few cities or districts there appears to be any restrictions as to the limit at which houses, particularly on residential streets, may be built, from the property line or the distance at which they may be built from adjacent houses. Apart from the sanitary drawbacks and the fire hazards resulting therefrom, the irregular and unsymmetrical effects produced are detrimental to the most happily conceived street beautifying scheme. Strict attention to or gross neglect of this vital matter will make or mar the realization of any boulevarding system. A building limit should be prescribed in any model building by-law, and rigidly enforced.

Cost.—As regards the cost of tree planting and boulevarding, conditions and circumstances vary so much as to render cost data unreliable. Trees cost from 50 cents to $1.50 each, depending on the age and species, and whether they are reared in private or corporation nurseries. The cost of tree-planting will range from 30 cents per tree to as much as $2 where hardpan has to be removed and prepared soil furnished. Providing protection guards would be additional to the above costs. The cost of preparing roughly graded boulevards, and soiling and sowing will average about 40 cents per square yard. As for the cost of maintaining boulevards, reliable records do not appear to be available, but 5 cents per foot front or about 6 cents per square yard is a customary allowance for yearly maintenance.

From the accompanying statement of comparative data procured from different places in Canada and the United States—and it is remarkable how very little reliable data is available—will be gleaned some interesting information regarding the question of boulevarding and tree-planting.

Public Squares and Play Grounds.—A passing reference to the part which public play grounds and squares play in any civic beautifying scheme may not be out of place. A glance at the map of Burnaby is sufficient to impress one with feelings of disappointment and resentment that little or no provision has been made for public squares and play grounds. This is only one of many regrettable instances in which the exploitation of real estate interests for pecuniary gain has predominated in the subdivision of property regardless of public interests and prospective civic requirements. In the sane and economic development of property sufficient space should be reserved by property owners in the central portion of almost every district lot, for public squares and play grounds. It is remarkable as it is regrettable that in this country there are comparatively few wealthy citizens—usually made wealthy through the sale of land—sufficiently magnaminous and public-spirited to bequeath such public benefactions as sites for public squares. Meantime, the provincial adoption of a Town-planning Act similar to that which has been in beneficial operation in Britain since 1909, would prevent, or at least restrict, the present merciless land exploitation and insure the planning and development of any city or district along sane, healthy and intelligent lines.

As regards the beautifying of school play-grounds, many authorities have given little or no consideration and care towards making them more adaptable and attractive for what they were primarily intended—namely, playing grounds. The seeding of the grounds and the judicious planting of ornamental trees and shrubs—which could be accomplished at comparatively small cost—would serve the edifying purpose of inspiring in children the love for and reverence towards Nature, besides providing for healthful recreation for the young. Now that our streets are rendered more dangerous through increasing automobile traffic suitable and easily accessible playing grounds are an imperative necessity for the free use of children.

Control of Shade Trees, Etc.—The all-important question of the control of and the regulation of the planting and preservation of shade trees and the maintenance of boulevards, is one which deserves the widest and maturest consideration, to the end that the best interests of public corporations as well as private citizens be duly respected and conserved. As things are at present in nearly all our cities and districts such matters are left almost wholly to the care and caprice of property owners with what incomplete and unsatisfactory results is all too apparent. Frequently on one street there are three or four kinds of trees, desirable mixed with undesirable, all sizes and shapes, and varieties, planted too close or too far apart, untended and untrimmed. The results are obvious. While the enterprising and well-meaning efforts and achievements of property owners should not be discouraged or discounted, the fact remains that it is only when the rights and privileges of undertaking such beautifying work are vested under one authority and under the proper supervision of an efficient department that entirely successful and satisfactory results can be ultimately produced. In most cities such matters are entrusted to the dual, care and control of both the engineering department and the park board, invariably with indefinite and imperfect results—a case of anybody's business being nobody's business. Being distinct from ordinary street work, such matters would be better left entirely in the hands of a capable park board, or in the absence of such, a properly constituted boulevard and shade tree commission. This also forcibly applies to maintenance, for when planted shade trees become a public asset and therefore should not be left to the care and custody of the average inexperienced and indifferent property owner. On the other hand, it might be justifiably argued that giving such boards or commissions absolute authority in such matters would be derogatory to private interests and rights and might even permit of vandalism. The ruthless mutilation of street trees to accommodate companies operating telephone or light and power systems with the property owners powerless to object or prevent might create an undesirable state of affairs. According to the Ontario Tree Planting Act, trees left or planted on public highways become the property of the adjacent property owners. Neither municipal authorities nor property owners can, in that province, legally remove or interfere with street trees without the will and consent of the other interested party. Such a regulation has much to commend it, for without such protection property owners would have no insentive to plant trees on their own initiative. Generally speaking, however, one properly organized and competent body should have the

power to direct and regulate the planting and preservation of street trees and the construction and maintenance of boulevards. With the growth of the boulevard movement it is being more and more generally recognized that such a system is more efficient and economical in the long run. Such work being particularly of a private nature, the cost should reasonably be assessed on the property owners directly benefited thereby, although in some instances the corporation might justifiably contribute a small proportion of the annual cost of maintenance. Most corporations pass by-laws to validate such beautifying schemes but it is one thing to enact and quite another to cause to act. The movement is deserving of more encouragement and greater support than it usually receives from municipal authorities, whose progressive actions would undoubtedly be acceded to by an appreciative public.

COMPARATIVE DATA ON BOULEVARDING AND TREE-PLANTING.

City or town.	Mode of carrying out work.	Cost of tree-planting each per tree.	Cost of boulevarding per lin.ft.	Cost of maintenance per sq. yd.	Distance of feet apart.	Distance from property line.	Remarks.
Seattle	Private enterprise	No information	No information	No information	—	—	Not under jurisdiction of any city department
Edmonton	Local improvement	$1.75 (including protection)	$1.80 to $2.75	4 cents	10 ft.	15 ft.	Not under jurisdiction of any city department
Portland	Local improvement and revenue	$1.05 to $5.00	35c. to 95c. per sq. yd.	No information	40 ft.	9 ft.	Not under jurisdiction of any city department
Nelson	Private enterprise	90c.	No information	No information	20 ft.	12½ ft.	Not under jurisdiction of any city department
Minneapolis	Local improvement assessed over a term of 3 years	$6.00	—	No maintenance done by city	40 ft.		Boulevards roughly graded by works dept.
Calgary	Local improvement	75c.	40c. per sq. yd.	No record kept	12 ft.	11 ft.	Trees grown in own nurseries
Chicago	Private enterprise and park commission	$5.00	$1.30 per sq. yd.	No record kept	12 to 50 ft. according to variety		
New Westminster	Local improvement	—	35 cents	No record kept	Varied	Varied	
Kamloops	Revenue account	$1.00	40 cents	No record kept	10 ft.	—	Work not organized
Victoria	Local improvement	$1.00	—	—	30 ft.	Varied	

PRESERVATIVES PROLONG LIFE OF POOREST WOODS.

As a result of the many inquiries in regard to the preservative treatment of fence-posts, the Forestry Branch, Ottawa, has now issued a circular on this subject which can be had by applying to the Director of Forestry. The various methods described of treating the posts with the preservatives are all illustrated by diagrams, and the apparatus required is simple and costs little.

The great advantage of these treatments is that they keep even cheap woods free from decay for from 10 to 15 years. Many kinds of wood found in wood lots will last, when used as posts, only four years or thereabouts; after treatment, such as described, they last twice or three times, even four times, as long.

Creosote, which costs in Canada, from 10 to 25 cents a gallon, is the best preservative. When boiling-hot creosote is applied with a brush—a paint brush or whitewash brush, for instance—to the butts of well-seasoned posts from which the bark has been removed, it sinks into the wood for a distance of about a quarter of an inch. This should add at least 10 years to the life of a post made from a non-durable wood, such as poplar, balsam, fir or spruce. This is not the best method, but it is the simplest and, on a small scale, probably the cheapest. Other methods require that the posts be kept covered in tanks of hot creosote for a longer or shorter period.

Besides lengthening the life of the post, the preservative treatment also tends to reduce the cost of the posts in another way, for, as cheap local woods can be used, the first cost and the cost of transportation are usually much lower than for cedar, oak or tamarack. Moreover, as posts will need to be set less often, the proportionate cost of setting the post will be less. Taking into account all the items that go to make up the cost of the post, and comparing this with the number of years it will last, it will be found in the majority of cases, to be much less for treated posts.

FINISHED STEEL PRODUCED IN CANADA IN 1912.

THE figures collected by the Statistical Bureau of the American Iron and Steel Association show that the total production of steel in Canada in 1912 was 853,031 long tons; 207,569 tons being bessemer, 645,062 openhearth and 400 tons special steel. The openhearth steel was all basic. The production included 4,238 tons of direct castings from bessemer steel and 28,001 tons from openhearth steel. By provinces, Nova Scotia produced 416,313 tons and Ontario 417,634 tons, the remaining 19,084 tons being made in Quebec and British Columbia.

The production of steel ingots—including direct castings—in Canada has been as follows for nine years in long tons:—

	—Bessemer—		—Openhearth—		Total
	Tons.	Per cent.	Tons.	Per cent.	tons.
1904. . . .	42,738	28.7	106,046	71.3	148,784
1905. . . .	164,488	40.8	238,681	59.2	403,449
1906. . . .	219,791	38.5	347,778	60.1	570,889
1907. . . .	202,268	31.3	440,936	68.2	646,754
1908. . . .	108,433	21.3	401,119	78.7	509,957
1909. . . .	182,304	27.0	496,142	73.0	678,751
1910. . . .	199,570	27.0	542,354	73.0	741,924
1911. . . .	189,797	24.0	601,074	76.0	790,871
1912. . . .	207,569	24.4	645,062	75.6	853,031

The small production of special steels is included in the totals. In most of the years given it was only a few hundred tons, except that in 1906 and 1907 it reached 3,320 and 3,550 tons, owing to the inclusion of some experimental work.

Finished Iron and Steel.—The production of all kinds of finished rolled material in Canada in 1912 was 861,224 tons, 109,012 tons being iron and 752,212 tons steel. The total was greater than that for 1911 by 79,300 tons, or 10.1%. Of the total, rails were 423,885 tons; structural steel and wire rods, 64,082; plates, sheets, bars and other forms, 373,357 tons. Ontario produced 418,346 tons, Nova Scotia, 337,466; Quebec, 88,172, the remaining 17,240 tons being from New Brunswick, Alberta and Manitoba.

The production of rails and the total make of all kinds of finished iron and steel in Canada for 10 years has been:—

	Rails.	Total.
1903	1,243	120,516
1904	36,216	180,038
1905	178,885	385,826
1906	312,887	571,742
1907	311,491	600,179
1908	268,692	496,517
1909	344,830	662,741
1910	366,465	739,811
1911	360,547	781,924
1912	423,885	861,224

In 1912 there were 31 plants which made steel ingots or castings or rolled iron and steel into finished forms. Six of these were in Nova Scotia, eight in Quebec, 13 in Ontario, one each in New Brunswick, Manitoba, Alberta and British Columbia. Two new steel-casting plants were built during the year in Quebec and two in Ontario; at the close of the year a new merchant bar mill was under construction in Alberta.

Miscellaneous.—Other production of finished material in Canada in 1912 was as follows, compared with the previous year:—

	1911.	1912.	Changes.
Forgings, tons	18,832	22,415	I. 3,583
Rail joints	......	52,157	......
Nails, kegs of 100 lbs. ..	652,861	788,190	I. 135,329

The production of rail joints was not reported in 1911. Of the forgings made in 1912 there were 21,548 tons of steel and only 867 tons of iron. All the nails made were of steel.

GAS WELLS AT MEDICINE HAT.

IN order to show exactly what has been done in Medicine Hat, Alta., in the way of drilling gas wells, the city engineer's office has furnished a statement of the number of wells operated or in construction, with the depth of same, name, open flow in cubic feet per 24 hours, year drilled and rock pressure in lbs. per square inch. This information is the first of the kind yet issued, and was prepared at the request of the Board of Trade, the data being as follows:—

No. of well.	Depth, feet.	Open flow, cu. ft., 24 hours.	Year drilled.
1	1,000	2,225,000	1904
2	1,000	3,000,000	1906
3	1,000	2,500,000	1909
4	1,000	2,500,000	1911
5	1,200	4,000,000	1911
6	1,000	2,000,000	1908
7	1,200	2,500,000	1911
8	1,300	3,000,000	1913
9	1,002	2,200,000	1913
10	1,100	2,800,000	1909
11	1,050	2,900,000	1910
12	1,202	2,300,000	1913
13	1,202	2,100,000	1913
14	1,075	3,300,000	1913
15	1,075	2,900,000	1913
16	1,033	2,500,000	1912

NOTE—In the case of each the rock pressure is given as 550 pounds.

In addition, drilling has been started on Well No. 17, and the Medicine Hat Brick Co. has a well 1,050 feet deep. For some years the Canadian Pacific Railway has had a gas well on its right-of-way near the station, and work has just been completed on a second well for the Canadian Pacific Railway, the depth, open flow and rock pressure averaging with the other natural gas wells in this city.

The above twenty wells are all in the city limits, and it is notable that there has been no appreciable diminution in the pressure or flow from the same, notwithstanding the increased consumption of natural gas, due to the rapid industrial expansion of Medicine Hat.

This list does not take into account the string of wells being drilled by the Hunt Engineering Co., for the $2,500,000 plant of the Canada Cement Co., which will also purchase its water supply from this municipality.

CONSTRUCTION AND MAINTENANCE OF ROADS WITH REFERENCE TO METHODS PRACTISED IN SCOTLAND.

By Robert C. Muir, C.E.

FOR convenience the subject is divided by the writer into paved roads and macadamized roads; and let it be stated at the outset the most important feature of both is the foundation. One may make the surface of the very best material procurable, but unless there is a good, sound and well-drained foundation it is of no avail.

Of the paved roads granite, or other stone setts and pitchers, wood blocks and asphalt will be dealt with.

The first cost of any paved road is comparatively heavy; therefore, before deciding whether to convert a macadamized road into a paved road the necessity of the case must be investigated. As a general principle, if a conversion is to be made, or if a new roadway is to be constructed, in a neighborhood where there is a very heavy traffic, but dwelling houses and stores do not abut, a granite or whin paving is used; otherwise wood or asphalt is used. If a macadamized surface has to be renewed as frequently as once in two years and to be patched intermittently, a stone paving will prove more economical. If traffic weight is to determine the point, 250 tons per yard width per day of sixteen hours may be taken as the limit for macadam. In laying down the two-year-old rule, town roads are particularly in view, where the cost of cleaning, watering, etc., has to be contended with to a greater degree.

At this stage it may be convenient to consider the life and cost of granite sett and wood paving. In England and Scotland the Local Government Board grant loans for the following periods:—

Granite Setts	20 years
Hardwood	10 "
Soft wood	7 "
Concrete foundations	20 "

Under average conditions of traffic, granite setts will wear for thirty years, if not more; wood paving would wear for at least fifteen years. There is still a good value in granite setts at the end of thirty years, and they can be lifted and redressed. The seven-year period for soft wood is perhaps rather short, and if one calculates the interest and annual instalment for repayment, and adds to them the cost of repairs—which becomes increasingly heavy as time goes on—it will be found that the financial operation is not a profitable one. The repairs may vary from 5 cents to 25 cents per square yard per annum. Maintenance contracts extending over twenty years, at 15 cents per square yard per annum, the paving to be left in good condition at the end of that time, are in force, and have been lately renewed in many towns.

Before commencing any reconstruction of roads due notice should be given to gas, water and other authorities having mains in the road, so that they may have the opportunity of relaying or examining the same; otherwise the new work may probably be pulled up for renewal, etc., of pipes soon after it is finished.

Stone Paving.—The foundation should consist of a bed of 6 to 7½ inches of Portland cement concrete (6 to 1), the depth varying to traffic weights and the depth of stone used. All recently filled-in trenches should be dug out to a depth of 6 inches below the ordinary formation level, and for a width of about 6 inches to 9 inches in each side of the trench, and splayed back to an angle of 45 degrees; and then filled in with concrete. If a wet or clayey ground be present there should be a sub-bed, tightly rolled, of 4 to 6 inches of fine furnace ashes, to keep the clay down and the concrete dry. There is nothing better than fine ashes to stifle clay.

The paving stone most to be desired is a hard and tough material that will resist wear, and at the same time not become polished by the traffic. In Scotland and England the Aberdeen and Enderby granites have given the best results.

A good size for pitchers is about 4 inches wide, 8 inches long and 6 inches deep, and for setts, 4-inch cubes or 4 by 4 by 5 inches deep, the stones to be carefully dressed and squared with no greater discrepancy in depth than ¼ inch.

The 4 by 4 by 5-inch setts are to be preferred, laid on a 1-inch sand bed in courses at an angle of 45 degrees, with the channel courses, which generally consist of 12 by 6-inch flat stones or three courses of setts, the setts grouted with Portland cement grout (2½ to 1). A pitch joint gives a slightly quieter paving, but the edges of the stones are more liable to be chipped off. Keep the traffic off the work until the concrete and jointing are set.

Wood Paving.—The same remarks as to foundation apply as in the previous case. The most usual depth of concrete is 7½ inches, with 1½ inches of Portland cement rendering (2½ to 1), finished with the steel trowel to a true and smooth surface, washed ¼-inch granite or whin chippings and sand being used, the rendering to be absolutely hard and dry before the blocks are laid.

Jarrah, karri and blackbutt, also English oak in "prismatic" form and creosoted, are hard woods which have given good results. In these woods the most useful size of block is 3 by 9 by 4 inches deep, and in creosoted deal 3 by 9 by 5 inches deep. Jarrah, karri and blackbutt should be laid with close joints and dipped one side and one end in a boiling mixture of pitch and creosote oil. There is no necessity to dip the "prismatic" oak blocks if creosoted, except the channel courses, the bituminous grout following down well between the joints. Creosoted deal blocks are generally laid with a slight joint, often kept open by laths 1 inch deep and 1/10 inch wide, laid at the bottom of the courses.

Adequate expansion joints are provided next to the curbs, but there is very little expansion or contraction in the "prismatic" oak paving, and not so much in the creosoted deal as in the jarrah, karri or blackbutt.

Round gravel for surface dressing the paving should not be used; it is driven into the blocks by the traffic and destroys the fibre.

Asphalt Paving.—Asphalt gives a good wearing surface; it is clean, healthy and durable; its great fault is slipperiness. The rock asphalt, laid in the form of powder on a concrete foundation is compressed with heated irons into a homogeneous mass. When laid 2¼ inches thick (compressed) it will last fifteen years under heavy city traffic. The cost is about $3.50 per square yard, including foundation. The cost of repairs, averaged over the whole life, is 12 cents per square yard per annum. The mastic asphalt, melted with a flux of pitch and about 20 per cent. of clean coarse grit added to give a foothold, and laid in a mastic state, is not so durable as the compressed powder, and is sooner acted on by the sun.

Macadamized Roads.—In country roads we are generally able to deal with the drainage of the foundation of

the surface by means of the side ditches, but in towns it is necessary to provide a sysem of sub-drainage and lead the water away by means of pipe drains. The surface water (as from the paved roads also) is dealt with by gullies connected to the sewers, the number of gullies depending on the gradients of the roads.

The roadway should be of the same strength all over; that is to say, in excavating (or filling in) for the foundation, from it to the contour of finished surface. When roads are curbed and channelled they should be laid on a bed of 6 inches of Portland cement concrete. A good foundation is a layer of clean ashes or broken stone 6 inches in depth; on this a second layer, consisting of hand-set stone (whin or freestone) 8 inches in depth set on edge in the manner of a rough pavement. Over this layer a coating of broken stone should be laid, so as to fill up the intersticies and form a smooth surface; each layer to be thoroughly consolidated by a 10-ton steam roller. No round gravel should be used; it will work its way up through the metalling when thin, and it is not at rest in the road when under heavy traffic.

The metalling for finishing the roadway should be of the very best quality obtainable, tough and hard, broken so as to be as cubical as possible, and so that every stone shall pass through a 2½-inch ring in any direction; the same to be spread in two coats.

The first coat having been uniformly spread over the whole roadway should be rolled by a 10-ton steam roller until consolidated; the second coat should then be uniformly applied and consolidated, and the whole surface receive a coating of fine chippings of the same stone as the metal. The chippings should be screened through a ¾-inch mesh and to include the fine material down to dust. The roadway should be well watered and rolled until thoroughly consolidated.

On completion it should present a hard and perfect surface, true in level and cross section, and coated with a thin layer of ½-inch chippings of similar material free from dust. The depth of metalling will vary according to traffic, but 6 inches is recommended for first-class roads.

Instead of water-binding method just described, the use of bituminous binder has recently been revived. The principle is to spread it about ¾-inch thick, lay the metal thereon, and squeeze the binder up between the stones by rolling. In heavy coating, the operation is performed in two applications. Good weather is necessary for the work, and it requires special care, the cost is little less than tarred macadam.

The results of the use of a bituminous binder are less wear and tear and less mud and dust, consequently a longer life.

The subject of tarred macadam is now receiving considerable attention. Its utility greatly depends on the ingredients, their treatment and mixing, concerning which space does not permit of writing, but which will be explained fully in a paper to be published later, in connection with the good roads movement in Canada. When it is said that this material will stand heavy traffic, what is meant by it? It is not expected to wear like stone or wood paving. If the comparison is with ordinary macadam, then the process of bituminous binding will not stand heavy traffic either. When tarred macadam is used, the writer is in favor of a bottom course of 4 inches of tarred 2-inch stone and a top layer of 1½ inches of fine, rather than finishing the surface with larger stones; I believe that this system is better for repairing purposes. A tandem roller is best for this work. The traffic should be kept off all classes of macadamized roads while they are being constructed, and until the surface has dried out.

Taking into consideration the items of utility and cost and the facilities of construction and repair, I am of opinion that of macadamized roads, one constructed with good stone (waterbound) on a proper foundation, and the surface properly coated with hot coal gas tar, is the best.

The system of tar spraying roads by machinery has facilitated and reduced in cost one of the greatest boons conferred upon the users of macadamized roads. It lessens wear and tear, prevents damage by suction of pneumatic tires, reduces dust to a minimum, reduces mud, and generally increases the life of a road.

Watering is unnecessary for maintenance on tarred surfaces, and when watering is resorted to on ordinary macadam the spray should be fine.

In repairing or patching ordinary macadamized roads, the surface of the defective place should be picked up, the old material removed, fresh stone laid and rolled in. The use of a little fine tarred stone will be found useful as a binder in dry weather.

In recoating, the old surface should be scarified not too deeply, the fine material and such of the old stone as is usuable removed, and the new stone be then applied.

Camber.—If the difference in level between the centre and side of a road were properly apportioned instead of making the middle too flat, there would not be so much complaint of excessive camber. The writer would suggest 1 in 25 for macadam, 1 in 36 for soft wood, and 1 in 45 for whin or granite setts, hard wood and asphalt paving.

INTERNATIONAL ELECTRICAL CONGRESS, SAN FRANCISCO, 1915.

The International Electrical Congress is to be held at San Francisco, September 13th to 18th, 1915, under the auspices of the American Institute of Electrical Engineers by authority of the International Electrotechnical Commission, and during the Panama-Pacific International Exposition. Dr. C. P. Steinmetz has accepted the honorary presidency of the Congress. The deliberations of the Congress will be divided among 12 sections which will deal exclusively with electricity and electrical practice. There will probably be about 250 papers. The first membership invitations will be issued in February or March, 1914

Attention is drawn to the distinction between this Electrical Congress and the International Engineering Congress which will be held at San Francisco during the week immediately following the Electrical Congress. The engineering congress is supported by the societies of Civil, Mechancial and Marine Engineers and by the Institutes of Mining and Electrical Engineers, as well as by prominent Pacific Coast engineers who are actively engaged in organizing it. This Congress will deal with engineering in a general sense, electrical subjects being limited to one of the 11 sections which will include about 12 papers, treating more particularly applications of electricity in engineering work.

The meeting of the International Electrotechnical Commission will be held during the week preceding that of the Electrical Congress.

THE PROGRESS OF CANADIAN PACIFIC RAILWAY IRRIGATION IN ALBERTA.

THE engineering features of the irrigation projects of the Canadian Pacific Railway in Southern Alberta were described in detail by Mr. A. S. Dawson, Chief Engineer, Department of Natural resources of that company, in July 18th and July 25th, 1912, issues of *The Canadian Engineer* (pp. 192-225). For a history of irrigation in the West dating from 1892, and for an outline of the developments of more recent years, particularly the above development in the Bow River Irrigation Block, containing 3,097,000 acres, the reader is referred to this article.

The block divides itself naturally by topography into three sections of approximately 1,000,000 acres each. The Western Section enterprise was begun in 1903 and completed in 1910, constituting a diversion from the Bow River near Calgary, and comprising approximately 1,600 miles of canals and ditches. The Central Section will receive its supply through the enlargement of a portion of the trunk system through the Western Section. The Eastern Section utilizes the Horseshoe Bend on the Bow River, about three miles southwest of the town of Bassano, the water for irrigation purposes being supplied through an intake at this point, and acquiring distribution through a system of canals, reservoirs, etc., the total mileage of canals and ditches reaching 2,500. Innumerable drops, headgates, flumes, syphons, bridges, etc., to a large extent built of reinforced concrete and brick, are included.

To provide a sufficient volume of water, what is known as the "Bassano Dam" is constructed at Horseshoe Bend. It is a composite structure consisting of an earthen embankment some 7,000 feet in length, with a maximum height of 45 feet, a maximum width at base of 310 feet and a uniform top width of 32 feet; and a reinforced concrete spillway with a clear length between abutments of 720 feet, and a weir length of about 600 feet. It has a maximum height of about 400 feet to the overhead crest, and contains about 40,000 cu. yds. of concrete, with 1,250 tons of reinforcing steel. At its easterly end are situated the canal headgates, consisting of five openings, each of 20 feet, controlled by Ransome and Rapier's "Stoney" sluices, directing the discharge of 3,800 feet per second through a canal of 90 feet bed width, which discharges into a reservoir five miles distant, formed by an earthen dam 1,280 feet in length, and 35 feet maximum height. From this point a canal runs in a northerly direction distributing to about 90,000 acres. Another canal heading eastward branches out into distributaries taking care of the remaining portion of the Eastern Section.

Among the many interesting features, the one which probably stands out as the chief one, is the Bassano Dam, the gigantic proportions of which are merely mentioned in the above. Mr. Dawson's article is descriptive of the whole project, and a re-reading of it in conjunction with the following new information is advisable to adequately acquire an understanding of the development to date.

The construction of this Bassano Dam across the Bow River has been completed. As a result of its opening the Eastern Section, and its million acres of prairie land previously looked upon as of little or no use for agricultural purposes, is now placed under irrigation and will prove as productive as any other portion of the Dominion.

Fig. 1.—General View of the Bassano Dam, Headgates and Surroundings, Bow River, Alberta.

The gigantic work which has entailed the expenditure of several millions of dollars has been carried out under the supervision of Mr. J. S. Dennis, assistant to the president and head of the Department of Natural Resources.

About three years have been spent in this work; it is probable that the remaining portion can be built during the year 1914. The greater part of the earthwork for the canals, aggregating twenty million cubic yards, has been completed and operations well advanced on the principal structures. The remaining work to be done consists largely of placing over a thousand small structures, mainly wood, scattered over the irrigable tract covering the greater part of 2,000 square miles. A general review of the works as planned and constructed indicates that the location has been studied out on the ground with care and that the resulting position and alignment is in general superior to that found on most of the irrigating works of North America. The structures have been considered and planned with skill, evidently utilizing the experience and avoiding many of the errors of earlier similar works in the United States. The designs show careful study of the physical factors and an elaboration of detail well in advance of other works and embodying the best modern ideas. While, as in many engineering operations, there

may be individual differences of opinion, and possibility of criticism of details, yet it is evident that safety and permanence has been the primary consideration. Reviewing the structure as a whole, it may be said that, while elaborated with high engineering skill, there has been a proper regard for economy in construction and in the future maintenance of the system.

The water supply is derived, as stated, from Bow River, being protected by compliance with the necessary legal requirements. The quantities, as shown by the records of the Dominion Government, are notably large, the river receiving the drainage from over 5,000 square miles above Bassano. It has a heavy spring flow, the highest stages being reached between June 15th and August 15th, and thus furnishing an ample quantity for conveyance through the main canal to the storage reservoir located within the irrigable tract. This provision of storage for a part of the irrigable area and in the vicinity of the farms is notable as an assurance against certain classes of operation troubles.

The low water surface in Bow River is raised approximately 40 feet by the Bassano Dam, located 83 miles east of Calgary. This is built with regard to economy of material and of the so-called "Ambursen type" with heavy floor on the bed of the stream, protected by suitable cut-off walls. Upon this are erected buttresses carrying a sloping deck with apron, the whole designed to pass 100,000 cubic feet of water per second with extreme height of 13 feet above the crest. The concrete portion of the dam is prolonged westerly within the Horseshoe Bend by an earthen dyke with maximum height of 45 feet and length of 7,000 feet, as mentioned above, containing about 1,000,000 cubic yards. At the time inspected, the dam was approaching completion but the final closure had not been made. There was every indication, however, that this could be successfully accomplished within a few days. The headgates form a part of the dam and are practically completed.

Extending easterly from the dam is the main canal, five miles in length, partly in a deep cut of 70 feet bottom width and which, being made in earth of somewhat treacherous character, has given considerable trouble. In this respect it is comparable with a number of similar deep earth cuts which have been made and successfully maintained under similar conditions on canals in Montana and adjacent areas. This cut will presumably continue to be a source of annoyance and some expense, but is simply one of the many difficulties which appear to be unavoidable. Beyond the eastern end of this cut, the main canal, the capacity of which is 3,800 cubic feet per second, divides, the smaller portion, with bed width of 30 feet and capacity of 800 cubic feet per second, turning toward the north, while the larger branch, with capacity of 2,200 second-feet, continues toward the east. On the northern branch and its subdivision are many important structures, such as drops and flumes, but the larger number of these is on the eastern canal, and its subdivisions.

The most notable of the canal structures is the Brooks Aqueduct, 10,000 feet in length, with capacity of 900 second-feet, crossing a broad low depression. At the time visited, this was in the initial stages of construction, the concrete pedestals being in place and the wooden forms for pouring a portion of the aqueduct being partly erected. The design of this aqueduct is novel, but evidently based on careful study and with a view to permanence and economy of material. Practically all of the larger structures in the Eastern Section have been, or are being built of concrete, the chief exception being several large wooden flumes, built in localities where it is evidently more economical to use wood than concrete and steel. The drops in the canal are of substantial design. They are of concrete and embody features found to be necessary for their permanence. There is a considerable number of high earth fills built in place of flumes. It is obvious that great care must be used in wetting these and in bringing them into service, but there is every reason to expect that with proper precaution these raised portions of the canal will be permanent and can be maintained at less expense than the ordinary timber conduits. The smaller structures for distributing water to the farms or groups of farms, numbering over a thousand, have not yet been put in place, but the parts are being assembled at various lumber yards from which they will be distributed as needed. It is believed that good practice justifies

Fig. 3.—View from Westerly End of Dam.

the building of these hundreds of smaller structures of wood, even though they must ultimately be renewed within ten or twelve years. In some of the projects in Montana concrete has been used for this purpose, especially where railroads or other means of transportation are available and gravel could be had nearby. It is found, however, that as a new country develops, it is necessary to make a number of changes in the distribution system with the result that by the time the smaller wooden structures need renewal, there exists such a difference in methods and of transportation possibilities that the wood can then be replaced to advantage with concrete. At the same time the plans can be modified to suit the developments which have taken place. Thus, it results, as above

stated, that the use of wood in these smaller structures is in accordance with good practice and sound economy.

The area for which water is being provided, in general, is undulating and with notable slopes towards Bow and Red Deer Rivers. There is a number of distinct drainage lines traversing the country and the topography, as compared with that of most of the plains region, is favorable for a relatively rapid run-off of excess water. There is a considerable number of partly closed depressions, such as are characteristic of all glaciated regions. Provision has been made for draining many of these or for connecting them up, affording outlets for the surplus waters. Thus the main drainage system has been provided in part by nature and in part by artificial means. It is probable that as irrigation progresses and water is used lavishly, as is habitually done by the new-comers, extensions and possible deepening of some of the drains will be necessary. In this connection experience has shown that, as far as possible, plans should be made in advance for delivery of water by rotation, allowing certain distributaries to be periodically dry so as to reduce the seepage of water from them and to permit the irrigated lands to be relieved from excessive saturation. The first problem under the prevailing climatic conditions is first to induce the farmer to exercise forethought and to use water at the right time; the second, and even more difficult, is to get him to appreciate the danger of using too much water. He is apt to assume that if a little water is a good thing, a large quantity is better, whereas, the larger quantity may be injurious to his crop and to his neighbors' fields, and ultimately may necessitate large, and otherwise unnecessary expenditures for deepening and extending the drains. In order to prevent the occasion for these large expenditures for drainage arising in the future, arrangements are made on many of the new irrigation systems to deliver water on a measured basis, a certain minimum quantity being obtained at a flat charge assessed on all irrigable lands. For example, 50c. or $1 is to be paid, usually in advance, whether the irrigable land receives water or not, and for this, say, one acre-foot can be had. This minimum is set at the amount which is considered to be necessary for the production of the average crop under ordinary conditions, but it is not enough to result in water-logging the soil and in the consequent demand for drainage. For all quantities in excess of this minimum an additional charge is made and collected in advance. The result is that the irrigator, being called upon to pay out his money when he demands more water than minimum, considers very carefully as to whether he really needs the water. As a rule, he concludes that he can get along with a smaller amount than he otherwise would deem necessary. Experiments have shown that the largest crop yields are obtained with the minimum amount of water applied, consistant with suitable plant growth, and that while many crops are tolerant of considerable amounts of water yet the yield is reduced in quantity and quality of such excessive application. The production of the best crops is, therefore, very closely joined with the conditions of carefully measured supply and the consequent avoidance of the necessity of incurring large expenditures for drainage of the irrigated lands. The plans already made and largely executed for the main drainage lines appear to make ample provision for future contingencies. If the operation of the distributing system is carried on in accordance with the principles above noted, it is probable that any considerable large future expenditure can be avoided.

Fig. 2.—Massive Abutment and Pier Construction, Bassano Dam.

The works have been advanced to a point where it is assumed that the final cost will be about $20 per acre of land irrigated, for approximately 440,000 acres. This may be exceeded somewhat, but even if the cost rises to $25 per acre, or even more, it will still be less than the average of similar work executed in the United States. There the prices of recently constructed large systems, with storage and with principal structures of concrete, average from $40 to $50 per acre irrigated. The relatively low cost of the Eastern Section, compared to the permanence of the work, is due to the large extent of the area irrigated and the simplicity of the entire system. It is understood that the preliminary surveys for the work on the Eastern Section of the Irrigation Block, showed as originally reviewed, a cost of approximately $16 per acre for 540,000 acres. Later it was found that the irrigable acreage must be reduced to about 440,000 acres, with accompanying increase in cost per acre. There is a probability at present that a new classification made on a more strict basis, taking the detailed surveys of each quarter-section, may cause a further shrinkage of the irrigible area with a corresponding increase in acreage cost. Whatever this cost may ultimately be, it is evident that the works are well worth the expenditure and that, as stated, the cost per acre will be less than that of most well-built large systems in the States to the south. In explanation of the fact that the final cost will exceed the preliminary estimate of $16 per acre, it may be stated that there has been a general advance in costs of construction, accompanied by a demand for a larger number of permanent structures and greater elaboration of detail. The greatest factor, however, in increasing the acreage cost is that due to the general decrease of acreage upon which the cost must be distributed, due to the more rigid exclusion of small scattered tracts of land considered as non-irrigible. The era of low costs in irrigation construction has passed. Throughout the country the same condition prevails, namely, that the estimates of the engineers as to what might have been accomplished four or five years ago under the then existing conditions, are being to-day exceeded in the actual operations. Engineers, like other professional men, are not prophets and must base their figures upon the experience of the past with such allowance as have proved wise; the increase in cost such as has taken place could not have been safely predicted.

The Eastern Section includes a million acres, out of which there has been selected approximately 440,000 acres, lying in an altitude of from 2,300 to 3,300 feet, and which may be irrigated from the system as planned and nearly completed. The tract as a whole is a part of the Northern Great Plains, the surface of which has been modified by glacial action, with resulting heavy underlying deposits of sand and gravel, and particularly of clay, interspersed with large and small boulders. The resulting top soil on the glacial deposits is frequently loamy, usually very rich, and in places slightly sandy. Everywhere seen it is of suitable depth and quality for excellent crop production. The native vegetation, largely of various grasses, grows luxuriantly wherever there is an adequate supply of moisture.

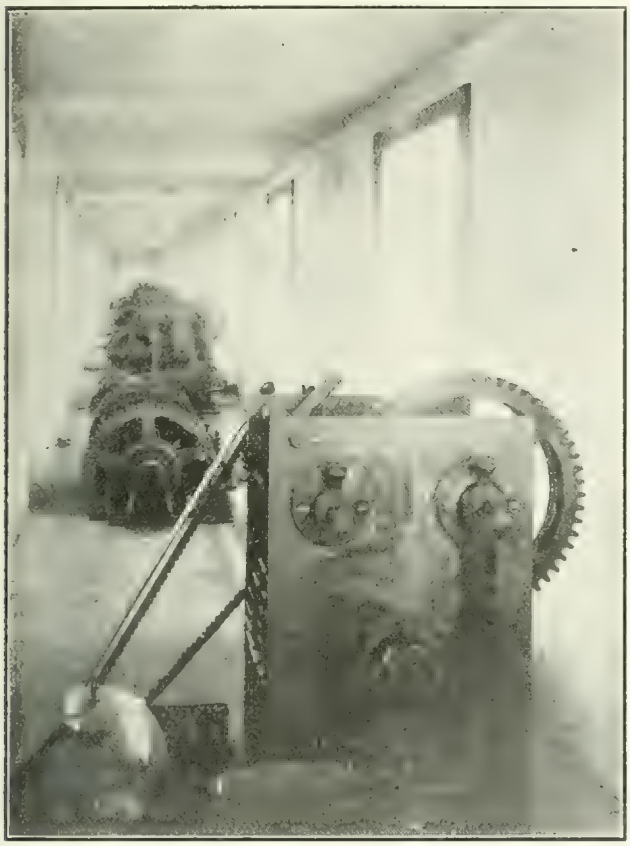

Fig. 4.—Interior of Power House for Operation of Headgates.

Contour maps have been prepared covering the lands which can be reached by the canals. In the study of these maps the rougher, or more gravelly tracts have been eliminated as non-irrigable, leaving for consideration only those portions which appear to have an ample depth of good soil. There is no doubt as to the capability of these irrigable areas to produce highly remunerative crops if properly handled.

The climate, owing to the lower altitude of the Eastern Section, is somewhat more favorable than that of the Western and the growing season is longer. It appears to be peculiarly well adapted to mixed farming or dairying with raising of forage crops.

It may be stated that, taking this Eastern Section as a whole, with its water supply, soil, engineering plans and construction, it stands well in the front of similar enterprises. Its future success, as far as these are concerned is assured. The great problem now is that of securing a prosperous and contented agricultural population.

RAILWAYS IN THE MALAY PENINSULA.

The total mileage of railway lines open to traffic in British Malaya, including leased lines, on December 31st last was 734 miles, an increase of 175 miles, and as there were 92 miles of sidings, the total mileage of railroad in operation at the close of the year was 826. The expenditure on new lines under construction and surveys was £529,027, and on special services £273,077—a total of £802,104. For the current year the federal estimates provide for an expenditure of £2,168,-831 on railways against £1,513,171 in 1912, the amount for special services on capital and revenue accounts and for construction being estimated at over £1,500,000. It will thus be seen that this important department is endeavoring to keep ahead of the trade requirements of the country, and the encouraging development that has occurred in the eastern State of Pahang during the past year is one evidence of the expansion that follows railway extension. The growth of trade in the other States has led to the issue of instructions for a survey of the Port Swettenham-Kuala Lumpur line with a view to the duplication of the line. A survey has been begun on the Port Dickson line for its improvement. The duplication of the line between Singapore and Bukit Timah is begun, and preparations are in progress for other extensions in the Federated Malay States. One of the more important works in contemplation is the construction of a bridge across the Straits of Johore, about three-quarters of a mile wide. In the State of Kelantan marked progress is being made with the line which eventually will link up the British Malaya and Siamese railway systems, and the general manager expects to be able, by March next, to transport goods from Tumpat on the coast to Tanah Berah on the Kelantin River. Orders have been placed for the purchase of a tug and lighters for the transport of goods from steamers to the railway wharf at Tumpat. Mention of these matters gives the opportunity of calling attention to the enormous changes in progress in a region which, a comparatively few years ago, was practically unknown to white men. The linking up of the Malayan and Siamese Railways will probably be followed by connections with Burma and Indo-China, and it is not too sanguine a view to contemplate the time as not very remote when it will be possible to travel by rail from Singapore in the extreme south to Burma or China. In Malaya, where British influence is paramount, the work certainly proceeds apace.

A modification of the usual method of estimating phosphorus in low-phosphorus steel is given in *Journ. Soc. Chem. Ind.*, July 31st, 1913. The yellow ammonium-phosphomolybdate precipitate, obtained from the steel in the usual manner, is washed with 1 per cent. nitric acid until free from iron, and the nitric acid is washed out by means of 1 per cent. potassium-nitrate solution until the washings are free from acid. The filter and precipitate are then transferred bodily to a 200 c.c. flask, 20 c.c. of $N/10$ sodium-hydroxide solution and 2 drops of phenolphthalein are added, and the excess of alkali is titrated with $N/10$ hydrochloric or nitric acid until the last drop completely removes the pink color. The following reaction takes place:—

$$(NH_4)_3PO_4.12MoO_3 + 24\ NaOH =$$
$$(NH_4)_3PO_4 + 12\ Na_2MoO_4 + 12\ H_2O.$$

Hence, 1 gram of phosphorus is equivalent to 31 grams of sodium hydroxide, or each c.c. of $N/10$ sodium hydroxide is equivalent to 0.000129 gram of phosphorus. Thus, when working with 1 gram of steel, the percentage of phosphorus is obtained by multiplying by 0.0129 the difference between 20 and the number of c.c. of acid used in titrating the excess of alkali. The method has been found to give accurate results, in excellent agreement with those obtained by the gravi-metric method.

COMMERCIAL LINSEED OILS.*

By A. Gordon Spencer, B.A., M.Sc.,
Chief Chemist, Canadian Inspection and Testing Laboratories, Limited.

IT was about the 12th century that the essentially exclusive properties of linseed oil were discovered and developed by the monks who used to occupy their leisure time in oil painting, in illuminating theological treatises and writings before the art of the modern printer was developed, or possibly even thought of. Their early experiments and patient investigations showed them that the oil extracted from the flax seed was much superior as regards ease of extraction and preparation as well as in beauty and durability of the finished painting. Previous to this date; in fact, before the Christian Era, there are records and descriptions of the medicinal properties of certain decoctions of linseed and of the resultant oil. Its actual commercial use, however, did not begin until the later period above mentioned and since that time no substitute has yet been found which possesses all of the properties of linseed oil which to-day make it so valuable not only to the artist but to the painter, printer, as well as to many manufacturers. Many claims are made for various so-called linseed oil substitutes, that they are fully equal to, if not better than, linseed oil, but so far as we are aware their claims have not yet been completely proven.

Uses of Linseed Oils.—Linseed oil in some form or other plays a prominent part in the manufacture of linoleum and oil cloth, in dressing of leather, in the varnish for patent leathers and carriage tops, in oil-clothing, in printers' inks, certain kinds of soap, rubber substitutes, etc., etc. Its principal use, however, is in the various branches of the painting and decorating trade.

Preparation.—Linseed oil is obtained from flaxseed by grinding and extraction. In the early stages of the industry the seed was crushed and ground and the oil extracted by pressure at ordinary temperatures. The resulting oil contained no "foots," was quite light in color and was of excellent quality for immediate use. The percentage of oil extracted, however, was not very high, and a large proportion was left in the oil cake. By cooking or "tempering" the ground seed with steam the plant cells are broken up more thoroughly and a more complete extraction of the oil is obtained, so that at the present time practically no cold-pressed oil is made, but all the oil is hot pressed. The product differs from the cold-pressed oil in that it contains considerable gummy mucilaginous matter commonly termed "foots," part of which is subsequently removed by settling and filtering before being stored as raw linseed oil.

A small quantity of oil is also obtained by the use of solvents with subsequent evaporation of the latter. This oil, however, is not as good as that obtained by pressure and the residual oil cake which in the case of the pressed cake always commands a good market price as a stock food, is of very little use for this purpose, as one of the chief food constituents, viz., the oil, has been almost completely removed. It is also said to be found unpalatable on account of the last traces of the solvents not being completely removed.

*Paper presented before the local section of the Society of Chemical Industry in Montreal, December 12, 1913.

Raw Linseed Oil.—This is the oil as it comes from the storage tank and which is used by the consumer without any further preliminary treatment. Its value to the paint and varnish maker, as well as in the other industries in which it is used, is due to its characteristic property of drying quickly and completely to a hard, tough, elastic and durable film upon exposure to the atmosphere. The nature of the film produced upon drying depends not only upon the maturity of the seed, as well as its freedom from other seeds; but also upon the carefulness with which the oil is processed and stored. It has been found that seed from two to six months old gives a less viscous and turbid oil than fresh seed. Mature seed gives a lighter oil than young seed. The yield of oil is also higher in the former. According to Ennis (Linseed Oil and Other Seed Oils, p. 220 footnote), there is a slight (though progressive) improvement in oil from seeds derived respectively from the American Northwest, India, Morocco, Holland and the Baltic, evidenced by the higher iodine absorption value. The Calcutta seed is stored in pits dug in the ground and contains a large amount of clayey dust; there is very little other impurity. It produces a very light oil, well adapted for varnish purposes. Bombay seed is very difficult to grind, but makes a fine oil, which, however, cannot readily be "bodied down" by heat.

One of the most important requirements, however, in the production of a good raw oil is a long period of storage before being shipped and consumed and this applies especially to hot-pressed oil. The initial filtration of the oil as it comes from the presses does not completely remove the "foots," but they continue to settle out for an indefinite period. As the quality of the oil depends to a great extent upon its freedom from these "foots" it is essential that it be stored or tanked for a sufficient time to allow them to be deposited as completely as possible. The quality of some of the special oils, as well as their ease of preparation, are also greatly affected by the amount of "foots" remaining in the original oil.

Linseed oil, on exposure to air, absorbs oxygen with the formation of a neutral substance insoluble in ether called linoxyn. Different statements are made as to the composition of linseed oil and several theories have been put forth regarding the changes which take place. It is generally believed that it is in part composed of the glycerides of linoleic, and oleic acids. Hazura claims to have isolated linolenic and isolinolenic acids. Bedford, on the other hand, assumes that the chief constituents are glycerides of α-linoleic, β-linoleic, α-lenolenic and β-linolenic. It is evident, however, that further researches are required to satisfactorily establish the composition of the fatty acids.

Raw linseed oil, after filtering and storing, while it is the staple product, does not fully meet all the different requirements of the consumer. It is therefore treated and modified in various ways to meet these special requirements and to these oils special trade designations are given. They may be broadly divided into boiled oils and refined, or special oils and among others we would mention:—

Boiled oils: Kettle, ordinary, heavy and extra pale.

Special: Heavy raw oil, varnish oil, refined or bleached oil, and aged oil.

Boiled Oils.—Each of these boiled oils has its special uses, but they are all made by boiling the oil with prepared dryers under very careful control and supervision. The differences in the properties of the resulting oils are caused by variations in the oils used, in the dryers, or in

the methods of boiling and these differences are by no means small, as will be described later. The dryer acts as a sort of catalytic agent in carying oxygen from the air to the oil. Only a very small quantity of dryer is required, in fact an excess of dryer is harmful in that it causes the oil to dry too hard and the resulting film is thereby rendered weak and brittle. Sufficient must be present, however, or otherwise the longer period of boiling which would be required would be equally harmful and produce not only a dark colored oil, but also one of poor quality. Each manufacturer has his own special and carefully preserved methods of making these oils, so that we can only mention their general properties and give such other information as has been made public in the literature.

The principal dryers used are compounds of lead and manganese. The combination of the two makes a better dryer than either material alone. †A bodied oil prepared with lead contracts in oxidizing; one with manganese expands. The most economical properties are stated to be 0.05 per cent. of manganese dioxide and 0.20 per cent. of lead oxide. (P.L.O.) in the boiled oil. When either constituent is used alone the time of drying is increased. It is possible that one of the constituents is more active in absorbing the oxygen from the air, while the other is of particular value in giving it up to the oil. An intermediate transfer of oxygen from lead to manganese, or vice versa, must then occur. Among the dryers used are manganese resinate, mangano-lead resinate, manganese linoleate, mangano-lead linoleate, manganese chloride, manganese borate, lead acetate, lead borate, lead linoleate, lead resinate, manganese sulphate, manganese acetate, manganese oxalate, lead sulphate, zinc sulphate, Prussian blue, Cobalt oxide, etc. In some cases they are used in the dry state, but in this country they are usually in the form of concentrated liquid dryers.

Kettle Boiled Oil.—In the old days all boiled linseed oil was prepared in an open kettle heated by direct heat from a fire built underneath it. This has to be carefully done, not only on account of the danger from fire, but also on account of the possibility of overheating and damaging the quality of the oil. If, properly prepared, however, it is of the highest quality and usually commands a somewhat higher price than ordinary boiled oils. It is usually slightly darker in color chiefly on account of the higher temperature to which it has been raised, and is by far the largest seller, in the province of Ontario especially.

Ordinary Boiled Oil.—This is much the same as the kettle-boiled oil except that it is heated in steam-jacketed tanks or kettles and larger quantities of oil are taken in a batch. The oil also is probably not raised to such a high temperature, although if carefully prepared should be of (good) quality for most purposes. On account of the lower temperature used in its preparation it is lighter in color than the kettle-boiled. A very large percentage of the boiled oil of commerce is made by this process.

In addition to these principal grades of linseed oils there are certain other special oils each of which has its uses. Among these we would mention:—

Heavy Raw Oil.—This is a raw oil treated in such a way as to make it less fluid and with more body to it so that it can hold up a heavy pigment in suspension better than ordinary raw oil. The pigment does not settle so quickly and the paint does not have to be stirred up so much while it is being used. The coat of paint is therefore more uniform in appearance and more pleasing results are obtained. It should dry in a slightly shorter time than ordinary raw oil, but not as quickly as boiled oil. Its principal use so far is in the grinding of heavy pigments by the paint manufacturer, although we do not see why it should not be equally valuable to the painter himself.

Heavy Boiled Oil.—This has much the same qualities as the heavy raw oil, except that it dries more quickly and is used by the paint manufacturer and painter where he requires a boiled oil for heavy pigments and where quick drying is essential.

Extra-Pale Boiled Oil.—This is a light colored boiled oil with specially quick drying properties and is used in the grinding and manufacture of light colored paints and in enamels. A low temperature in boiling as well as special ingredients in the dryers used are the means taken to avoid the darkening of the color.

Varnish Oil.—As its name signifies it is used for the manufacture of varnishes of various kinds. It is not a boiled oil, but is treated in such a way that it will not "break" by any application of heat. When ordinary oil is heated up to a moderately high temperature a flocculent gummy precipitate called the "break" separates out. An oil varnish consists of resins dissolved in linseed oil at high temperatures, the solution being afterwards thinned with a volatile solvent. Owing to the high temperatures used in varnish preparation, the varnish oil must have its breaking property entirely eliminated; but on account of the expensive and elaborate applications of oil varnishes, the oil must retain its durability and elasticity unimpaired by the treatment given to prevent breaking. Each linseed oil manufacturer has his own particular method by which he removes this breaking property, the quality of the product depending partly on the process employed, but largely on the careful attention given to the oil while it is undergoing the treatment.

Refined Oil.—This is an oil which has been bleached and made of a yellowish white color. It is especially useful in the grinding of white paints as it does not injure the color of the pigment. It usually does not "break" on heating, because the breaking element in most cases has been removed. Strictly speaking, however, it is not a varnish oil, although some brands may be used for this purpose if combined with a suitable dryer. Bleached oil, like raw, dries slowly, and it is customary to mix suitable dryers with it. The process of bleaching has to be carefully controlled since if it is carried too far it injures the good qualities of the oil. For this reason a very white oil is not to be recommended.

Aged Oil.—This is a thick heavy oil which has been partially oxidized and the "break" removed. It dries, therefore, somewhat more quickly than ordinary raw oil. Its special use, however, is in the manufacture of patent leather and linoleums, in which industries large quantities of it are used.

The chemical characteristics of these different commercial grades of linseed oil are rather interesting, and we have determined the specific gravities and iodine values of samples of each, most of which have been kindly furnished to us by the Dominion Linseed Oil Company, and made from No. 1 Canada Western flaxseed. The screw-pressed raw oil was supplied by the Sherwin Williams Company:—

†Ennis, loc. cit. p. 239.

Grade of oil.	Specific gravity. at 15.5°C.	Iodine value. (Hanus)
Hot pressed raw oil	.9339	192
Screw pressed raw oil (4½ years old)	.9389	187
Kettle boiled	.9421	182
Ordinary boiled	.9361	184
Heavy raw	.9800	149
Heavy boiled	.9790	140
Extra pale boiled	.9384	183
Varnish	.9350	192
Refined	.9343	190
Aged	.9047	150

The specific gravity of raw oil lies within the limits of about 0.930 and 0.950, depending on the grade and condition of the seed as well as on the temperature employed in cooking the seed. Exposure to the air also increases the gravity by reason of the polymerization and oxidation of the oil. The specific gravity of the boiled and special oils is higher than that of the raw oil as can be seen in the above table, particularly in those which have been partially oxidized, notably the aged, heavy raw and heavy boiled oils. The iodine value as would be expected is lower in a corresponding manner.

In connection with the above we might further mention that we have quite recently been furnished with two samples of oil from the same lot of seed, one of them being obtained without previous cooking of the meal and the other in the regular way. The color of the cold pressed oil is somewhat paler than the other, the taste is quite pleasant with a nutty flavor, while in the hot pressed oil the flavor is somewhat rancid and unpalatable. There is also less foots in the former than the latter, since most of the "mucilage" is retained in the cake. The specific gravity and iodine value of each are not very different, although the former is somewhat lower in gravity and higher in iodine value.

Grade of oil.	Specific gravity. at 15.5°C.	Iodine. value. (Hanus)
Cold pressed oil	.9344	191
Hot pressed oil from same seed	.9352	190

A PORTABLE SUB-STATION FOR A COAL MINE.

The Berwind-White Coal Mining Company, Windbar, Pa., has recently added a 400-k.w. Westinghouse portable sub-station to its equipment and is making a very interesting use of it.

A sub-station consists of apparatus for changing alternating current into direct current, and is generally necessary in mining work, because direct current must be used for haulage in mines, but cannot be transmitted economically over long distances. Hence, when the mine is located some distance away from the power station that serves it electric power can be transmitted more efficiently as alternating current at a high voltage and then transformed to direct current in the sub-station.

The company is developing its outlying properties very rapidly, and need direct current at points where permanent sub-stations are not yet erected. In order to prevent delays in the development the use of a portable sub-station was decided on. This sub-station has the same equipment that a permanent installation has, namely, transformers to step down to a moderate value the high voltage of the current received from the transmission line, a switchboard, and a rotary converter, which receives alternating current and delivers direct current. This apparatus is mounted in a car resembling an ordinary freight car.

When the work at a new development reaches the point where direct current is necessary the portable sub-station is hauled out to the workings, connected to the alternating current transmission system, and is started to work generating direct current. When the permanent sub-station is built the portable one becomes unnecessary and is taken to the next development.

Fig. 1.—Portable Sub-Station, Fully Equipped to Serve Until Permanent Stations are Built.

A further use of this sub-station is to provide insurance against shut-downs. If accidents occur at any of the permanent sub-stations, the portable outfit is sent to carry the load until repairs are completed. One portable sub-station, therefore, is practically the equivalent of a duplicate set of apparatus at each permanent sub-station.

The whole question of the pollution of the Niagara River from Lake Erie to Lake Ontario is involved in the Western New York Water Company's action against the city to prevent this discharge of effluent from the municipal filtration plant into the river. If the city is enjoined from dumping refuse into the stream, then an effort will be made to prevent Buffalo and the Tonawandas from polluting the Niagara. Briefs on the city's motion for a settlement of the issues in the case have been presented to Justice Pound in Buffalo. The private company claims that the effluent from the municipal plant so pollutes the river that it materially increases the cost of filtering water at the company's plant. The city claims that it puts nothing into the river that was not taken from it in the process of filtration, except the chemicals used in purifying the water. The city wants a jury to decide whether the use to which it puts the river is a reasonable one, and whether the effluent emptied into it makes the water any more unfit for domestic use than it otherwise would be. Corporation Counsel Anderson has prepared papers showing that the city of Buffalo is dumping 160,000,000 gallons of raw sewage into the river daily. Tonawanda pollutes the river with 4,500,000 gallons of untreated sewage. The city contends that the discharge into the river of about 300,000 gallons of water, which has been chemically treated, it reasonable when the uses to which other municipalities along the frontier put the river is considered. United States government reports will be used in the case to show the great degree to which the river is polluted by the sewage of up-river municipalities. Government experts are now conducting an exhaustive investigation of the situation, and it is likely that it will result in the discharge of raw sewage into the river being prohibited. The government experts will work out a plan of sewage disposal for Buffalo, the Tonawandas, Niagara Falls and other frontier municipalities that will likely involve the chemical treatment of the sewage before it is dumped into the international stream.

CONTENTS OF THIS ISSUE.

CANADIAN SOCIETY OF CIVIL ENGINEERS, ANNUAL MEETING.

Notices have been mailed by the Secretary of the Canadian Society of Civil Engineers that the annual meeting of the society will be held at Montreal January 27th, 28th and 29th, 1914. Many of the western members of the society desired to have the meeting held at Victoria, B.C. In a circular letter the Council recently asked the members whether they favored Montreal or Victoria as the place for the meeting. Unfortunately, an idea became prevalent that a vote was being taken. The Council never intended to surrender its privilege of saying where the annual meeting should be held, but merely desired to have an expression of opinion from the members in the matter.

While the "vote" favored Victoria, it was so by reason of the solid returns made from the West, but it was found that very few men east of Sudbury would be willing to go to Victoria this year. It was generally felt that it would be far better to hold a meeting in Victoria in 1915, because that is the year of the Panama Exposition at San Francisco, in conjunction with which there will be an International Engineering Congress. A large number of the eastern members will be willing to go to Victoria for a meeting next year, taking a side-trip to San Francisco.

It is possible that an effort may be made to hold the annual meeting of the society permanently at headquarters in Montreal, just as the annual meeting of the American Society of Civil Engineers is always held at headquarters in New York; but an adjourned meeting, or summer convention, would then be held each year in a different city, until such a convention had been held in every prominent city in Canada.

CRITICIZING A CRITIC.

In a letter to one of the Ottawa daily papers, Mr. Noulan Cauchon, of Ottawa, criticizes the Federal City Planning Commission for choosing Mr. E. H. Bennett, of Chicago, as their planning architect. Toward the end of a letter which occupies a full newspaper column, and which severely "roasts" the Commission for not appointing a Canadian in charge of the work, the following interesting paragraph is noted:—

"Personally, I have spent several years intensively studying, writing and lecturing on the problems of Ottawa and have produced a fairly complete scheme, the only one to date, and which has appealed to scientific and to popular audiences here. I offered to submit the result of these labors to the Commission. Though the offer was gratuitous and several of the commissioners promised to give a hearing they are remiss in having failed to do so, and in having neglected this source of information before deciding on their present course, a questionable one from the viewpoint of fairness at least."

In a postscript to the letter Mr. Cauchon admits his belief that his criticism is "keen" and "stimulating," and assures the Commission that they can count on a continuance of such criticism, as well as on "our continued devotion to the welfare of the plan."

The Commissioners are: Chairman, H. S. Holt, of Montreal; Mr. Frank Darling, of Toronto; Mayor Ellis, of Ottawa; Mayor Dupuis, of Hull; Sir Alexandre Lacoste, of Montreal; and Mr. Home Smith, of Toronto. All of these men, it must be remembered, are giving their

time to the scheme without any remuneration whatsoever. The work is under the direction of Mr. E. H. Bennett, of Chicago, as architect, and Mr. E. L. Cousins, of Toronto, as consulting engineer. A permanent engineer will likely be appointed next spring.

It is very important work, but it is in capable hands. Seven of the eight men who have the work in hand are Canadians. The eighth, Mr. Bennett, was born in England and educated in the finer arts in France. So, when the work is completed, one will truly be able to claim it "a work which in sentiment and in art should be the product of racial and national effort, an expression of ourselves as a nation," which Mr. Cauchon, in his letter to the press, claims to be a most important point.

MANITOBA WATERPOWERS.

Briefly stated, the main sources of dependable power in quantities sufficient for commercial use in the province of Manitoba are the Winnipeg River, the Grand Rapids and the Saskatchewan River, and the large rivers of the north, including the Nelson, the Churchill and the Berens. The power possibilities of the other rivers are limited and of local importance only.

The results of an investigation into the waterpowers of the province are contained in a report which has recently been completed by the waterpower branch, Department of the Interior. The report is now in the hands of Judge Robson, Public Utilities Commissioner of Manitoba, who is engaged in preparing a report for the Provincial Government on the question of waterpower development.

Probably the most interesting feature of the report is the data relating to the Winnipeg River. Its uniformity of flow throughout the various seasons of the year places it among the notable rivers of America. It has a range of 4 to 1 between maximum and minimum, under present natural conditions. Comparing it with the Ottawa River with a range of approximately 40 to 1, and with other rivers noted on page 101 of this issue, the Winnipeg River is shown to be unusually regular in its flow. Further, the flow can be rendered practically uniform by the regulation of the numerous storage lakes on its upper waters. In all it has over 5,500 square miles of lake area. It has a drainage basin of some 23,500 square miles, and its tributary, the English, drains an additional 20,500 square miles.

The report states that 400,000 continuous horsepower are capable of economical development within 80 miles of Winnipeg and within economic transmission distance of all the commercial centres of the province.

These facts obviously disclose an industrial future for the cities of Manitoba. An era of increased activity in manufactures will doubtless culminate in putting the various sources of power into harness.

LETTER TO THE EDITOR.

Fixed Carbon Test Valuable.

Sir,—The writer believes that the fixed carbon test is of considerable value in determining the quality of asphalt cement, and that to eliminate this test would place in open competition certain undesirable asphalts with well-known standard brands. As a result, with the use of these materials, the life of our asphalt pavements would be materially shortened.

It is a well-known fact that the fixed carbon test is one of the quickest and best for differentiating bitumens. It is also an excellent guide in determining the quality of same.

The asphalt containing over fifteen per cent. of fixed carbon would be looked upon with suspicion by the writer if it were to be used for paving purposes. With paraffine hydro-carbons, no fixed carbon is left on ignition, while the amount increases with each decrease in the proportion of hydrogen to carbon. Consequently, the fixed carbon test and the paraffine test are closely related.

If the asphalt produced from paraffine or semi-asphaltic petroleum shows a fixed carbon of over fifteen per cent., it is almost an absolute certainty that the bitumen would not be suitable for paving purposes. With careful manipulation, a pavement might be laid that would give good results for two or three years, but more than this it would not be reasonable to expect.

A high fixed carbon in any asphalt produced artificially shows carelessness in distillation, the material having been coked, burned or cracked whichever you may please to call it.

For example, California asphalts have been placed upon the market showing fifteen to twenty per cent. fixed carbon. These have proven absolutely worthless as paving materials. Other California asphalts showing twelve to fifteen per cent. fixed carbon have given fair results, whereas, as a matter of fact, California asphalt when carefully produced for paving purposes ought to show under twelve per cent. of fixed carbon.

In connection with this statement, it must be remembered that California asphalts are produced from asphaltic oils showing little or no paraffine. The best grades of Trinidad, Bermudez, Cubanel and Gilsonite bitumens show but from eleven to fourteen per cent. of fixed carbon. Grahamite and Albertite, on the other hand, give high fixed carbon results and neither of these materials would be satisfactory for paving purposes.

When it comes to the distillation of Mexican petroleums and the resultant asphalt shows over fifteen per cent. of fixed carbon, the product is to be looked upon with suspicion.

The amount of fixed carbon in a coal measures to a large extent its burning quality. The fixed carbon in an asphalt shows the character of the material in an entirely opposite manner. The higher the percentage of fixed carbon, the less life there is to the asphalt.

Generally speaking, the asphalt produced from petroleum distillation with a high per cent. of fixed carbon, is a hard, brittle product with a high melting point and not suitable for asphalt pavements.

Mexican petroleums, high in paraffine, when carefully produced for asphaltic purposes, ought not to show a high amount of fixed carbon. Nevertheless, numerous of these products do show a high percentage of same.

Very few high carbon Mexican asphalts have been in use for over two or three years and time alone will prove their value.

In regard to the objection that the fixed carbon test is so uncertain, this is more or less true, due to carelessness of operator.

A definite method has been adopted by the American Chemical Society which is as follows: Place one gram of pure bitumen in a platinum crucible weighing from twenty to thirty grams and having a tightly fitting cover. Heat over the full flame of a Bunsen burner for seven

minutes. The crucible should be supported on a platinum triangle with the bottom six to eight cms. above the top of the burner. The flame should be twenty cms. high when burning free and the determination should be made in a place free from draughts. The upper surface of the cover should burn clear, but the under surface should remain covered with carbon. The residue, minus the impurity of ash in the pure bitumen, is the per cent. of the volatile hydro-carbons, excluding the inorganic matter.

This test should be conducted in a hood in duplicate with Bunsen burners protected by a collar. The two tests upon the one sample should be made at the same time. Then, and then only, will concordant results be obtained.

The carbon tetrachloride test which, it is claimed, answers the same purpose as that of fixed carbon, is unreliable. While a high amount of carbenes conclusively proves that an asphalt has been "burned," yet the test is not one that can be absolutely depended upon. In order to be of value, both the carbon tetrachloride and fixed carbon tests are necessary.

In conclusion, I wish to say that simply for the sake of commercializing a few products, it is to be hoped that the highly valuable fixed carbon test will not be eliminated to the detriment of our future asphalt pavements.

HOWARD C. HOTTEL,
Consulting Asphalt Chemist.

Trenton, N.J., Dec. 24, 1913.

CANADIAN PRODUCTION OF IRON FOR FIRST HALF YEAR.

THE American Iron and Steel Association reports that the production of pig iron in Canada in the first six months of 1913, including ferrosilicon and ferrophosphorus, amounted to 545,981 gross tons. The output in the whole of 1912 was 912,878 tons. The production of pig iron in the two halves of 1912 is not available. Of the total in the first six months, 532,431 tons were made with coke and 13,550 tons with charcoal, coke and electricity, etc. The production of basic pig iron in Canada in the first half of 1913 amounted to 292,625 tons, bessemer pig iron to 125,052 tons, and foundry pig iron, ferrosilicon, ferrophosphorus, etc., to 128,304 tons. Forge pig iron was not reported. Of the 545,981 tons of pig iron produced, 345,810 tons were delivered to mixers, openhearth furnaces, etc., in a molten condition, 141,680 tons were sand cast and 58,491 tons were machine cast.

On June 30, 1913, Canada had 20 completed blast furnaces, of which 13 were in blast and seven were idle. Of the total 16 furnaces usually use coke for fuel and four use charcoal. In the first half of 1913 two plants made ferrosilicon and ferrophosphorus in electric furnaces. During the first six months of 1913 the number of furnaces actually in blast during a part or the whole of the period was 15, of which 14 used coke for fuel and one used charcoal. The average number of days the 15 furnaces ran was 167.6, which would give an average make per furnace day of 217 tons.

One entirely new furnace was completed in Canada during the first six months of 1913, No. 7 coke furnace of the Dominion Iron and Steel Co., at Sydney, Cape Breton, Nova Scotia, which was first blown in on May 22. It has an annual capacity of 91,250 tons of basic pig iron.

Two blast furnaces were being built in the Dominion on June 30. One of these furnaces will be operated by the Canadian Furnace Co., Limited, at Port Colborne, Ont. When completed it will be 85 x 19½ ft. and will have an annual capacity of about 125,000 gross tons of bessemer, foundry and malleable pig iron. Lake Superior ore and Connellsville coke will be used. It is almost ready to blow in. The other furnace is being built at Parry Sound, Ont., by the Standard Iron Co., Limited, of Montreal. When completed it will be 60 x 12 ft. and will have an annual capacity of about 36,000 gross tons. Charcoal will be used for fuel. Hematite and magnetite ores from Michigan and Ontario will be used. The Standard Iron Co. also operates a charcoal furnace at Deseronto, in Ontario. The annual capacity of the 20 completed blast furnaces on June 30, 1913, was 1,391,550 gross tons, and of the two building furnaces 161,000 tons, a total of 1,552,550 tons.

SPECIFICATIONS AND METHODS OF TESTS FOR CONCRETE MATERIALS.

THE following is the report on specifications and method of tests for concrete materials of the standing committee of the American Concrete Institute, which, as announced in these columns last July, is the new name of The National Association of Cement Users, as authorized at its last convention. The committee comprises Sanford E. Thompson, chairman, consulting engineer; Cloyd M. Chapman, engineer of tests, Westinghouse, Church, Kerr and Company; William M. Kinney, assistant inspecting engineer, Universal Portland Cement Company; A. N. Talbot, professor of Municipal and Sanitary Engineering, University of Illinois; and G. W. Wise, engineer of tests, Department of Public Works, Philadelphia. Its work during the past year has included:—

(a) Layout of tests of concrete for various laboratories with a view to recommending in a later report standards to be followed in making concrete specimens.

(b) Investigations and compilations of methods of tests of fine aggregate employed by various laboratories.

(c) Studies of results of tests of sand mortars with a view to recommending in a subsequent report uniform methods of test of fine aggregates.

The following report emphasizes the necessity for more rigid requirements for the acceptance of concrete materials and for routine tests of the materials and the concrete. It appeared recently in Vol. 1, No. 1, of the Journal of the Institute.

Tests of Concrete.—Tests of the individual materials are not sufficient for determining the quality of the concrete made from them. A certain sand may give satisfactory results with one brand of cement and prove a failure with another. A sand of a certain granulometric composition may require an entirely different proportioning with one coarse aggregate than with another, or may be unsuited for use with it because of the sizes of the grains.

The committee recommends that for all important structures, such as dams, conduits, and buildings, specimens of concrete be made up in advance of the actual work from materials which it is proposed to use in the work. These specimens should be made under laboratory conditions so as to obtain uniformity in mixing and storage, and with the same consistency which is to be used in the proposed structure. The specimens

should be stored in moist atmosphere and compressive tests made at the age of 28 days and also at other periods if practicable. The final selection of the materials and the proportions to be adopted should be governed by the results of these tests.

The tests now in progress in different laboratories under the auspices of the committee are expected to furnish data from which definite recommendations may be made as to the size and shape of the specimen. The joint committee on concrete and reinforced concrete recommend cylinders 8 inches diameter by 16 inches high. Where it is impracticable to adopt this size, a 6-inch cube or a cylinder 6 inches diameter and 6 inches high is tentatively suggested for use with aggregates under $1\frac{1}{2}$ inches in size. It must be borne in mind that specimens of this shape may give from 10 to 20 per cent. higher strength than the same materials made into oblong cylinders or prisms.

Layout of Concrete Tests.—In order to obtain well-defined information with reference to the effect of different shapes and sizes of specimens and different mixtures, the committee has laid out in very full detail a number of series of tests. These specifications have been sent to various laboratories throughout the country and accepted by them as a part of their routine tests for the coming year. The results of these tests will be presented in the next report of this committee.

Tests of Concrete Materials.—Tests of materials for use in mortar or concrete may be divided into two general classes:—

(1) Tests for acceptance.

(2) Tests for quality.

These two divisions frequently merge into each other because in many cases the special characteristics of a sand may render it unfit for certain work, although it may satisfactorily pass a standard test for acceptance.

The most important questions to be asked in regard to a material are: (a) Can it be used? (b) In what proportions must it be mixed with the other materials to produce the required qualities in mortar or concrete? (c) Can another material of the same class be substituted with greater economy?

For small structures and, in fact, frequently for larger ones where the sources of supply are limited, the all-important question is a combination of the first two, namely, can a certain material—and this applies most frequently to the fine aggregate or sand—be used, and in what proportions to give the desired quality of concrete or mortar? For structures where the volume of the concrete is large so that the economy of the proportioning is paramount, or for small structures subjected to special conditions—such as the effect of sea water—the cement and aggregates should be thoroughly studied also and special tests made to determine the most economical or the qualifications for the work proposed.

Taking the matter of the selection of sand alone, an illustration of the poor quality that is frequently used in practice is found in the tests in the laboratory of one of the members of the committee. Out of 37 samples of sand from different parts of the country made into 1:3 mortar, 12 were equal to or greater in strength than similar mortar of standard Ottawa sand; 5 were between 90 and 100 per cent. of standard sand; 6 were between 80 and 90 per cent.; 4 were between 70 and 80 per cent.; 6 were between 60 and 70 per cent.; 1 between 50 and 60 per cent.; 2 between 40 and 50 per cent.; and 1 between 30 and 40 per cent. Such results as these indicate the absolute necessity for always testing sand that is used in concrete. For large and important structures, such as dams, tunnels, aqueducts, buildings, and other reinforced concrete work, not only preliminary tests should be made, but frequent tests at stated intervals to avoid the danger of inequalities in the supply.

Tests of Materials for Acceptance.—The cement shall meet the requirements of the standard specifications for Portland cement of the American Society for testing materials and adopted by this association. (Standard No. 1).

Fine Aggregate.—Sand or other fine aggregate should always be tested. In ordinary cases where special characteristics are not required, the test for acceptance is the determination of the strength of mortar made up with the cement and fine aggregate to be used on the work in comparison with the strength of identical specimens made with standard sand. The results of this test also are an aid to the selection of the proportions which should be adopted.

Compression tests of mortar are the most reliable, but tensile tests may be employed when a compression machine is not available.

Selection of Sample.—Take an average sample aggregating not less than 20 pounds. Ship in strong box or bag or barrel, preferably water tight, so that laboratory will receive material in its natural condition. Ship in a separate package from the cement.

Quartering.—Unless grains are of uniform size, separate from the large sample the quantity required for the test by quartering or other similar means.

Making Test Pieces.—Mould a large enough quantity so that there will be at least 4 test pieces each to test at 72 hours, 7 days, and 28 days, in proportions 1 part cement to 3 parts sand by dry weight. Bank sand should not be dried, since drying may affect the quality, but the percentage of moisture should be determined by test on another sample, and corrected for in making the weights. The consistency should be the same as that required for standard sand mortar. From 10 to 40 per cent. more water may be required for bank sands or artificial aggregates than for standard Ottawa sand to produce the same consistency.

Similar test pieces of the same cement mixed at the same time under the same conditions should be made with standard Ottawa sand in the same proportions.

All temperatures of mixing and storage should be maintained at 70° F. During the first 24 hours the test pieces should be stored in moist air and the remainder of the period in water.

The 72-hour test is the most severe and sand failing to attain the requirement at this age frequently reaches it at 7 or 28 days and can be accepted. If, however, the 72-hour briquets break in the clips of the machine or if the test pieces at this age show very low strength, say 25 per cent. or below, of the strength of standard sand mortar, the sand should be considered dangerous to use on any important work of construction.

Requirements for Strength.—The aim in concrete construction should be to obtain a sand which produces a 1:3 mortar equal in strength to a similar mortar of standard Ottawa sand. Sands producing mortars having a strength of less than 70 per cent. of standard sand mortar should be rejected.

Between these two limits the variations in strength should be taken into account in fixing the proportions of the mortar or concrete.

Other Tests.—For work requiring special characteristics, the fine aggregate must be accepted not merely on passing the tests for strength, but other tests, such as the test for permeability, the effect of different brands of cement, the effect of frost action and the effect of fire. Characteristics of yield, density, chemical composition, granulometric composition, and amount of organic matter, are frequently required.

Coarse Aggregates.—It is recommended that the quality of the coarse aggregate be determined from the preliminary tests of concrete made with the materials and in the proportions designed to be used in the work. Government tests made at the Structural Materials Laboratory in St. Louis under the direction of Mr. Richard L. Humphrey, clearly show that the hardness of the particles of coarse aggregate appreciably affect the strength of the aggregate, so that greater stresses may be used in concrete when the stone is hard than when it is soft. In certain cases the chemical composition of the coarse aggregate may affect the strength and durability of the concrete.

Tests for Quality of Fine Aggregate.—In addition to the tests for acceptance which have been discussed in the preceding paragraphs, many aggregates require special tests. Furthermore, various laboratories have adopted different classes of tests to use with aggregates which come to them for examination. This can be discussed best by a consideration of the practice in different laboratories.

During the past year this committee has been in communication with all of the laboratories of which they were able to learn, in an effort to gather as complete data as possible relative to the various tests for a sand now in use. Each laboratory was requested to furnish a complete description of their methods of testing sands—in most cases such descriptions were freely furnished. In all, 28 laboratories were communicated with and replies were received from 24; of these, 15 gave more or less complete descriptions of their tests.

The data in these replies were tabulated and listed and gave some very interesting information. It was found that some 26 different steps are taken in these laboratories for the determination of the suitability of a sand for use in concrete or mortar.

Listed and briefly described, these steps are as follows:—

1. **Examination of Deposit** to determine its uniformity, stratification, extent, overburden, methods of stripping, handling, screening, washing, etc.

2. **Preparation of Sample** to eliminate stones, water, silt, and to insure its being representative of the bank or the quantity from which it was taken.

3. **Tensile Test of Mortar** to determine the strength of known mixtures of the sand and Portland cement at various ages and to compare this strength with that of standard Ottawa sand.

4. **Compressive Test of Mortar** to determine the strength of known mixtures of the sand and Portland cement at various ages and to ascertain what mixture is necessary to produce a required strength, or impermeability.

5. **Compressive Test of Concrete** to determine the strength of known mixtures of the sand and a coarse aggregate and Portland cement at various ages and to ascertain what mixture is necessary to produce a required strength or impermeability. In the case of bank gravel or crushed stone which is not to be screened and reproportioned, this test is used instead of No. 4 above.

6. **Percentage of Moisture** is determined in order to allow for the water contained in the sand in proportioning mixtures, computing freight rates, etc.

7. **Percentage of Voids** is determined:

(a) By determining the specific gravity of the solid particles and weighing a known volume of the sand and computing therefrom the percentage of voids.

(b) By filling the voids in a known volume of sand with a measured amount of a liquid.*

8. **Yield, or Volume of Mixtures** is determined by adding a known quantity of cement to a known quantity of the sand, wetting the mixture and noting the increase in the volume of the sand. This is repeated with various proportions of cement and sand to ascertain the amount of cement required to fill the voids in the sand.

9. **Density of Mortar and Concrete** is determined for various mixtures of cement and sand and of cement, sand and stone to ascertain that mixture which gives a material of the greatest weight per unit of volume.

10. **Specific Gravity of Solid Particles** is determined by three different methods:

(a) By the specific gravity apparatus such as the Jackson flask.

(b) By pouring a known weight of sand into a known volume of water and noting increase of volume of liquid.

(c) For coarse aggregate by suspending pieces by a thread on chemical scales and noting weight in air and weight when hanging in a jar of water.

11. **Specific Gravity of Sand,** including voids, is determined by weighing a known volume of the sand exclusive of moisture and computing the specific gravity from the known weight of the same volume of water. Having determined the specific gravity of the solid particles (Test 10) and also that the sand (including voids) the per cent. of voids in the sand may be calculated.

12. **Weight per Cubic Foot** is determined by weighing a known volume of the sand. This test is very closely related to Test 11.

13. **Granulometric Analysis or Mechanical Analysis** is made by passing a known weight of the sand through a series of sieves of various sizes and noting the amount retained on each sieve and the amount passing the finest one. This test shows the distribution of the particles from fine to coarse.

14. **Uniformity Coefficient** is determined from a curve plotted from the granulometric analysis by dividing the diameter of the particles at the point where the curve crosses the 60 per cent. ordinate by the diameter of the particles at the point where the curve crosses the 10 per cent. ordinate.

15. **Wet Screening** of a sand on the 100 and 200 mesh sieves shows the amount of fine material which can be washed from the sand and which in the case of dry screening in Test 13 often adheres to the larger particles and so leads to uncertain results.

16. **Silt Suspended in Water** is determined by agitating a quantity of the sand with a large excess of water in a tall cylindrical glass vessel and noting the amount of silt which becomes suspended on the water and later settles down on the top of the sand.

17. **Silt Washed Out** is found by agitating a known quantity of the sand in water, allowing the coarse par-

ticles to settle and decanting or syphoning off the muddy water from the top. This operation is repeated until clear water is obtained. The amount of silt washed out is determined after evaporating the water.

18. **Loss on Ignition** is determined by heating to a red heat a weighed quantity of the dried sand and again weighing after cooling. This test is best performed only on the silt washed from a quantity of sand, as the silt usually contains the injurious organic constituents of the sand.

19. **Organic Matter** is sometimes determined after the methods employed by the agricultural chemists.

20. **Chemical Analysis** is made to determine the character of the sand grains. Only a few of the most common rock constituents are usually determined quantitatively, for the purpose of judging of the strength and durability of concrete made from the sand. A high silica content is usually desired.

21. **Microscopical Examination** is made to ascertain the approximate size of the grains, their shape, character of surface and to detect the presence of objectionable material or foreign matter such as mica or small roots or a coating on the grains.

22. **Absorption of Mortar and Concrete** made from the sand mixed in varying proportions with cement or cement and stone is determined to ascertain its suitability and the proper proportions for the production of a product having a minimum of absorption.

23. **Permeability of Mortar and Concrete** made from the sand is sometimes determined for various proportions of the constituents in order to determine mixtures for the production of an impermeable mortar or concrete.

24. **Effect of Different Cements** on some sands is quite variable and tests are sometimes made to determine with which of several available cements the sand will give best results.

25. **Freezing** during the setting time has a more injurious effect on mortar and concrete made with some sands than those made by others, and tests are made to determine the extent to which the sand is affected by freezing.

26. **Fire** has a more disastrous effect on some sands when used in mortar or concrete than it has upon others and a heat test is made to show the ability of the sand to resist fire. No two of the many laboratories engaged in this work have used the same tests, and scarcely two of them carry out their tests in exactly the same manner, so that at present it is difficult or impossible to accurately compare the results obtained in one laboratory with those obtained in another.

Examination of the list shows that the popular tests for sand at the present time are granulometric analysis, tensile tests of mortar, and percentage of voids. Of these only one, the tensile test of mortar, belongs properly in the classification of tests for acceptance as discussed in preceding paragraphs of the report.

The problem before the engineer who is interested in proper methods of testing materials is to select and standardize such tests as will give the necessary data which will determine whether or not the sand is suitable for a particular use and, if suitable, in what proportions it should be used to produce desired qualities in the resulting mortar or concrete.

---

*This method as usually practised is very inexact on account of the air entrained.

WOOD PIPE LINE CONSTRUCTION IN THE WEST

The question of water supply is one of the most difficult problems with which the western railroads have to contend. Each year large sums of money have been expended—and not always successfully—in an effort to obtain a good supply. In the prairie sections water is sometimes very scarce and has to be piped many miles from the source of supply to the point where it is to be used; and in many cases the water is unfit for boiler use in the raw state and has to be treated by some softening process. Even after a seemingly good supply has been located it is hard to judge as to whether it will be capable of producing enough water for the purposes required. There are a few plants (generally of the well type) which have turned out decided failures, having been pumped dry in a short time. This state of uncertainty will, of course, disappear when we have more extensive data on the streams in the west—such as the hydrographic survey is preparing from observations of its engineers. As it is now, the water supply engineer has to make many assumptions and therefore one should not judge him too harshly if he makes an error.

The engineering department of the Canadian Pacific Railway Company has been making observations and collecting data respecting certain possible water supplies with a view to their usefulness at a future date, when new lines and heavier traffic will demand more water. One of these points is Rock Lake, which is situated nine miles northwest of Stoughton, the junction of the Regina and Weyburn subdivisions. Water was required here on account of the heavy freight traffic which is being diverted from the main line. Heretofore the tank at Stoughton had been filled with water from Kisbey, a station eight miles south of Stoughton, necessitating the hauling of water cars every day, and making it a very expensive supply. The water of Rock Lake is quite suitable in the raw state for boiler purposes.

Rock Lake is a body of water with an area of 360 acres. It is situated at the junction point of several coulees amid rolling land, and has no surface outlet or inlet, the water being gathered entirely from underground springs and from surface drainage in the wet season. The shore and bottom of the lake are of quartz sand and boulders. The country roundabout is clay loam on the surface, while in the immediate vicinity of the lake one runs into quicksand 6 feet from the surface, which changes to a mixture of sand and clay toward the higher land.

The pipe line was located along a road allowance from the lake to the railway track, and was then turned into the right-of-way where it paralleled the centre line direct to the tank, totalling 6½ miles on the road allowance and 2½ miles on the right-of-way.

The plant at the lake consists of pumphouse and cottage for pumpman, both being frame buildings on concrete foundations. A well 16 feet deep and 16 feet in diameter was sunk and connected to the lake by an 8-inch iron pipe 190 feet long, the water flowing in by gravity. The water is pumped from the well through an 8-inch cast iron suction pipe to the pump, and discharged into an 8-inch wooden pipe, wire-wrapped, pitch coated, and tested for 350 feet of head pressure. The wooden pipe line was laid in an 8-foot ditch for protection from frost. In short potholes and places where it was impossible to get a good joint by following the ground line, the pipe was put down as far as possible and extra material placed on top after backfilling was completed. Air valves were

located on all summits, there being 9 of them on the entire line. There are 4 gate valves at approximately uniform distances, but located in sags wherever possible. There is also a gate valve in the cast iron pipe on the intake side.

The buildings, intake works, manholes, etc., for the line were built by the bridge and building department of the Canadian Pacific Railway, under the superintendence of Geo. Armstrong, bridge and building master. The contract for ditching, laying and backfilling was awarded to the J. A. Broley Co., of Fernie, B.C. The contractor started work on the ditch close to Rock Lake and worked toward town. Harvesters' cabooses, drawn by horses, were used as cook and sleeping quarters. An Austin drainage excavator fitted with caterpillars was used for ditching. At the start it was not very successful, owing to the presence of quicksand, which filled in before the pipe could be placed. As a result it was decided to leave all bad places to be finished by hand. When the machine reached higher ground it made better progress, although a great many delays were caused by the bucket chains breaking by being wedged against stones, which were quite numerous in places. As the pipe was so easily laid in the dry places it was often put in during overtime after supper, the men working on the wet spots during the regular day. When the machine was digging in sandy soil which was not too closely packed it could make 800 feet a day, but sometimes breakdowns to machinery from the above unavoidable causes would reduce this to one-half the amount.

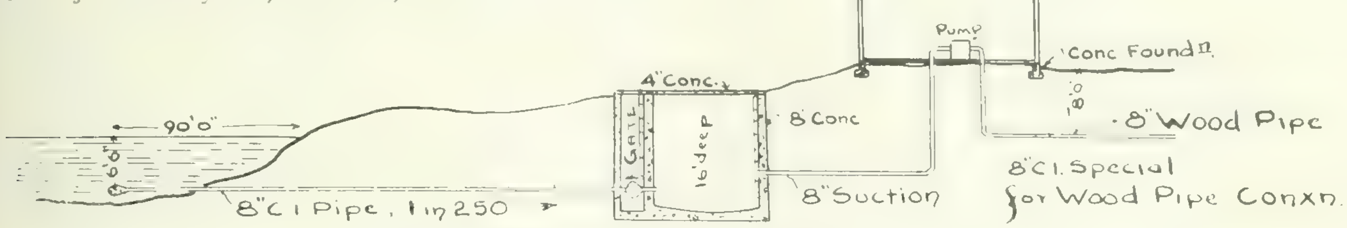

Fig. 1.—Section Showing General Arrangement of Plant and Piping.

Fig. 2.—Rock Lake and C.P.R. Pumping Plant.

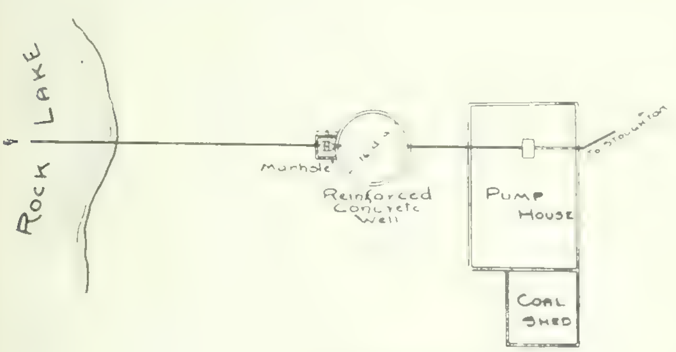

Fig. 3.—Plan of Intake and Pumping Plant, Rock Lake.

The pipe was prepared for driving by filing the spigot end so as to allow the pipe to enter the sleeve easily. This filing also prevented the end of the pipe from splintering, and the fibres from turning back and causing leaks. After filing, a little gear grease was applied to the spigot to aid in driving; the sleeve end of the pipe was also carefully inspected to see that no lumps of pitch adhered to the wood, as this is also a possible source of leakage.

The longest stretch of pipe laid in one day was 1,629 feet. The number of men actually engaged in driving was as follows: 1 foreman; 1 man filing and greasing spigots of pipe (part of time and tamping part of time); 2 men on surface dropping in pipe (sometimes having to carry pipe for short distances); and 3 men in the ditch driving pipe and removing material left by machine. The men in the ditch also attended to the tamping when held up for pipe or other reasons.

The pipe was driven by a dolly made of a tamarac tie about 5 feet long and ironed on each end to prevent brooming. It was suspended from a chain attached to a plank across the ditch. The pipe was protected by a plug of fir inserted in the sleeve while driving.

Fig. 4.—Pipe Line Construction Through Water Covered Land.

The wet places were dug by hand, sheet piling being used to hold the bank up. Several methods were used by different foremen, but the best results were obtained by digging holes from 8 to 12 feet long according to the conditions, leaving a space of 2 or 3 feet between. This space was afterwards tunnelled out. By this method less sheet piling was required and as the pipe was laid, the water was dammed in the tunnel reducing pumping to a great extent; generally an ordinary diaphragm pump being all that was necessary—although larger pumps had to be used in several cases.

Where sloughs with water on the surface were encountered the method of procedure was to build a puddle dam about 6 feet on each side of the centre line, and then to pump out the space between, by gasoline pumps. In

one case a 6-inch centrifugal pump was necessary as the quantity of water was too great to be removed by slower methods. After the water was removed from the surface, the method of excavation above described was feasible.

Some difficulty was experienced during wet weather on account of the pipe being raised by the buoyant force of the water, which filled the ditch in low-lying parts. In some cases the pipe dropped to place on the removal of the water, but where sand had worked in under the pipe, it was necessary to remove the pipe, and clean out the ditch, afterwards relaying the pipe. This trouble, however, would not have occurred if the backfilling had been done regularly, and kept close to the pipe-laying, the work being in the hands of a subcontractor. A mormon scraper was used for backfilling the ditch, one team and 2 men being able to do 700 feet of dry work or 200 to 300 feet of wet backfill in a day.

WATER IN MACADAM ROAD CONSTRUCTION.

An interesting and instructive paper on the subject of the part played by water in macadam road construction was read on November 24th, 1913, by W. G. Fearnsides, M.A., F.G.S., fellow of Sidney Sussex College, Cambridge, and Sorby professor of geology in the University of Sheffield, before the British Surveyors' Institution. Professor Fearnsides endeavored to show that though the chemical action of water upon materials in roads is small compared with the rate of mechanical wear, yet water in excess is most generally responsible for the automatic disintegration and decay of roads, and also care should be exercised in the choice of materials to be buried in road foundations so as to use those less rapidly affected by the solvent action of water. The lecturer also dwelt upon the fact that the power of water to bind is an effect of surface tension; and for maximum strength and efficiency it is important that the proportion of water be kept at the optimum; "as dry as it can be drained" being the first approximation to the optimum for most water-bound road materials. He did not deal further with the subject, but concentrated his remarks upon water as a disintegrator and as a binder, and more particularly in the road crust; though a small part of his paper, he devoted to a consideration of the ground formations on which roads are built. It has been shown that in some instances the lecturer has shown the disadvantages without noting the advantages of the various effects which water has upon materials discussed; i.e., the effect of water in dissolving the felspar of certain stones; the effect of water on rocks containing iron in the ferrous state; the effect of water on limestone road crusts; and the effect of chemical action upon the foundation course or bottoming of the road. However, the paper has been described as one which "gives the road-making world plenty of food for thought," and his conclusion that for each and every road aggregate there is a characteristic optimum proportion of water, which, if he is to produce the most efficient service for the road user, the roadmaker cannot afford to disregard.

The gist of Professor Fearnsides' paper is given in the following detailed account:—

Geologists and makers of roads have long found common interests in the study of stones, both as road metal and in the bed rock on which the roads are built. The speaker wished to direct attention to the special part played by water as an essential constituent of all road constructions, and as the agent which, present in excess, is most generally responsible for their automatic disintegration and decay.

Water, strangely useful and commonplace in many of its properties, is in others strangely unusual and peculiar, and after all these years of progress remains in many essentials an enigma to the scientist. To the chemist the most striking property of water is its power to dissolve a little of almost everything, and that with many substances it combines to form hydrates. To the physicist perhaps the most remarkable properties are the high boiling point, the vast change of density when water evaporates, and, related to this, the great skin strength of surface energy possessed by liquid water. Other important properties are the high values of the latent heat constants both between ice and water and for water which is evaporated. The circumstance that water expands by one-eleventh of its volume when it becomes ice is almost unique, and, coupled with the other circumstance that the solidification temperature of water lies within the normal range of diurnal or seasonal variations of atmospheric temperature, leads to those phenomena which collectively we describe as frost.

Considering these properties of water from the point of view of the water in roads, water left to itself will, in time, dissolve a little of almost any road material. Natural waters have at one time fallen as rain, and in their passage through the atmosphere have taken up carbonic acid and oxygen from the air. Water as a solvent cleans the surfaces of the mineral particles which aggregated form the road stones, and brings the carbonated and oxygenated water into chemical contact with the bare surface. If all the mineral particles of the stones are of such composition that none of them react with the aerated waters, all is well, and neither rain nor water carts can work chemical damage to the road. Usually this is not the case, and, except in the case of flints, and perhaps some quartzites, there is reaction between atmospheric waters and some or other of the mineral constituents of the road stone, which in time leads to the disintegration of the stone.

Any rock which contains felspar—and the best road stones, granites, syenites, diorites, basalts and the like consist largely of felspar—will have the felspar gradually attacked, and the less silicious the felspar the more soluble does it prove. Any rock which contains a mineral rich in iron in the unoxidised—that is, in the ferrous—state will have that mineral rusted as well as partially dissolved. Any rock which has a mineral rich in lime will have that lime mineral transformed to calcium carbonate, which, in continuation of the same process, will surely be dissolved. Any sulphide mineral will in time be in part oxidized to sulphate with the production of some free sulphuric acid, a substance which may be trusted to disturb the equilibrium of its surroundings, and greatly to further the disintegrating process.

Chemical Disintegration.

The rate at which stones in a road crust suffer chemical disintegration is not, in general, great as compared with the rate of mechanical abrasion by traffic; but in the under or foundation layer, where "out of sight is out of mind," and the stones are left to stew in water—sometimes percolating, sometimes stagnant—for whole seasons together, chemical solution is the process which counts. On ordinary road stones solvent action is most destructive and rapid when it attacks carbonate of lime present as a cement holding other

and less soluble mineral grains together. The hard cement stones of the lias and the oolite clay districts of the south-eastern Midlands often go to pieces from this cause. Corallian calcareous grits of Yorkshire and Dorset, upper and lower greensand of Devonshire and the Weald, and even the famous Kentish rag in its less compact condition, should be protected from the solvent action of water, and when buried are never free from suspicion. Bastard limestones, much used for second-class roads in the Pennine district, as well as in parts of Devonshire, Shropshire and North Wales, also suffer solution changes, but with the increase in the percentage of lime carbonate the dissolving waters become saturated at the surface of the stones, and the danger of actual disintegration by partial solution is reduced.

Igneous rocks, when compact and fresh, are attacked so slowly that through the space of one man's life they may be considered as immune. If already porous and partly weathered in the quarry they generally contain some carbonate of lime, and may quickly go to pieces when subjected to continuous soaking within the road. In certain regions, such as the English Lake District, the Breidden District, the mountain district of North Wales (including a certain section—now proverbial—of the Holyhead road), it often happens that this type of altered igneous rock is the only rock which the casual laborer has skill enough to quarry, and though excellent material is available at no great distance, these, and these only, are used upon the roads.

Of all road materials now in common use, those that are most rapidly affected by the solvent action of water are the slags. Slags upon a road crust can be observed, and though after every shower the characteristic aroma of their reaction with water can be smelt, it is a matter for argument whether their cheapness does not compensate for the rapidity with which they disintegrate, whether under the action of atmospheric water or under traffic. Placed beneath the crust to act as a go-between and weight distributor from the road surface to the foundations, no slag is ever safe, and numerous are the cases known to me where estate roads made up with slags and dressed with satisfactory coatings of the best macadam developed crop after crop of potholes by reason of the spasmodic and irregular, sudden or gradual disintegration of odd pieces of the slag which lie invisible and soaking continuously in the ground waters below.

Physical Characteristics of Water in a Road.

The speaker considered first the property by which water wets the solids with which it comes in contact. The primitive concept of a liquid as a fluid which wets things is widespread. Certainly the liquid water does wet—that is, spreads as a film over the surface of most common solids—but it is not difficult to mention a score of liquids which, when sprinkled upon the surface of common solids, refuse to wet them, and which, instead, curl up into globules and remain as scattered drops upon the surface. This difference of behaviour is due to intrinsic differences between two classes of liquids, and the physical property which controls it can be numerically evaluated and tabulated, and is known under the name of "surface energy" or "surface tension."

For a liquid to wet a solid there must be a degradation of energy when the two surface films (solid-liquid and liquid-air) are substituted for the one surface film (solid-air). When, on the other hand, a liquid refuses to wet a solid, there is indication that the energy value of the solid-liquid plus liquid-air surfaces would be greater than the energy value of the existing single surface film of solid air.

Glass is a solid readily wetted by water. When two glass plates are brought close together with one or more drops of water between, the two plates stick together, and the force required to drag them apart is considerable. Professor Fearnsides did not attempt the mathematical analysis of the manner in which the force which resists the parting of the plates is developed—it is discussed in Poynting and Thomson's "Properties of Matter"—but merely said that it was determined by (1) the surface tension—i.e., the skin strength of the water; (2) the curved water-air surface, which, by reason of its surface tension, the water in the narrow space between the plates develops, and (3) the difference of pressure inside and outside the water film which the curved skin of the water renders possible and necessary. The net result is that two glass plates with a water film between require a force almost equal to the pressure of the atmosphere (about 15 lbs. to the square inch) to begin to separate them.

This experiment may be repeated using plates of mica instead of glass, and find that the force required to drag apart the wet mica plates is slightly greater than in the case of glass. A whole series of damp mica plates may be piled together and it will be found that in order to break the column of the mica pile force almost as great must be employed. In order to obtain the maximum tensile strength of piled plates it is essential that the plates should be flat-sided and in parallel position. Plates with water drops between, and kept from parallelism by a match stalk wedged in at one edge, are not difficult to separate. To separate curved surfaces of glass with water drops between requires some expenditure of energy, but the plates come apart quite easily.

Behaviour of Water-bound Materials.

The experiments just indicated exactly reproduce the behaviour of water-bound materials in a road. The road materials which, bound with water, are most strong, are those which break into pieces with flat faces, and whose constituent minerals break with a cleavage into flat-faced grains, and are readily wetted by water. Derbyshire limestone, for instance, breaks into flat-sided tetrahedral pieces which will pack, and its powder consists of the flat-faced rhombohedra of calcite. With the right amount of water Derbyshire limestone binds magnificently.

Our experiment was made with mica. Sorby, Hutchins and others have proved that most clays consist of minute flakes of mica. Clay makes excellent bricks, which, when dried, are strong enough to stand one upon another to the full height of the kilns even before they are burnt. This strength is the strength of the water films between neighboring mica plates, strength exactly analogous to the strength of water-bound macadam.

If the experimental pile of mica plates, or the brick dried ready for the kiln, be dropped into water, the air which with water shares the narrow places between the mica flakes is displaced, and the strength of the aggregate so diminished that the mica pile becomes "weak as water," and the brick "falls" to muddy clay like, but more muddy than, the clay from which it was made.

Tensile and Crushing Strength.

The professor mentioned this behaviour of bricks to suggest that, by making briquettes of crushed road

stone, an excellent indication of the binding power of the road stone can be quickly obtained.

The speaker said that he had tested the strength of briquettes made from road stones which have been collected at various places, and had found that in general those rocks which have the lowest silica percentage when briquetted give the greatest tensile and crushing strength. With certain rocks, such as flint, he had failed to make briquettes except with the addition of a quantity of clay binder, and had found that when powdered flint is added to clay the strength of the briquette is that of the clay only. He had made briquettes from fresh road stone (Clee Hill dolerite) freshly powdered by himself, and from road scrapings taken from a water-bound road of Clee Hill stone which was well-nigh worn out, and had found that the strength of the briquette of the road scrapings is less than one-quarter that of the freshly crushed rock. He had also tried to make briquettes of road sweepings from a tar-bound road of Clee Hill stone, and was rather astonished to find that these sweepings failed to bind. Now he recognizes that spent tar and pitch belong to the class of solids which water does not wet, and from the similarity of the behaviour of powdered flint groups raw flint with these as the one common rock which water does not wet, and which, therefore, it cannot bind.

Thus far has been considered the strength of a water-bound aggregate as an absolute property which is determined by the form and composition of the particles bound. As a matter of fact, with one and the same aggregate of rock fragments mingled with different proportions of water, the strength (that is, the stress which the aggregate can accept without coming asunder) varies enormously. It is recognized that stone dust when dry has no strength, and that when fully wetter to the state of mud its strength similarly is nil. In the intermediate damp stages the strength is considerable and characteristic. This may be conveniently expressed in the form of a curve, which passes through the origin, rises very rapidly to a definite maximum, and then falls away again.

The most important characteristics of the curve are (1) the height of the maximum (i.e., the maximum strength); (2) the distance from the origin (i.e., the percentage of water) at which the maximum occurs. Powdered mica gives a high maximum very close to the origin; powdered quartz a low maximum rather far away. This curve should be determined experimentally for each road stone used in large quantity. Professor Fearnsides inferred that rocks whose strength attains a maximum with little water are suitable for use in dry climates, while those in which the maximum is far from the origin are more suited to the damp atmosphere and frequent showers of the hills; and he believed that experience on the road confirms this inference. Quartzite and flint roads are undoubtedly at their best after rain or in damp weather, at which times water-bound limestone roads become almost impassable.

The lecturer said that he had labored these details of the origin of the strength of water-bound aggregates at some length, because, both from observation and from experiment, he concludes that it is the statical strength of the road crust that determines its resistance to wear. If the passing loads distribute stresses which can be taken up by elastic deformation, there is no grinding of stone on stone within the road crust, and the work done in deformation is dissipated without altering the conformation of the road aggregate. At their best most roads are strong enough thus to carry their loads without serious internal wear, but who, in wet weather, or after a frost, has not heard the "scrunch, scrunch" of internal grinding of the stones beneath the wheels of a wagon as it passes along a road? The importance therefore of maintaining the quantity of water in a road at a proportion not far different from that required for the condition of maximum strength is considerable. To this proportion the speaker hereafter refers as the "optimum."

Potholes.

The subject of potholes is closely related. Potholes are areas where, by faulty or non-homogeneous construction of the sub-crust, or by some other cause, the road crust is maintained or remains damp for periods longer than in the areas adjoining. Hence when, after a wetting, the average of the road in drying passes from a condition of weakness to a condition of comparative strength, the place of the pothole remains weak, and the passing traffic continues to grind stone upon stone within the crust at times when over the rest of the road this type of wear has ceased.

Two years ago the professor said he came across an old road-mender on the Cambridge-London main road at his wits' end to cure a crop of potholes in front of the entrance to a patron's estate. The subsoil at the place is coarse gravel, and the road has been mended several times without remaking. It seemed, therefore, that this was a case of water standing in puddles in the sub-crust. He therefore persuaded the old man to drive a bar or spike down to the gravel in the midst of each of his potholes, and passing the place this summer rejoiced to be informed, and to see for himself, that, though the strip of road has not yet been redressed, the potholes are no more.

Allowing that explanation of potholes is correct, it follows that a uniform and complete sub-crust drainage will entirely prevent them, and that there can be no cure for existing potholes as long as water in the sub-crust distributes itself irregularly. It also follows that there can be no surer method of securing the development of potholes than to put upon a wornout and insufficiently scarified road a thin dressing of new macadam. Road surfaces, by the crushing of the surface stones, become fairly impervious, and each depression or rut which is covered by the new coating is a cup to hold water longer than does the rest of the road, and hence the over-rapid wear of the road crust above it is assured. The distribution of sub-crust water-pockets and their resulting potholes is a long and complex subject, and with the comment that over-watering in the dusty season is one of the most effective methods of keeping the water-pockets supplied with water, the speaker proceeded to other matters.

"Site-Rocks."

Not only does water give strength to macadam, but it is water which holds together the particles of which the weaker of the road "site-rocks" (or ground foundations on which the roads are built) consist.

Site-rocks from the point of view of the road-maker may be divided into three classes:—

(1) Rocks which consist of compact pieces of hard material separated one from another by joints or open spaces which are wide enough to allow water to pass freely through them under gravity. These give no trouble to the road maker, and beyond the clearing away of irregularities and the removal of soil, the sites which they afford require no preparations for the road crust coating.

(2) Rocks without open joints, in which the constituent mineral particles are fairly large and the pores between them wide enough for water to filter slowly through. Road sites on these foundations are sufficiently well protected from the accumulation of excess of water by the provision of adequate lateral drains.

(3) Rocks fine-grained and argillaceous. These, the clay rocks, consist in large part of minute flakes of mica, and owe such strength as they possess to the air-water films which bind them. These have mostly originated as mud upon the sea bottom, but as found in mines and deep cuttings, by reason of the pressure of overlying strata, they have lost much of their water and become strong. Exposed to the atmosphere for long periods, in the soil, or kept in contact with water, they "fall" to slime or incoherent mud, and while they are "falling" they develop the properties of a viscous fluid. Kept dry they retain their strength, and some of them if laid bare in dry weather may increase in strength. By reason of the fineness of their grain they are well-nigh impervious to the percolation of water, and any water which comes upon them either is absorbed to the diminution of the strength of the clay it wets, or, diverted by the impervious surface, flows away under gravity. Though the process of absorption is more or less slow, it is continuous and sure, and whenever a load is borne upon a surface of clay which is kept constantly wetted there must eventually come a collapse.

Landslips generally occur on hillsides where a clay foundation supports more massive rock, and, becoming wetted by trickling water, can withstand their load no longer. Road sites of argillaceous rock must therefore be guarded with special care from the action of water. Lateral drains are the best preventive against the water from outside, but the American method of shaping clay road sites with a plough and compacting them to a camber with a steam roller before making up the road at all, is one which commends itself to the geologist as a means of conducting away the water which enters from above. Upon the cambered clay surface sufficient of a coarse-textured make-up layer must be provided to distribute the pressure of traffic over a wide base, and to act as an open drain to the water which sipes in through the road-crust.

Many of the worst roads are along outcrops where pervious and impervious rocks meet, and it would be well if those whose profession it is to plan new roads could avoid such localities. Springs occur at these places, some of them with continuous flow, others rising intermittently as bournes only when the level of ground water in the porous strata comes to the surface; and if here the road be founded upon a clay rock which loses its strength by wetting, trouble must ensue. In any case the access of ground water to the road crust cannot do other than impair the wearing power of the road.

Variation in the Properties of Water.

The lecturer noted first the changes of vapour pressure. By reason of the changes in the maximum pressure which water vapour can sustain, there is the phenomena of dew and hoar-frost, and, for the matter of that, all the phenomena which accompany and control the humidity of the atmosphere and the precipitation of rain. These, and the influence they exert on the production and laying of surface dust, so force themselves on the notice of road makers that they are always watched for, and as far as possible kept in check by the surveyor's arrangements for the disposal of excess, and for the supplementing of any deficiency of water.

Before leaving this subject he drew attention to the influence which the surface form of the water has upon the temperature of saturation. This influence has been well studied in the case of rain-drops, but seems to have passed unnoticed in the case of the water surfaces among the crannies of stones, where films of water are giving strength to clay or binding macadam together. The dew-point for convex surfaces is lower than that for flat ones, and, again, the dew-point for concave surfaces is correspondingly high, rising the more in proportion as the curvature (that is, the narrowness of the cranny) is increased. Who has not noticed that the large pebbles on a beach dry more quickly than does the sand? Who does not know that a sandy soil remains damp less long than a field of clay? It is all a matter of curvature of the water surfaces. For the same reason a new-coated road, in which all the surface particles are still large, remains unaffected by dew or incipient fog long after an old and well-trafficked road has been reduced to a condition ideal for a skid.

Flint, as has been already seen, behaves as a material which water does not wet, and between flint fragments the water stands in globules. Flint roads, therefore, do not become slimy under the action of dew, and, despite its excellence as a "puncture mixture," there is no more efficient material than flint grit for sprinkling on wet and dirty roads to reduce the slipperiness.

Sub-Crust Dew.

There remains also the important question of sub-crust dew, which "droppeth" not "as the gentle rain from heaven," but rises or transpires from "the waters under the earth" whenever the outside atmospheric temperature falls below that of the rocks within. Like normal dew, when it arrives at the cooled surface, it precipitates itself upon the water films, and, increasing the proportion of the water beyond the optimum, reduces and perhaps altogether destroys the strength of the road crust. Each autumn we see water-bound roads which have been strong all the summer going to pieces from this cause; they seem as if they will never dry. Roads dry and good before a frost are notably wet and unpleasant when the thaw comes, and this whether or not rain has fallen in the interval. Tar-painted and other roads with waterproofed surfaces are just as bad as unpainted ones with respect to this, and, indeed, the over-wetting of well-drained water-bound roads after a frost is only rendered possible by the sealing of the outward ends of the air passage by ice, a sealing which by design is already accomplished in the process of waterproof painting. As to means of preventing the ravages of sub-crust dew, Professor Fearnsides had nothing to suggest; but said that just in proportion as the source of the warm underground water is easy or difficult of access, so is the process of surface condensation immediate or delayed.

Efficient sub-crust drainage is therefore important, not only for keeping up the general strength of the road crust, but also because it delays the arrival of the winter's damp, and so secures that the proportion of days when the road's optimum strength is reduced is kept as low as possible.

The Phenomena of Frost.

Frost swells the water which is contained in narrow places, and whether the narrow places are cracks within the stones or crannies in which the water is at work binding the stones together the water must expand,

and the cracks must open. In well-drained roads in which the water content does not far exceed the optimum, there is generally ample room for the ice to expand between the stones. Where, however, by the choking of the sub-crust drainage, or by continued condensation of sub-crust dew, the air spaces in the road are more completely filled with water, the frozen crust has to expand, and expanding detaches itself from the rest of the road, and rises as the cavernous blisters which we know so well. Then comes the thaw, and the bursting, disintegrating and disarranging work done by frost becomes evident; but much of the winter damage ascribed to frost is really the work of sub-crust dew, and can be minimized by the provision of a proper porous make-up layer in which water does not accumulate.

The discovery of Macadam was that road stones so broken that they would pack are held together by films of water. Makers of modern roads follow Macadam in preparing road metal aggregates by breaking stones to a more or less uniform mesh, but with the coming of motor traffic and its attendant dust they have had to find binders stronger than water, in order to hold their stones together under the increased stress of traffic. Except for raw flint, the road materials known to Macadam were all substances which water wets with avidity, but in these modern days this is altered, and materials which water cannot bind have now to be reckoned with upon our roads.

When carbonaceous binders are new laid they are viscous and resilient, and yield under stress without breaking; but when, with lapse of time, by differential evaporation of the tempering oil they become hard, they break under the hoof or wheel, and make a mud, or rather an emulsion, which is devoid of strength. When looked at with a lens, spent tar or pitch which has been scraped from a wet road and laid on blotting paper, shows the water curled up as globules between the pitchy splinters, and without raising the temperature all my attempts to make it into briquettes have resulted in failure. Water will not bind it, and if a proportion of it be mingled with powdered road stone the strength of the water-bound mixture is diminished as the proportion of the powdered pitch increases. Users of cars have learned to respect the iniquities of the churned-up mud which in certain places accumulates on tar-painted or pitch-bound roads. Mud rich in animal or vegetable refuse has similar characters.

There is also another side to this question, and this involves the success or otherwise of these carbonaceous binders. Water does not wet the binder, but water does wet the stones, and if water has spread itself as a film over the surface of the stone the carbonaceous binder cannot "wet" the water, and therefore cannot get into contact with the stone. Even if by drying the water has been removed from the stone surface, it is likely to remain in the narrow cracks and capillaries, and when the carbonaceous binder spreads over and adheres to the general surface, it fails to make contact with the damper spots, and its hold upon the stone is incomplete.

The Road Board's Trials.

The speaker told how he had watched with interest the Road Board's trials along the Eltham-Sidcup road and elsewhere, and had visited the trial strips at a good many stages of their history, and has studied the interim reports. Were he to make a special report of his own he should say that the success of each individual strip has depended, and depended only, upon the hold which the binder has maintained upon the stones. Some of the strips are most certainly worn out, but in every case it has been the binding which has ceased to hold the stones, and not the stones which have collapsed within the binder. In these trials, and, indeed, elsewhere, the patent "Tarmac," made up of furnace slag (a road stone which, as a geologist, he could never place higher than third class), takes a high place, and he opines that the chief reason for its success is to be found in the circumstance that the slag, cooled directly from the state of fusion, can never have had any water spread or condensed upon its surface. Other successful aggregates are those in which the stones have been heated above the boiling point of water before they are mixed with the binder. By this heating the stones must of necessity be made dry, and hence, if the binder will spread upon them, a successful junction is assured. Next best are the processes by which boiling tar, pitch or bitumen is mingled with cold stones, but the removal of water by this means is never complete, and the method, as a rule, is not quite satisfactory.

The formula adopted by the British Cork Asphalt Company interests Professor Fearnsides. It excludes a certain quantity of Portland cement, and he was anxious to know why. It occurred to him that cement is an excellent dehydrating or drying agent, so he tried some experiments which lead him to believe that cement sprinkled over the surface of damp stones licks up the water, and makes it possible for tar or asphalt to spread over and make firm contact with the stones. About a year ago he wrote to one in authority suggesting that this method of chemical drying ought to be tried, but was given to understand that the cost would be prohibitive. Personally, he thinks otherwise, and is convinced that if those whose business it is to make tar or pitch macadam will dry their stones by mixing with them a little quicklime before the carbonaceous binder is added, the increased efficiency of contact between stones, the binder will more than repay the increase of cost.

Conclusions.

(1) The chemical action of water upon materials in roads is small as compared with the rate of mechanical wear, but care should be exercised in choosing materials which are to be buried in road foundations. Furnace slag for this purpose is not above suspicion.

(2) The power of water to bind is an effect of surface tension, and for maximum strength and efficiency it is important that the proportion of water should be kept at the optimum; "as dry as it can be drained" is the first approximation to the optimum for most water-bound road materials. Potholes grow by the wear of traffic at those places where by local water-pockets the proportion of water is kept above the optimum.

(3) Certain site-rocks, the argillaceous or clay rocks, owe their strength to water binding, and are subject to the same conditions of optimum water content. The importance of cambering and draining the site is, therefore, equal to that of arranging the configuration of the road surface.

(4) The effects of dew, more especially the dew which distils from below, are noteworthy, and in this, as in the question of the strength of the road, the importance of complete sub-crust drainage is to be emphasized.

(5) Water among solids which it does not wet acts as an insulator, and in the making of tar, pitch, asphalt or bitumen macadam should be rigorously eliminated

before stones and binder are brought together. The feasibility of chemical drying by adding to the partially dried stones a suitable proportion of quicklime or unslaked cement is suggested.

Summarily it is concluded that for each and every road aggregate there is a characteristic optimum proportion of water, which, for efficient service of road user, the road maker cannot afford to disregard.

COAST TO COAST.

Saskatoon, Sask.—The report for the light department for November showed that 143 new light services and nine new power services were installed, which is the largest increase shown in this department for some time.

Edmonton, Alta.—The street railway department reports a deficit of $13,000 for the month of November, 1913, as compared with a deficit of about $5,000 for the same month in 1912.

Souris, Man.—Mayor Dolmage formally opened the new light and power plant at Souris on December 20th in the presence of many of the citizens by throwing the switch that turned the current on to the standard lights on both sides of Crescent Avenue.

Edmonton, Alta.—After having reduced the cost of power to the electric light and street railway departments of the city, a sum equivalent to $6,601.80, during the month of November, the power house is still showing a net surplus for this month of $9,835.45.

Red Deer, Alta.—The steel on the C.P.R. line to the Brazeau coal fields, west from Red Deer, has reached a point west of Sylvan Lake, and will be completed to the Rocky Mountain House this winter. The C.P.R. has received running rights over the C.N.R. from the latter point to Brazeau.

Saskatoon, Sask.—The report from the civic electric light department for the month of November showed an increase of $4,570.60 in the income of the department and a reduction in the cost of producing power. In October the cost of producing power was 1.97 cents per kilowatt hour; in November, 1.93 per kilowatt hour.

Victoria, B.C.—The track-laying gangs of the C.N.P. from Edmonton have crossed the British Columbia boundary, steel having been laid some five miles westward up the Yellowhead Pass, 252 miles from Kamloops. North of Kamloops 96 miles of steel is laid, leaving only 156 miles as a final link.

Moose Jaw, Sask.—The rumor that the new C.P.R. passenger terminal was to be built at Moose Jaw this year has been denied officially. It is also understood that the new shops which were asked for will not be built this year; and from an official source the statement is made that very little work will be undertaken by the C.P.R. in Moose Jaw during the coming summer.

Forest, Ont.—On December 23rd, Mayor Pettypiece closed the switch that set in motion the new electric light service established this year in Forest. The plant has cost more than $20,000, and is the first public utility installed by the town. It is expected that it will prove to be a paying investment from its inception, and that a waterworks system will be the next undertaking of the municipality.

Prince George, B.C.—On the 10th of December the G.T.P. steel reached mile 200, which is 32 miles from Prince George; and it is expected it will be at the Fraser River opposite Prince George about the end of January. The driving of the last spike of the main line is announced by Mr. B. B. Kelleher, chief engineer for the G.T.P. company for next April, and the place as somewhere about 100 miles west of Fort George.

St. Catharines, Ont.—In connection with the $50,000 bonus to the Canadian Northern, it has developed that the company intends completing the line from St. Catharines to Hamilton within three years, and the section from Hamilton to Toronto within five years. An assurance to this effect has been given by Solicitor Temple on behalf of the company.

Victoria, B.C.—Work is progressing favorably along the line of construction on the Pacific Great Eastern. Mr. McQueen, purchasing agent for the company at Lillooet, speaks optimistically of the year's work, and indicates that expectations will be more than realized. Contrary to statements issued on the outside, he declares that the supply of labor is excellent, and the construction work is proceeding quickly.

Victoria, B.C.—A quantity of equipment for Victoria's electric light station has arrived, and mill permit of 100 additional arc lights being operated. Many of these lamps are now in position, but, owing to the redistribution of the circuits and the delay in the arrival of the new station apparatus, have not been put in operation. City Electrician Hutchison had had men at work all year rearranging some of the circuits, which have geen loaded to their full capacity, and on which no more new lights could be placed. These changes will provide for better facilities, especially in the northern sections of the city, and in the more remote outlying sections.

Ottawa, Ont.—The Government, through the National Transcontinental Railway Commission, has entered into a 99-year agreement with the C.P.R. and the G.T.P. for a union station at Quebec in connection with the National Transcontinental Railway. The new station is to be on the present site of the Palais Station, and will cost about one million dollars. Another union station, to accommodate St. Lawrence River traffic, will be built on the present site of the Champlain Market; and a tunnel will be built from Wolfe's Cove along the waterfront, giving railway entrance from the west for the National Transcontinental. The latter project will cost about $1,500,000.

Calgary, Alta.—The recent report of Superintendent McCauley shows that the proportion of operating expenses to revenue of the Calgary Street Railway for November, 1913, was 75.2 per cent. as compared with 68.4 per cent. for the corresponding month of last year. The total gross earnings were $60,670, a substantial increase over November, 1912, when the total was $56,233. Owing to the large increase in operating expenses, the net profit was $1,115.93 for November, 1913, contrasting with a net profit of $7,656.11 for November, 1912. A reduction in the cost of power of ¼ per cent. per kilowatt hour voted by council kept the net profits from appearing even still smaller than they were.

Victoria, B.C.—Recently, Mr. A. R. Tibbits of Ottawa, visited Victoria in the interests of the Marine and Fisheries Department of the Federal Government. His object was to collect first-hand information concerning the harbor conditions of Victoria and Vancouver; and, in response to an inquiry as to the merits of these ports, stated that:—"Victoria has a splendid natural harbor, easy to negotiate at all times, and capable of tremendous development; that the development is even now in progress; and that, when the work in progress is completed, the real significance of the port to the country will be better realized than it is to-day. The city of Vancouver is also wonderfully equipped in this respect.

Moose Jaw, Sask.—The result of the season's work at the headworks of the Moose Jaw system, all the water in the watershed at Sandy Creek can now be turned into the infiltration gallery, which has been completed to a total length

of 4,500 feet. The work upon the wells has not been as satisfactory. Contractor Duff has sunk a well 310 feet; but at this depth difficulty was met, and the casing bent, with the result that the whole work had to be undone. At present Mr. Duff is awaiting the arrival of a water jet with which he will endeavor to sink the well deeper. Another well, from which it was expected that a flow of 200,000 gallons per day would be secured, will be equipped with a pump very shortly, and the additional water will be added to the output of the system.

Edmonton, Alta.—Superintendent Parsons of the Edmonton waterworks department has estimated that in 1914 it will take $614,000 for the general operation of the plant, while $210,000 will be required for interest and sinking fund. The superintendent plans to make enough out of the plant to lay aside $100,000 for obsolesence fund. For the power plant, Superintendent Turner is asking for an expenditure of about $500,000 for new machinery and extensions; and estimates the revenue of the power plant as follows: for power sold to the electric light and power department, $504,726; for power sold to the street railway, $241,613; for pumping charges to the waterworks department, $176,982; making a total estimated revenue of approximately one million dollars.

Victoria, B.C.—Mr. H. A. Elgee, manager in Victoria, for the firm of Sir John Jackson, Limited, which is constructing the breakwater section of the Victoria harbor improvements, states that the progress to date is satisfactory in every way and that the work will be completed within contract time —December, 1915. About 300 men are engaged at present upon the work, either at Ogden Point, at the Albert Head branch, or on the office or general engineering staff. At the quarries, activity is now principally centred. Between 1,300 and 1,400 tons of rock are being taken out every day and deposited along the line of the breakwater, being transported to the harbor by five scows. And Mr. Elgee claims that it will not be long before the quarries will be so well developed that it will be possible to take out a much larger quantity of material than at present; that heretofore the work has been in every respect of a preliminary character; and that, anticipating this increase in the output of the quarries a new scow is being built for the work, while a steam hopper is being sent from Singapore. Another two months is expected to see the completion of the present operations which consist chiefly of depositing rock from Ogden Point out a distance of 1,000 feet, the object being to bring the breakwater up to a point 20 feet below low water mark. The character of this task can be appreciated when it is remembered that in some parts the water's depth is 70 feet. And, when this work is finished, the laying of granite blocks from Ogden Point out to sea, will commence.

Vancouver, B.C.—When unfolding to the waterworks committee recently the plan of the Federal Government for the development of False Creek, Mr. H. H. Stevens, M.P., said that the dredging facilities would be added to in order to complete the work of dredging the False Creek channel to a uniform depth and to a width of 350 feet; that it was the Government's intention to take over the old Kitsilano Indian Reserve of 80 acres and to develop it for public purposes, providing terminal facilities docks, piers, etc., for vessels and railways, in conjunction with the development of the creek; and that this would involve the expenditure of millions of dollars. While details of the whole scheme could not be outlined Mr. Stevens told the committee that the development work was very extensive, and that in view of this it would not be advisable to lay the Point Grey water main at a depth of 40 feet, which would, no doubt, interfere with the development scheme. However, when the plans had been worked out to completion it might be possible to devise a means of safely laying the pipes to a depth of 40 feet; and if the department thought that the laying of the pipe interfered with its plans, it would not grant permission for the pipes to be laid.

PERSONAL.

C. J. SIMMS, assistant division engineer of the Saskatchewan division of the Canadian Pacific Railway, with headquarters at Moose Jaw, has been appointed to a similar position in connection with the Vancouver division.

H. V. ARMSTRONG, who is at present on a brief holiday, returns to Estevan, Sask., next week as town engineer. Mr. Armstrong, a graduate in civil engineering of the University of Toronto, has spent 4½ years in Estevan, supervising the installation of a water supply, sewage disposal system, etc. The town will shortly go into the question of filtration of water supply.

H. B. WALKEM, who has been assistant division engineer for the Canadian Pacific Railway at Vancouver, B.C., for the past five years, and who, during 30 years of railway work in the West, has had charge of some prominent engineering works for the C.P.R., has been appointed engineer-in-charge of the Kootenay and Boundary districts, with headquarters at Nelson, B.C.

OBITUARY.

The death occurred recently of Mr. Alfred Williams, formerly associated with Mr. M. J. Heney in the construction of the White Pass Railway and of the Copper River and Northwestern Railway. Mr. Williams was president of the Ocean Shore Line, with headquarters in San Francisco.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

The annual meeting of the Canadian Society of Civil Engineers, will be held at Montreal on January 27th, 28th and 29th. A later issue will contain details of the arrangements.

COMING MEETINGS.

MINING AND METALLURGICAL SOCIETY OF AMERICA.—Annual Meeting will be held in New York City, January 13th, 1914. Secretary, W. R. Ingalls, 505 Pearl Street, New York.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

NATIONAL CONFERENCE ON CONCRETE ROAD BUILDING.—Meeting will be held in Chicago, Ill., February 12th to 14th. Secretary, J. P. Beck, 72 W. Adams Street, Chicago, Ill.

AMERICAN SOCIETY OF ENGINEERING CONTRACTORS.—Annual Convention to be held in New York City, January 16th. Secretary, J. R. Wemlinger, 13 Park Row, New York City.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Annual Meeting will be held in Montreal, Que., January 27-29. Secretary, Prof. C. H. McLeod, 176 Mansfield Street, Montreal, Que.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21029—December 16—Requiring C.P.R. to stop its trains Nos. 1 and 2 at Biscotasing to accommodate local passenger and express traffic at said station, and that such stops be scheduled in company's timetable.

21030.—December 15—Authorizing C.N.R. to open for traffic from Blaine Lake to Denholm, Prince Albert-Battleford Line, Sask., a distance of 42 miles: Provided speed of trains be limited to a rate not exceeding 15 miles an hour.

21031—December 15—Authorizing C.L.O. & W. Ry. (C.P.R.) to operate over crossing of K. & P. Ry. at mileage 24.8, Glen Tay to Cobourg Line, pending installation of interlocking plant required under Order No. 16490; trains of C.L.O. & W. Ry. and K. & P. to be brought to a stop and flagged over the diamond.

21032—December 16—Approving revised location C.P.R. Snowflake Westerly Branch Line, from a point on East Boundary, Sec. 14, thence in westerly direction to point on West Boundary of Sec. 14-1-11, W. P. M., mileage 8.08 to 9.10. 2. Approving location of said Snowflake Westerly Branch Line, from point on West Boundary of Sec. 14, to point on West Boundary of Sec. 15-1-11, W. P. M., mileage 9.10 to 10.12 on said Branch Line.

21033—December 16—Authorizing C.P.R. to construct extension to existing spur for Port Haney Brick Co., Limited, Haney, B.C., subject to terms of consent of Municipality of Maple Ridge.

21034—December 17—Authorizing C.N.R. to construct spur from main line, across Elm St., through Block 113, Parkdale, city of Edmonton, Alta., for Messrs. Pray and McLennan.

21035—December 16—Relieving C.N.R. from speed limitation of 20 miles an hour required under Order No. 15380, on Moose Jaw Extension from Radville to end of track, a distance of 83 miles.

21036—December 15—Granting leave to Corporation of city of Edmonton, Alta., to extend Spadina Ave. across G.T.P. Ry.'s tracks, Edmonton; Railway Co. to be at expense of constructing and maintaining the crossing.

21037—December 18—Extending, until June 1st, 1914, time within which G.T.R. install electric bell at crossing of public road by Co.'s tracks, west of Ste. Justine Station, Que., required by Order No. 20964, dated Dec. 4th, 1913.

21038—December 18—Approving location Kettle Valley Ry. Co.'s line from mileage 27.23 to 50, from Hydraulic Summit westerly to Penticton, B.C.

21039—December 20—Authorizing Confederation Construction Co. to operate crossing of G.T.R. by means of a flagman until March 1st, 1914, or pending installation and completion of interlocking plant required under Order No. 20996.

21040—December 16—Authorizing C.L.O. and W. Ry. (C.P.R.) to operate trains over crossing of Whitby, Port Perry and Lindsay Branch of G.T.R., at mileage 163.46, town of Whitby, Ont., until June 1st, 1914, subject to condition that crossing be protected by watchmen appointed and maintained by and at expense of C.L.O. and W. Ry.

General Order—No. 115—December 19—Suspending, for the present and pending investigation by the Board, the following tariffs:—G.T.R. Co.'s C.R.C. No. E. 2858; C.P.R. Co.'s C.R.C. No. E. 2716; C.N.R. Co.'s C.R.C. No. E. 358; M.C.R. Co.'s C.R.C. No. 2162; T.H. and B. Ry. Co.'s C.R.C. No. 945; and O. and N.Y. Co.'s C.R.C. No. 989.

21041—December 18—Amending Order No. 20811, dated November 13th, 1913, by striking out figures "193" in third last line of recital to said Order, and substituting therefore figures "192½."

21042—December 19—Approving and authorizing clearances as shown on C.P.R. plan showing clearances at siding for Canada Linseed Oil Mills, Limited, situated in Lot Cadastral No. 1586 (civic and Cadastral) St. Mary's Ward, Montreal: Provided men be kept off sides of cars while operating said siding.

21043—December 20—Extending, until August 1st, 1914, time within which subway at Brock Avenue, Toronto, be completed.

21044—December 19—Relieving G.T.R. from providing further protection at crossing of Brant Street, Burlington Junction, Ontario.

21045—December 20—Authorizing G.T.R. to operate over subway at highway leading to Cardinal, Ont.

21046—December 20—Amending Order No. 19296, dated May 8th, 1913, by striking out words "a grade" in 4th line of paragraph 3 of Order, and substituting therefore words "an overhead."

21047—December 18—Directing G.T.R. to construct at Prairie Siding a small freight shed and platform to accommodate traffic offering, put present shelter for passenger traffic, in proper repair, make necessary arrangements to keep same in a clean and proper condition.

21048—December 17—Directing Dominion Atlantic Ry., at its own expense, to provide suitable farm crossing where it crosses property of R. V. Ditmars, of Deep Brook, N.S.

21049—December 20—Authorizing C.P.R. to construct siding for Stag Creek Lumber Co., Eastman, Que. 2. C.P.R. is authorized to construct, maintain and operate extension to present siding for said Stag Creek Lumber Co., to be completed within six months from date of this Order.

21050—December 10—Authorizing G.T.R. to construct sidings to serve premises of Imperial Wire and Cable Co., Limited, on part Lot 992, St. Anne's Ward, city of Montreal, Que.

21051—December 22—Authorizing C.N.O.R to construct bridge across South Branch of Petawawa River, Tp. Stratton, Dist. Nipissing, Ont., at mileage 121.9 west of Ottawa.

21052—December 19—Rescinding Order No. 20908, dated November 27th, 1913. 2.—Authorizing C.N.R. to remove branch line of railway on spur along Ninth Street, Brandon, between Victoria Avenue and Brandon Avenue, said city.

21053—December 22—Extending, until December 31st, 1914, time within which C.N.O.R. complete transfer track between its railway and G.T.R. in town of Port Hope, Ont.

21054—December 22—Approving plan "A" showing spans at C.N.O.R. bridge over Mink Creek, Tp. Pentland, Ont., at mileage 185.52 from Ottawa.

21055—December 22—Extending, until February 22nd, 1914, time within which C.P.R. complete spur, or switching lead, in city of Toronto, authorized by Order No. 20385, September 22, 1913.

21056—December 18—Approving location C.P.R. station at mileage 71.36 from Glen Tay, Lot 26, Con. 1, Tp. Thurlow, Co. Hastings, Ont.: Provided whenever traffic is blocked for more than 5 minutes at any one time by reason of location hereby approved, Board shall be at liberty to re-locate station.

21057—December 18—Approving proposed location C.P.R. station at St. Joachim, Lot 5, River Ruscom, Range West, Tp. Rochester, Co. Essex, Ont. And rescinding Order No. 19291, dated May 14th, 1913, granted herein.

21058—December 19—Authorizing C.P.R. to construct extension to existing spur lying southwesterly of Sherbrooke Street, and southeasterly of Harriott Street, Perth, Ont., for Henry K. Wampole and Co., at mileage 11.6, Ont. Div. Havelock Subdivision.

21059—December [illegible]—Authorizing C.P.R. to reconstruct Bridge No. 55.0 over Naiscootyong River, near Naiscoot, Ont.

21060—December 22—Authorizing C.P.R. to construct, by grade crossing, its passing track, on main line, Broadview Subdivision, across road allowance between Secs. 25 and 26-9-25, W.P.M., at mileage 25.45 on main line.

21061—December 22—Authorizing C.P.R. to construct, by grade crossing, its passing track, on main line, Broadview Subdivision, across road allowance between Secs. 22 and 23-9-24, W.P.M., at mileage 32.43 on said main line.

21062—December 22—Authorizing C.P.R. to reconstruct Bridge No. 1.9 on Prescott Subdivision, Eastern Division, Dist. No. 4 of its railway.

21063—December 22—Authorizing G.T.P. Ry., at his own expense, to construct across and divert highway in N.E. ¼ Sec. 1-27-15, W. 2 M., mileage 24, rural municipality No. 247, Dist. Saskatoon.

21064—December 22—Extending, until May 31st, 1914, time within which G.T.R. complete siding for Farquharson-Gifford Co., Limited city of Stratford, Ont., authorized under Order No. 19874.

21065—December 18—Relieving G.T.R. from providing further protection at crossing of public road 1 mile south of Brunner, Ont.

21066—December 22—Authorizing Kettle Valley Ry. Co. to construct four (4) bridges in British Columbia—namely, 1. Over Trout River Creek, at mileage 7 west of Penticton. 2. Over Trout Creek, mileage 36.8 west of Penticton. 3. Over Trout Creek, mileage 24.4 west of Penticton and 4. Over Trout Creek, at mileage 23.15 west of Penticton.

21067—December 22—Authorizing Government of Saskatchewan, to construct, at its own expense, highway crossing over C.N.R. at west end of station grounds at Pinkham, Sec. 28-28-25 W. 3 M., Sask.

21068—December 22—Approving location C.P.R. station in town of Milton, Co. Halton, Ont., at mileage 32.1, London Subdivision.

21069—December 22—Authorizing C.P.R. to take certain lands in town of Milton, Ont., for purpose of enlarging its yard.

21070—December 22—Authorizing C.P.R. to construct, extension to existing siding for Oliver Lemire, Cabane Ronde, Mascouche, Que., in Lot Cadastral, No. 155, Con. de Cabane Ronde, at mileage 15.88 from St. Martin Junction.

21071—December 20—Authorizing C.P.R. to construct spur with siding therefrom for Balsam Lake Quarries, Limited, Toronto, Ont., from a point on southerly limit of right of way at mileage 35.07 from Port McNicoll, Ont.

21072—December 22—Relieving G.T.R. from providing further protection at crossing of public road 1 mile south of Elmvale, Ont.

21073—December 22—Authorizing C.P.R. to construct spur for Kelley and Anderson, Bonfield, Ont., in Lot 10, Con. 8 Tp. of Bonfield, Dist. Nipissing, Ont., at Bonfield.

21074—December 22—Relieving G.T.R. from providing further protection at crossing of first public highway east of Glencoe, Ont.

General Order—No. 116—December 24—Suspending, for the present and pending investigation by the Board, increased minimum carload weights on buckwheat, oats bran (in bulk), dried beet pulp, oat hulls (in bulk), pea hulls (in bulk), chorts, beets (except sugar), onions, turnips and potatoes, as filled by Railway Companies subject to jurisdiction of the Board.

21075—December 22—Authorizing C.P.R. to construct spur for Imperial Supply Co., Limited, in Subdivision Lots 4, 5 and 6, Block 64, city of Calgary, Alta.

21076—December 22—Authorizing, C.P.R. to construct Bridge No. 94.4 for double-tracking, Toronto Subdivision, Don Viaduct; cost of alteration in work required by opening between pedestals be borne and paid by city of Toronto.

21077—December 23—Authorizing C.P.R. to construct sidings for Ontario National Brick Co., Limited, from a point on southeasterly limit of right of way at mileage 16.02, near Cooksville, in Lot 19, Con. 1, north of Dundas Street, Tp. Toronto, Ont.

21078—December 22—Authorizing C.P.R. to construct spur into premises of A. Morely, Lot 12, Con. 9, Tp. Huntingdon, Ont.

21079—December 22—Authorizing C.P.R. to open for traffic its Euffield-Blackie Branch from mileage 26.3 to 57.2, Alta.; speed of trains to be limited to rate not exceeding 15 miles per hour.

21080—December 22—Directing C.N.R. to fence its right of way in S.E. ¼ Sec. 21-7-25, W. 4 M., Alta.; work to be completed by May 1st, 1914.

21081—December 19—Extending, until June 30th, 1914, time within which Dominion Atlantic Ry. equip its locomotives with ash pans that can be dumped or emptied without the necessity of any employee going under such locomotive, except in cases of emergency.

21082—December 15—Extending, until July 1st, 1914, time within which C.P.R. equip its locomotives with ash pans that can be dumped or emptied without any employee going under such locomotive, except in cases of emergency.

21083—December 22—Authorizing Algoma Eastern Ry. to operate bridge at Little Current, between Goat and Manitoulin Islands, Ont.: Provided all trains come to a full stop at signboards and do not proceed over drawspan before signal is given by bridge operator.

21084—December 22—Authorizing Edmonton Interurban Ry. to operate cars and trains over crossing of Edmonton, Dunvegan and B.C., in N.W. ¼, Sec. 25-53-25, W. 4 M., Alta., without being brought to a stop; trains of Edmonton, Dunvegan and B.C. to be operated over said crossing at speed not exceeding 15 miles per hour.

21085—December 23—Authorizing Ontario Pipe Line Co., Limited, to lay gas pipe along, upon and across bridge over G.T.R. on Bay Street, Hamilton, Ont., subject to and upon certain conditions.

21086—December 24—Authorizing Canada Southern Ry. to cross with its industrial siding the industrial siding of G.T.R. leading to Canadian Steel Foundries, Limited, Tp. Crowland, Co. Welland, Ont., subject to terms and conditions contained in an agreement between Applicant and G.T.R.

21087—December 24—Ordering and adjudging that Board has jurisdiction to entertain application—of city of Hamilton for an Order compelling T.H. and B. Ry. to divert its entrance into city of Hamilton, via Hunter Street and adopt in conjunction with G.T.R. and C.N.O.R., a common location in north end of city, etc.—and to make an Order directing the deviation of line of T.H. and B. Ry., within the distance of one mile from its present location.

21088—December 23—Extending collection and delivery limits of Dominion Express Co., in city of Lethbridge, Alta.; and rescinding Order No. 16043, dated February 26th, 1912.

21089—December 23—Establishing collection and delivery limits of Dominion Express Co., in city of Vernon, B.C.

21090—December 26—Extending, until February 28th, 1914, time within which C.P.R. install bell at crossing of Main Street, village of Shelburne, Ontario.

21091—December 23—Authorizing C.P.R. to construct siding into premises of H. De Chiree, Lot Cadastral, No. 136, Con. St. Martin, parish of St. Felix de Valois, Co. Joliette, Quebec.

21092—December 24—Authorizing C.P.R. to operate bridge on Runnymede Road (Elizabeth Street), West Toronto, Ontario.

21093—December 24—Authorizing C.P.R. to operate bridge on Jane Street, Tp. York, Ontario.

21094—December 24—Extending, until January 15th, 1914, time within which G.T.R. install interlocking plant at Paris Junction, Ont.

21095—December 23—Approving location G.T.P. Ry. station at Tatlow, mileage 232.4, Prince Rupert East, Sec. 32-5-5, Coast District, B.C.

21096—December 26—Extending, until May 1, 1914, time within which C.P.R. complete subway at Dundas Street, Woodstock, Ont.

21097—December 26—Extending, until February 28th, 1914, time within which C.P.R. install bell at crossing of Main Street, Milverton, Ont.

HOW THE STRENGTH OF WOOD IS TESTED IN CONSTRUCTION

A STUDY OF THE PROPERTIES OF THE VARIOUS KINDS IN USE—EFFECT OF MOISTURE CONTENT UPON STRENGTH—CONDITIONS AND NATURE OF TESTS — STRENGTH OF CANADIAN SPECIES

By A. H. D. ROSS,
Faculty of Forestry, University of Toronto

FROM time immemorial, wood has been used for construction purposes more than any other material, yet it is a curious fact that our information regarding its strength is not nearly so complete as in the case of steel, cement and other materials which have come into use in comparatively recent times. For a few kinds of wood our knowledge of their strength is fairly satisfactory, for a number of others it is still rather vague, whilst for the great majority of them it is almost a negligible quantity.

Selection of Material.—Every wood-worker knows that great variations occur in the appearance, weight, hardness and strength of any given kind of wood. For example, heartwood differs from sapwood, body-wood from limb-wood, butt logs from top logs, etc., etc., and it is therefore a matter of great importance to know the origin of the material being tested and the conditions under which it was grown. A piece of wood is not simply a material but a *structure*, just as much as a railroad bridge or a balloon frame, and as such varies greatly even in wood from different parts of the same tree. The fact of the matter is that it is almost impossible to understand the behavior of the material being tested without a somewhat intimate knowledge of its internal structure, because the size, character and arrangement of the tiny fibres composing it have a very important bearing upon its behavior when subjected to external forces. This is well illustrated in the case of weight, strength and hardness, which are closely related to the thickness of the cell walls. Unlike metals and artificial products with a homogeneous structure, such as steel and cement, wood is an exceedingly complex and heterogeneous structure, and it is therefore necessary to consider separately the stresses applied to it and the resultant strains.

Methods of Testing.—The strength of a piece of wood may be tested for: Elasticity; cross-breaking strength; endwise crushing strength; crushing strength across the grain; shearing strength; hardness; tension along the grain; or, torsional strength.

So far, most of the studies conducted have been for the determination of elasticity, cross-breaking strength, and endwise compression strength, whilst crushing strength across the grain, shearing strength, hardness, etc., have received comparatively little attention.

Whilst the various tests are made separately, it is, of course, evident that the fitness of wood for a given purpose depends upon a combination of several qualities. For example, railroad ties must be hard enough to resist mechanical abrasion, strong enough not to break and tough enough to prevent splitting and to hold spikes; a wagon spoke must be stiff, strong, hard, resilient and tough; furniture wood should be hard enough to resist indention, take a good polish, etc., etc.

Importance of Knowing Moisture Content.—One reason for dry wood being so much stronger than green material is due to the increased number of woody fibres to the square inch as the material seasons, and it is worthy of note that this increase in strength does not become apparent until the percentage of moisture falls below 40% of its kiln dry weight. The explanation of this lies in the fact that for more than 40% of moisture the water fills not only the cell walls but also the cell cavities themselves. As the weakening effect comes only from the wetting of the cell walls, it therefore follows that after they are fully saturated, any excess of water which occupies the cell cavity would be inoperative. Consequently, no increase in strength is noticeable until the cell walls themselves begin to dry out—after which the increase in strength takes place very rapidly, and becomes approximately two and one-half times that of the wood as it comes from the tree, as shown by the following figures (Table I.) by Tiemann:—

It should be clearly understood that the percentage of moisture is always calculated upon the weight of the wood when absolutely dry.

TABLE I.

	Bending Strength.		Endwise Crushing Strength,	
	12% Moisture.	3½% Moisture.	12% Moisture.	3½% Moisture.
Long leaf pine . . .	1.5	2.5	1.7	2.9
Red spruce	1.9	2.8	2.4	3.7
Chestnut . . .	1.6	2.1	1.8	2.8

Much of the pioneer work in testing the strength of wood is unreliable because sufficient care was not exercised in determining either the percentage of moisture present in the test pieces or their physical structure, both of which have a most important bearing upon the strength of wood. In fact it is only recently that these sources of weakness or strength have been studied exhaustively, and even yet an enormous amount of work remains to be done before our knowledge of the subject has been placed upon a satisfactory basis.

Previous to 1896 Johnson's figures for the strength of timber were based upon the assumption that it contained 15% moisture, but since then they are given for wood containing 12% moisture; as representing the condition of well-seasoned wood. In a dry-heated building the moisture content often falls as low as 8% or 10%.

Testing Laboratories.—In Europe many tests have been made by Bauschinger, Laslett, Tetmayer, Julius, Barlow, Tredgold, Warren, H. D. Smith and C. Graham Smith; whilst in the United States of North America the strength of several commercial species has been investigated by Johnson, Sharpels, Lanza, Tiemann, Thurston, Trautwine, Unwin and others. Unfortunately, however, the methods of testing and the varying percentages of moisture present in the specimens used have varied so much that it is impossible to reduce the results obtained by a number of these investigators to a satisfactory basis for comparison.

This whole subject of the strength of wood is of such importance to engineers and builders that in recent years the United States Forest Service has established wood-testing laboratories at Washington, D.C.; New Haven, Conn.; Madison, Wis.; Seattle, Wash., and a number of other places where the leading commercial species of the region are being investigated according to a uniform plan. From time to time, the results obtained are published in bulletins and circulars which may be obtained from the Superintendent of Documents, Washington, D.C., for a merely nominal charge.

Elasticity.—Elasticity refers to the ability of a horizontal beam of given dimensions to recover from a given amount of deflection, or "sag," when the force which has produced the deflection is removed, and is therefore closely related to stiffness. Obviously, pressure applied transversely to a beam of wood has a tendency to break the fibres across, and in modern testing machines is applied gradually to a system of levers by means of small weights or hydraulic pressure, and the force exerted upon the specimen is indicated by a delicately adjusted steel-yard. To avoid shearing along the grain the length of the beam should be ten to twenty times its depth, and to minimize the amount of crushing across the grain-bearing plates of the same width as the beam are used. The distance to which the middle point of the beam is forced down is termed its "deflection," and may be indicated by means of the letter d; the readings being taken to hundredths of an inch for large beams and to thousandths of an inch for smaller ones. For solid rectangular beams repeated tests have shown that the "modulus" or measure of elasticity varies directly as the pressure applied at their centre and the cube of the distance between the points of support, and inversely as their breadth and the cube of their depth. This explains the common practice of setting flooring joists on edge, which enormously stiffens the whole structure. For example, if the joists consist of 2 x 10-inch material, then setting them on edge and placing diagonal braces between them to keep them in position gives a floor $\frac{2}{10}$ of $\left(\frac{10}{2}\right)^3 = 25$ times as stiff as if they were laid flatwise. In practical engineering the load acts continuously and it has been found that the deflection for wooden beams should not exceed $\frac{1}{480}$ of their length; which would amount to only half an inch for a 20-foot beam.

Stress Diagrams.—When the deflections, in inches, are plotted on the horizontal axis of a sheet of cross-section paper and the number of pounds pressure required to produce these deflections are plotted on the vertical axis, it is found that the series of points obtained gives us a curve which is practically a straight line up to a point known as the "elastic limit"; beyond which it still continues to rise but soon curves away from the straight line to another point known as the "maximum load." After this it descends gradually because of the failure of the piece being tested, as is well shown in the accompanying diagram (Fig. 1) for a piece of fairly straight-grained red spruce having a span of 14 feet between the roller bearings and measuring 6 inches in width and 8 inches in height. From the diagram it will be noticed that the

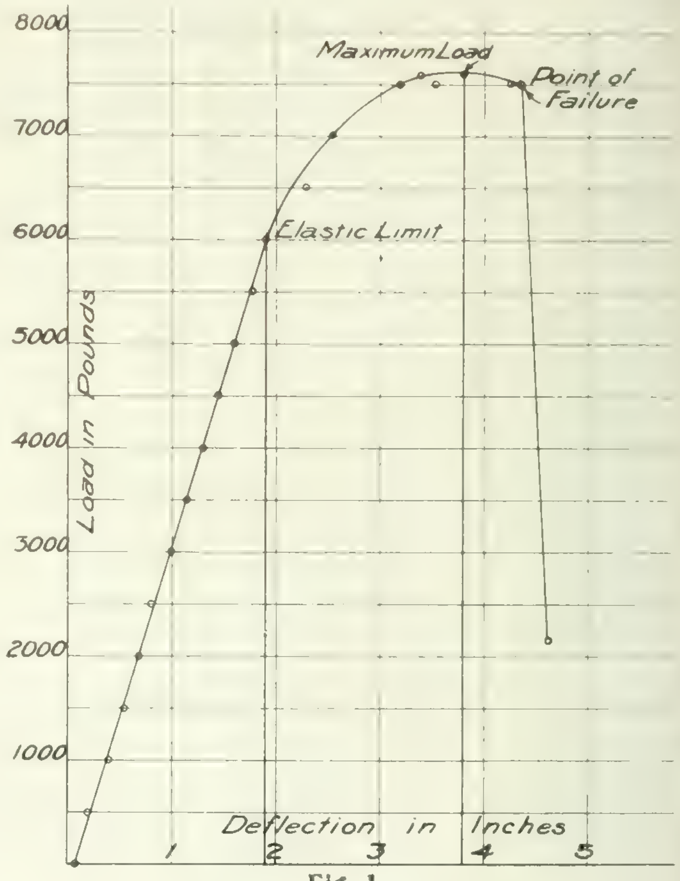

Fig. 1.

elastic limit was reached under a strain of 6,000 pounds and the maximum load at 7,580 pounds. Disks cut from the beam near the point of failure and dried in a steam-heated copper kiln showed moisture content of 25%, 33% and 42; according to the distance they were taken from the surface.

Modulus of Elasticity.—From the reading obtained at the elastic limit, the deflection observed at that pressure and the dimensions of the piece tested we may calculate what is known as the "modulus of elasticity" by means of the formula

$$E = \frac{w\, l^3}{4\, d\, b\, h^3}$$

where w represents the pressure in pounds midway between supports, d the deflection or "sag" in inches, l the number of inches between the horizontal supports, and b and h the breadth and height of the beam, in inches. Any

five of these quantities being known it is an easy matter to calculate the sixth. For example, in the case of our red spruce beam, 6,000 pounds pressure produced a deflection of 1.9 inches, whence we have

$$E = \frac{6,000 \times 168 \times 168 \times 168}{4 \times 1.9 \times 6 \times 8 \times 8 \times 8}, = 1,244,842.$$

Conversely, if we know the value of E and wish to calculate what weight will produce a sag of 2 inches in a red spruce beam similar to the one tested, but six inches square and having a span of ten feet, then we have the equation

$$1,244,842 = \frac{w \times 120 \times 120 \times 120}{4 \times 2 \times 6 \times 6 \times 6 \times 6}, \text{ whence } w = 7,469 \text{ lbs.}$$

Cross-breaking Strength.—When forced beyond the elastic limit the piece being tested acquires a permanent set and finally breaks at what is known as the "point of failure," or "maximum load." When this occurs the "modulus of rupture" is calculated by means of the formula $R = \frac{3\ W\ l}{2\ b\ h^2}$, which in the case of our red spruce beam gives us $R = \frac{3 \times 7,580,168}{2 \times 6 \times 8 \times 8} = 4,974.$

For bending tests of this kind the early experimenters used small pieces because of the difficulty in holding and bringing strains to bear upon larger ones. Bauschinger used beams 20 inches square and nine feet long with 98.4 inches between their supports. At the Massachusetts Institute of Technology, Lanza used beams varying from four to twenty feet long, from 2 to 6 inches in width and from 2 to 12 inches in depth. In Johnson's work on large beams, smaller pieces (measuring 4 inches square) were cut from the large ones as soon as they failed and were then tested to see whether the same *moduli* would apply, and this was found to be the case *whenever similar conditions existed.*

Many Tests Required.—On account of the great variations that occur in the weight of any kind of wood, the proportion of heartwood to sapwood, differences in minute structure due to different conditions of growth or of wood taken from different parts of the same tree, and the enormous variations that may occur in the moisture content of the test pieces, it is evident that reliable figures on the strength of wood must be based upon the average of a large number of tests. The following figures (Table II), for the cross-breaking strength of woods containing 12 per cent. moisture, show a wide range.

TABLE II.

Species.	No. of tests.	Highest single test.	Lowest single test.	Average of all tests.
Pignut hickory ...	30	25,000	11,000	18,700
Shagbark hickory .	187	23,300	5,700	16,000
White oak	218	20,300	5,700	13,100
Red oak	57	16,500	5,700	11,400
Red pine	95	12,900	3,100	9,100
White pine	120	11,800	4,600	7,900
White cedar	87	9,100	3,500	6,300

Effect of Permanent Loads.—Thurston experimented on small wooden beams one inch square and four feet long for the purpose of determining the effect of permanent loads on their strength as compared with the results obtained with testing machines, and found that 60 per cent. of the breaking load in the machine would break the beams if the load was left on them for nine months time. Later on Johnson experimented with well-seasoned wooden columns and came to the conclusion that "The ultimate strength of wooden columns is only about one-half the utilimate strength of those same columns as determined by a testing machine."

Endwise Compression.—The failure of a piece of wood under pressure along the grain is a very complex phenomenon. At first the fibres act like a number of hollow columns firmly bound together, but as the load becomes too great they tear apart and act as a number of independent pieces and finally bend over when the piece fails. In all test pieces it is advisable to have the length less than 15 times the least diameter, else they are liable to fail by bending sideways before the full load they are capable of sustaining is reached. A number of tests of West Australian timber showed that 60 per cent. of the columns having a ratio of 18 to 1 failed in this way, and every builder is familiar with the common practice of bracing the studding in a wall to prevent the failure of the upright pieces by sidewise flexure. The endwise compression strength of wood is given in pounds per square inch, and is read directly from the testing machine. Johnson says that the result of over 40,000 tests shows that 55 per cent. of the results fall within 10 per cent. of the general average and that 90 per cent. of them fall within 25 per cent. of the general average. This is a greater range of variation in strength than is usually found in other kinds of building material, and is partly due to variations in the structure of the wood itself. The following figures (Table III), illustrates some of the variations that occur.

TABLE III.

Endwise Compression, in Pounds Per Square Inch.

(For 12% moisture).

Kind of wood.	No. of tests.	Highest single test.	Lowest single test.	Average of all tests.
Pignut hickory ..	30	13,000	8,700	10,900
Shagbark hickory .	137	13,700	5,800	9,500
White oak	218	12,500	5,100	8,500
Red oak	57	9,700	5,400	7,200
Red pine	100	8,200	4,300	6,700
White pine	130	8,500	3,200	5,400

In spite of the complex nature of woody structures it is rather a surprise to learn that properly designed wooden columns will support a greater load than an equal weight of cast-iron or steel of similar proportions.

Crushing Strength Across the Grain.—A timber column is frequently designed for its maximum load and is then set on a sill of the same wood without knowing that the crushing strength across the grain is very much less than it is in the endwise direction. Many failures of timber structures are due to this cause alone. For very heavy loads, it is therefore, advisable to use caps and sill pieces to distribute the load and thus prevent crushing across the grain as much as possible. The crushing takes place layer by layer and woods with thin-walled fibres, like pine and spruce, give way sooner than those with thicker walls, such as oak and hickory. Furthermore, in woods containing large pith rays, like oak and sycamore, the crushing strength in the radial or "edge-grain" direction is greater than in the tangential or "slash-grain" direction. Naturally the greater the percentage of moisture present the more easily the wood crushes, as is well illustrated in Table IV.

TABLE IV.

Kind of wood.	Percentage moisture.	Pounds per square inch.	Percentage moisture.	Pounds per square inch.
Shagbark hickory ...	58	1,080	9.8	2,717
Sugar maple	56	870	12.5	1,755

Red pine	54	358	12.5	833
Western yellow pine ..	125	320	9.7	805
Lodgepole pine ...	46	364	11.0	779
Douglas fir	32	427	12.0	744
White pine	75	314	9.9	757
Western hemlock	129	420	9.5	726
Red spruce	31	322	12.9	531
White spruce	41	262	12.0	455
White cedar	55	288	11.2	389

Shearing With the Grain.—Shearing strength refers to the force required to push a piece of wood in the direction in which its fibres run, and has its practical application in the strains exerted on mortise and tenon structures. The lighter conifers and hard woods shear more easily than the heavier kinds, and the best of pine from one-third to one-half as easily as hickory or oak. Surfaces parallel to the annual rings shear more easily than those parallel to the pith rays and green wood about one-third as easily as dry wood. Table V. shows the shearing strength of ten well known woods which have been kiln dried and contain specified percetages of moisture.

TABLE V.

Kind of wood.	Percentage of moisture.	Shearing force (pounds per square inch).
Shagbark hickory	9.6	2,290
Bitternut hickory	9.7	2,048
White oak	12.1	2,165
Black oak	11.6	2,005
Red oak	11.2	1,845
White ash	10.8	1,522
White elm	10.8	1,447
Red pine	12.5	1,262
White pine	9.9	1,072
White cedar	11.2	902

Hardness.—From the carpenter's point of view, hardness refers to the resistance of the fibre of wood to axe, saw, chisel or plane, and will depend upon such factors as density, moisture content, etc. Wide rings in oak and narrow rings in pine increase the hardness; heartwood is harder than sapwood; and, dry wood is harder than green wood—excepting willow and poplar. The static test for hardness used to be to note the number of pounds pressure per square inch required to force a square die into the wood to a depth of one-twentieth of an inch, but as this included shearing across the grain for two edges of the die and shearing along the grain for the other two edges the method now adopted is to record the number of pounds pressure required to force a steel ball .444 inches in diameter into the wood a distance equal to half its own diameter. Such tests show that wood is harder in an endwise direction than it is across the grain. Partly for this reason, but mainly because the endwise crushing strength of wood is much greater than its crushing strength across the grain, it is customary to set paving blocks on end.

Table VI., for the hardness of 16 well-known woods, exhibits, in a rather striking manner, how very much harder any kind of well-seasoned wood is than the same material as it came from the tree.

TABLE VI.

Kind of wood.	Percentage moisture.	Pounds pressure required to imbed a .444 inch ball to ½ its own diameter. Endwise.	Sidewise.
White oak	62	1,087	1,048
	12.8	1,520	1,487
Sugar maple	57	992	910
	10.3	1,942	1,346

Western yellow pine	98	310	314
	11.6	546	408
White cedar	55	321	226
	11.2	466	338

Tension Along the Grain.—The tensile strength of straight-grained wood is very high and hard to measure because of the difficulty of preventing the ends of the test pieces from slipping in the shackles of the testing machine. However, it is not often that a wooden beam is used for a tie bar. For rock elm the tensile strength along the grain is approximately 28,000 pounds, or 3.8 times its endwise crushing strength; for shagbark hickory 32,000 pounds, a ratio of 3.4; for tamarack 19,400, or 2.5; and for long-leaf pine 17,300, or a ratio of 2.2 to 1. Hence, in a general way, we may say the tensile strength of the tougher woods is approximately three times their endwise compression strength.

The tests of most interest to the architect and the engineer are those for cross-bending, crushing and shearing. Long before the timber would give way in tensile strength the bolts or connections would shear through the ends of the timber, and for this reason it is customary to place them at least three or four inches from the ends of the beam required to bear tensile stress.

Torsional Strength.—The torsional strength of wood refers to the ability of its fibres to withstand twisting and is measured by securely fastening one end of the rod at one end of a lathe and clamping the other end in a wheel which can be rotated until the fibres of the wood are completely twisted and torn asunder. Hickory, rock elm, blue beech and willow possess this property in a marked degree.

Flexibility.—This property depends upon the toughness and cohesive force of the woody fibres, the percentage of moisture present, the temperature and the amount of natural or artificial impregnation. Wood from the base of the tree is more flexible than that obtained higher up, and hardwoods are generally more flexible than conifers. For all kinds of wood, moisture and heat soften

it and increase its flexibility, as is well illustrated in the manufacture of bent-wood furniture, barrel staves and hoops, the bending of wooden rims for wheels, veneer peeling, etc.

Toughness.—This is a more or less general term applied to woods which are both pliable and rather difficult to split. When the dry wood permits of an aggregate distortion in compression and tension of at least 3% and resists a longitudinal shearing force of 1,000 pounds per square inch it may be pronounced "tough," as for example, hickory, ironwood, oak, elm, ash.

Resilience.—This term is often confused with toughness and may be defined as ability to withstand impact, and explains the use of oak and hickory for wagon spokes, where each spoke is dealt hundreds of terrific blows in a mile journey over a rough road. Maple, beech, hawthorn and dogwood also have a high resilience.

Weight and Strength.—Broadly speaking, the strength of well-seasoned wood increases with its weight per cubic foot, the exceptions being confined mainly to the oaks which have an exceedingly complicated structure. To state the case more accurately, we may say, the higher the density of the wood the greater is its crushing strength, although density is no criterion of tensile strength.

Effect of Long Immersion in Water.—Sixty-five tests on alternate sections of the same sticks tested in the regular way indicate that soaking in water for six months produces no apparent loss of strength. Whilst soaking in cold water does not diminish the strength of wood, it is a well-known fact that heating the water weakens it considerably and boiling the water causes a still greater dimunition in strength, as noted already under the heading of flexibility. Timber which is first kiln dried and then soaked in water is found to be weaker than air dry timber containing an equal percentage of moisture, and fails much more suddenly because kiln drying increases the permanent brittleness of wood.

Effect of Hot Air Drying.—Apart from the checking action which results from a too rapid drying of the exterior portions of the test pieces, the result of over 200 tests shows that with the temperatures commonly used for drying lumber no detrimental effect was observed on the strength of the material.

Effect of Creosoting.—The following figures (Table VII.) for compression tests made on pieces of loblolly pine which had been soaked in water and in creosote for six days are interesting:

TABLE VII.

	Length of soaking (days).	Moisture %.	Relative load.
Air dry wood	0	9.1	1.00
Soaked in water	6	71.5	.42
Soaked in creosote	6	[illegible]	.80

These figures show that creosote diminished the strength of the wood approximately one-half as much as soaking in water. It should be remembered, however, that these tests were made on very small pieces, and the results should be received with caution. More recent experiments show that whilst the strength decreases immediately after being creosoted this decrease is only temporary. Apparently the presence of creosote does not of itself weaken the wood but only retards the seasoning process, so that after a time it should become as strong as the original seasoned wood.

Safety Factors.—On account of such defects as knots, season checks, star-shake, etc., present in most structural timber and the great variation constantly occurring in its moisture content, it is customary to design timber structures so that they will carry several times the load ordinarily required—this multiplier being known as a safety factor. In the case of ordinary timber structures a safety factor of four is generally sufficient, provided the modulus of rupture has been determined from a large number of tests on fairly large-sized pieces, but in the case of structures carrying moving or jarring loads (bridges and foundations for machinery) a safety factor of five or six should be allowed.

In 1896 a committee of the American International Association of Railway Superintendents of Bridges and Buildings recommended the following factors: For timber in shearing and compression across the grain, 4; for columns under 15 diameters high and for end bearing, 5; for extreme fibre stress in transverse rupture, 6; in tension with and across the grain, 10.

Testing of Canadian Woods.—Because of the importance of this subject to all classes of wood users, the Forestry Branch of the Department of the Interior is about to undertake an exhaustive series of tests at McGill University. Beginning with a few of the more important of the commercial species, every kind of wood in the country will be tested for its strength in various ways, and for different conditions of growth and moisture content. At present the only information we have on this subject is based upon tests of wood grown in the United States; many of which were grown under entirely different conditions to what we find in our own country.

Provisional Table.—In the absence of more satisfactory information, the writer has therefore compiled the following table (Table VIII.) for 84 species of wood found growing in Canada. The necessary information has been gleaned from numerous sources and will be of considerable assistance to the designers of timber structures until such time as the Forestry Branch has completed its investigations along this line and furnishes fuller information regarding the strength of our native woods.

(Continued on following page.)

CANADIAN FOREST FIRES IN 1913.

The Forestry Branch, Department of the Interior, announces that the loss of timber by fire in Western Canada was smaller during last season than ever before. On several of the reserves in Manitoba and Saskatchewan fire occasioned no damage whatever, and on the Dominion reserves in the Railway Belt, B.C., the only green timber injured by fire was four acres of young lodgepole pine. Even on the Rocky Mountains reserve in Alberta, with the immense area of 13,373,856 acres, most of which is remote from settlement, fire destroyed only 1,150 acres of young timber, whose present value was small, and mature timber to the value of $150. The total area burnt on this reserve was but two one-hundredths of one per cent. of the above acreage, and it is likely, when the reports are complete from the other reserves, which are smaller and usually better protected, that the aggregate area burnt over by fire will be no greater than one one-hundredth of one per cent. of the total reserved area. The significance of this figure is apparent by comparison with the corresponding figure for the National Forests in the United States, where the area burnt over by fire in 1913, although admittedly the smallest in recent years, was about 0.03 per cent. of the total area.

FACTORS GOVERNING THE SELECTION OF A ROAD SURFACE OR PAVEMENT.*

By L. R. Grabill,
Superintendent of Suburban Roads, Washington, D.C.

THE selection of a pavement or road surface is one of the most important of the duties of a highway engineer. The surface of the road or street, equally with the bridge truss or the retaining wall, should be neither over-designed nor under-designed as to the strength required to satisfy the conditions which it will be called upon to meet. In this particular the discrimination and care used must be similar to that of the architect in choosing the type of building suited to the case he has in hand, and to that of the bridge engineer in selecting the kind of bridge he will use. The roadbuilder or the pavement engineer must choose not only the type of surface which will be the easiest over which to pull a load, which will prove durable under the traffic that it will carry, and which will be adapted to the numerous local conditions; but he must, if his work is properly done, choose the surface that will produce these results with the minimum final cost both to the users of the road and to the community which pays for its construction and maintenance.

Nothing could be easier than to select a few types of road suitable to a few locations, and to adhere to these types, regardless of wide variations in the conditions; and this, it is feared, is too often done. It is very much on the safe side to assume that the character of pavement required for the most exacting purpose should be used for very different and lighter requirements; or to assume that the surface which costs the most will necessarily be the best; but it is not always possible to decide with such facility the question of what surface will prove the most satisfactory, under the special conditions involved, for the lowest total expenditure per ton carried over it. Yet this is the question to be solved in every new construction.

There is frequently the danger, too, that a lack of sufficient funds for the work proposed will cause the effort to be made to cheapen the first cost of construction beyond the limit necessary for durability; and it is not often that the road engineer finds enough funds available to build a better road than he wishes, if indeed he is able to build as well as his judgment dictates. In these cases, however, it is usually possible to limit the area covered, either in length or width, or both, so that a suitable character of surfacing may be employed.

It is assumed here that all of the necessary requirements for the sub-grade have been met, such as those that relate to grade, drainage, and the preparation of the earth foundation for the pavement. These being the necessary and most permanent part of the road, should always be well done, in the best and most enduring manner that is practicable with the funds available, even at a sacrifice of the character of the surfacing, which will in time require renewal under any circumstances.

In considering the question from a purely academic standpoint, the availability of the funds necessary for constructing the kind of surface required for any given case may be also assumed, so that the question of cost presents itself only as a factor of the problem, and not as a limiting feature of the selection. This assumption is necessary, because if sufficient money cannot be obtained, the question becomes one of the selection not of the proper surface, but of the best one that can be paid for; forming a somewhat different problem, with greater limitations. In fact, the entire question may be said to cover two classes of cases, namely, those which are not limited by some special consideration, such as cost, grade, etc., and those which are so limited. The latter class is more frequently met with.

The word pavement is used by the writer for any class of hard surfacing of the road or street.

Mr. A. T. Byrne, in his work on Highway Construction, names the following as the essential qualities of a good pavement: Imperviousness; durability; freedom from slipperiness, noise, dust and mud; adaption to every grade and to every class of traffic; ease of cleaning; minimum resistance to traction; cheapness.

Mr. G. W. Tillson, in the valuable chapter on "The Theory of Pavements" in his book on "Street Pavements and Paving Materials," appears to have originated the method of selection by assigning comparative values to the different qualities of surfaces upon a scale of 100, as follows:—

	Values.
Cheapness	14
Durability	21
Ease of cleaning	15
Light resistance to traffic	15
Non-slipperiness	7
Ease of maintenance	10
Favorableness to travel	5
Sanitariness	13

Mr. Tillson also gives, in his table number 51, a summary of the values of the various qualities which he assigns to different pavements, as compared with the full value in the ideal pavement. By combining the various values of the properties which are demanded to meet particular conditions this author shows how the selection of a pavement may be made. In speaking of the values as applied to various pavements, Mr. Tillson says: "It must be understood, of course, that the table is a general one; that much of it is based on the personal judgment of the author; and it will vary in different localities, even if the conclusions are agreed to."

Mr. Ira O. Baker in "Roads and Pavements," divides the qualities of pavements, and gives the relative values as follows, in percentages of the value of an ideal pavement:

	Values.	
Economic Qualities:		
Low first cost	15	
Low cost of maintenance	20	
Ease of traction	10	
Good foothold	5	
Ease of cleaning	10	—60
Sanitary Qualities:		
Noiselessness	15	
Healthfulness	10	—25
Acceptability:		
Freedom from dust and mud	10	
Comfortable to use	3	
Non-absorbent of heat	2	—15

Mr. Baker states: "The assignment of these numbers is wholly a matter of judgment, and different individuals will differ greatly as to the relative values to be

*Paper presented at the Tenth Annual Convention of the American Road Builders' Association, Philadelphia, Dec. 9-12, 1913.

given to each quality. Different values should be assigned to the same quality according to the attendant conditions. The application of these principles is likely to be complicated by the personal interests of the residents or property holders."

An indication of the values of the qualities of different pavements is obtained from the average of the values as signed in ten replies by that number of paving engineers to an inquiry by the United States Forestry Service, which are tabulated as follows, using standard values which are apparently based on Mr. Tillson's but differ slightly, viz:—

sidered. A certain tonnage in heavy slow-moving vehicles with iron tires produces an entirely different effect from that produced by the same tonnage in lighter rapid-moving automobiles with rubber tires; and a still different effect will be produced by the same tonnage in heavier and slower motor trucks. It has been well suggested that a traffic unit should be adopted, which could be used to represent, as far as possible in the same denomination, the amount of wear caused by the passage of one ton over the road in each of the several ways. The width of space available for travelled way must be considered in connection with the amount of traffic.

Comparative Value of Different Pavements.

Qualities.	Standard percentage value.	Granite.	Sand stone.	Sheet asphalt.	Asphalt block.	Brick.	Macadam.	Treated wood block.
Cheapness	14	4.0	4.0	6.5	6.5	7.0	14.0	4.5
Durability	20	20.0	17.5	10.0	14.0	12.5	6.0	14.0
Ease of maintenance	10	9.5	10.0	7.5	8.0	8.5	4.5	9.5
Ease of cleaning	14	10.0	11.0	14.0	14.0	12.5	6.0	14.0
Low traction resistance	14	8.5	9.5	14.0	13.5	12.5	8.0	14.0
Non-slipperiness	7	5.5	7.0	3.5	4.5	5.5	6.5	4.0
Favorableness to travel	4	2.5	3.5	4.0	3.5	3.0	3.0	3.5
*Acceptability	4	2.0	2.5	3.5	3.5	2.5	2.5	4.0
Sanitary quality	13	9.0	8.5	13.0	12.0	10.5	4.5	12.5
	100	71.0	73.5	76.0	79.5	74.5	55.0	80.0

*Acceptability includes noise, reflection of light, radiation of heat and emission of odors, etc.

The prime factors which should determine the selection of a type of surface, when this selection is not limited by any necessity for giving undue preference to any factor, appears to be as follows:—

1. The volume and nature of the probable traffic over the pavement.

2. Conditions incident to the location of the pavement; including the character of the adjacent land and improvements; the character of the foundation; the kinds of adjoining pavements; the ruling gradients; the climatic conditions; and especially the availability and cost of different materials at the work.

3. The characteristics of the surface which will adequately meet physically, hygenically and esthetically the conditions expressed in the two factors first named. These characteristics are practically those named in the tables cited.

4. The quotient obtained by dividing the total estimated traffic to be carried per unit of width into the cost per unit of area of the pavement during its probable life; including first cost and interest on the same; special surface treatment for dust suppression or other purposes; and any necessary repair until replacement; but not including the cost of cleaning. For the best pavement this quotient will be the lowest. This ratio may be called the ultimate cost of the pavement per traffic unit carried.

(1) The volume and nature of the traffic—not the present traffic, if the road now exists, but the traffic after the improvement—is the most essential factor. This must necessarily be approximated, and due allowance should be made for increase during the life of the pavement. The effect of traffic upon the pavement should be expressed in units of a known value, to which all classes of traffic can be reduced.

The different effects produced on a surface by different kinds of traffic are elements which must be considered. Traffic when confined to a single vehicle width is very damaging and widening a few feet only may easily double or triple the life of a pavement.

One solution of the character of the roadway, when pleasure traffic and commercial vehicles use the same highway, is to construct a surface adapted to each, separated by a short distance, making a double roadway. This is done to the great advantage of the road users of every class where the travel is sufficiently dense to require it. It is customary, for the reasons indicated, as well as from and esthetic standpoint, to prohibit heavy traffic on roads built especially for pleasure drives. This factor of traffic, which is one of the most essential, is sometimes given the least consideration, and we occasionally hear of a county or township bonding itself for a costly form of surface where a gravel road would answer the probable demands for some time. On the other hand, in the neighborhood of cities, where the travel is already heavy and sure to increase, roads or pavements are frequently laid which are inadequate for even present conditions.

The nature of the future traffic is quite as important as its volume; although owing to rapid changes in the weight and speed of freight-carrying trucks, and the increase of motor-driven vehicles, this is difficult to forsee. An estimate of traffic on a city street made for thirty years hence would probably almost ignore horse-drawn vehicles, and would provide for the heaviest class of motor-trucks instead. If the traffic is to be of one class only, such as motor vehicles driven for pleasure with a moderate limit of speed, the problem is much simplified, and it is the writer's experience that no class of traffic is more easily or cheaply provided for. If there is to be a mixed traffic of horse-drawn vehicles, motor trucks, and other automobiles, with a possibility of the steam-lorry and train of wagons in the future, this combination will require a very strong and durable pavement, and first cost should be given little consideration.

There is an approximate limit to the amount of tonnage which can pass over any width-unit of pavement in a given length of time; and any amount of traffic approaching this would demand the very highest type of surface practicable to be constructed. This limit is probably seldom reached for more than a few hours daily on the heaviest travelled streets.

(2) The nature of the surrounding conditions is a potent factor in determining the character of the surface. In a manufacturing or wholesale district where noiselessness is less essential a granite or brick block may well be used on account of its strength or durability; whereas in a residential section the less durable but more quiet asphalt or wood block is better. In a farming or country area, a macadam or gravel road harmonizes more perfectly with the surrounding fields and woods.

The value of the adjacent property has a large bearing in the case, for it is the basis of the revenue which usually must be raised to pay for the improvements. A closely built city block can fortunately afford a much higher priced pavement than a less closely built suburban section, on account of its larger taxable value.

The character of the foundation governs the construction in many cases. An especially soft sub-grade may require a base of cement concrete; while, with certain types of pavement, upon hard ground, this might be omitted at a considerable saving of cost. If the problem be that of surfacing an old waterbound macadam roadway, it may be solved by using a surface, for instance, of bituminous concrete, placed directly upon the old macadam; whereas, if no such foundation existed, an entirely different type of pavement might be required. A rigid surface, such as one of cement, should never be placed where there is danger of settlement.

The ruling gradients of the road must be considered, for the reason that some pavements do not afford sufficient foothold upon steep grades, and the climate must be taken into account, since pavements are differently adapted to warm or cold or wet or dry conditions. The character of adjoining pavements will have weight with the engineer, except in cases where the requirements are very exacting. Again, the practical consideration as to the availability of contractors and suitable construction plants in the vicinity must have weight as entering into the price to be paid.

Among local conditions, the availability of material, either local or foreign, the use of which latter largely depends upon the cost of transportation, is probably the deciding factor in more cases than any other. A city in an area producing excellent paving brick would be unwise to import granite block from a distance at a heavy cost for freight; or even to pay too heavily for the transportation of asphalt, and a western country could by no means afford to pay the cost of transporting the trap-rock used so largely on roads in the east, but must find the solution of its problem in the use of a surface of cement concrete or other material produced nearby. The very possibility of the construction of any roadway whatever, in many cases where the funds are limited, is dependent upon making the best possible use of the local materials available.

(3) The characteristics of the surface to be constructed, which must satisfy the requirements of the traffic, the environment, the foundation, the gradients, and the climate, may be divided into three classes, viz.:

(a) Those which are purely physical;

(b) Those which are required for health;

(c) Those meeting requirements of a more or less esthetic nature.

(a) The physical requirements are those previously stated, viz.: Strength; durability; ease of traction; sufficient roughness when either dry or wet to prevent slipperiness; imperviousness to a greater or less degree; sufficient smoothness to render the surface easily cleaned and to prevent excessive jarring of vehicles passing over it at high speed, and facility of repair, both as to openings and as to wear of the surface.

(b) The requirements as to health include noiselessness, freedom from dust produced by the wear of the wear of the pavement, and heat-absorbing and heat-radiating quality in a minimum amount.

(c) The esthetic requirements are such as appeal more directly to the senses. These are harmony with surroundings, a pleasing appearance, extreme noiselessness, and almost absolute smoothness. These qualities in their highest degree are usually demanded only in connection with streets of the highest class, or with pleasure drives.

Examining these characteristics further, but without going into details as to the qualities of materials, we find as follows:

Imperviousness is a very important feature, both from a sanitary standpoint, and as a matter of increasing the durability. No very permeable surface can be considered a good one.

Smoothness is particularly demanded by motor-vehicles, especially where speed can be used. Non-slipperiness is produced by slight irregularities in the surface. It is necessary for good foothold and to prevent skidding of rubber tires when the surface is wet.

Facility of repair is essential; and for this reason the pavement should not be constructed of materials and by methods which will be difficult to duplicate after the completion of the original pavement, without at least providing for its repair. Block pavements lend themselves most easily to repair, since they require no large plant for that purpose.

The sanitary requirements are mostly for the benefit of the public living or working on the streets, and less for the road-user. A noisy pavement with much travel seriously affects the nerves of those near it; a dusty pavement permits fine grit to be carried into eyes and lungs and becomes a muddy pavement in wet weather. A heat-absorbing and heat-radiating pavement, such as sheet asphalt, if exposed to the sun, adds much to the temperature of the street and the surroundings in the hot weather, to the discomfort of all in its vicinity.

The esthetic requirements are such as add a touch of good taste, and perhaps of luxury, to the road and are increasingly in demand.

All of these requirements will have somewhat different weights in different cases. Some of them can be omitted in considering nearly every case, and must be omitted often. In view of this it seems best not to assign special values to these requirements; but in each case to give preference to such characteristics as the situation demands, and to use the surface combining these characteristics in the greatest degree.

(4) This combination must produce a pavement, usually, which will give the lowest ratio of total cost to the total traffic units to be carried. The surface thus chosen should be that which is best adapted to the purpose.

In instances in which a high first cost might be prohibitive, the pavement showing the lowest cost-tonnage ratio could not always be selected; and a less costly surface with a higher rate of maintenance would be necessary.

The process of selection will usually be one of elimination, thus for a certain case of proposed construction several well-known classes of pavements, of nearly equal theoretical value, will be considered; say, granite block, vitrified brick, wood block, and sheet asphalt. If low cost is paramount, this element may eliminate the granite block and the wood block; and if noiselessness is desired, the vitrified brick will be eliminated; leaving the sheet asphalt, or a similar surface, to be adopted. If durability alone is considered, the granite block might be chosen where this material is convenient; whereas, if the case demanded noiselessness, smoothness and durability in a high degree, without especial reference to first cost, the wood block would probably receive the verdict.

A resident paving-engineer familiar with the local conditions and with pavements in general often need not tabulate or even assemble, otherwise than mentally, the reasons for his choice, and this mental way is very often the method of selection employed. In such cases, however, the same conditions should, and do, actually control as would be the case if the situation were being considered for the first time with the utmost pains.

In order to proceed with system in the matter of choice of a new pavement, or one in a new location, the engineer should have the necessary data as to traffic; as to cost of construction and maintenance of similar pavements in the vicinity, or under like conditions; as to the life of such pavements; as to climatic conditions, and, in fact, all available information on the subject. It is unfortunate that the supply of information on the subjects is not what it should be. This is a defect which every highway engineer can aid in correcting, by careful investigation and records in connection with his work. In the absence of the necessary data, the selection is merely an assumption based on judgment and experience, and sometimes on a desire to experiment, and this is the manner in which the choice is very often made.

On the whole, the selection of a pavement, like the tariff, is largely a local question, and in its final aspect, when under practical consideration, presents such a number of features, some of which are predominant at one time and some at another, that each case must usually be considered alone.

The matter is well summed up in this quotation from Mr. Tillson: "The official who decides on the material after the most careful investigation will often find that his decision is displeasing to many people. . . . . He must make his decision after taking all things into consideration, and stand by it although it will not always prove satisfactory to all. . . . . But if he meet the question successfully, and ultimately arrive at the true solution, his satisfaction is as great, perhaps, as in any other branch of his profession."

The reason why oil paint will not stand well on concrete surfaces is that the oil is saponified by the free lime of the cement. It is stated in a French architectural journal that this drawback can be obviated by first applying a wash of zinc sulphate in the form of a 1 : 5 solution, the result being to produce a film of plaster and zinc oxide which is quite harmless to oil.

THE SELECTION OF A ROAD SURFACE.

Discussion by W. A. McLean, Commissioner of Highways for Ontario.

THE paper by Mr. Grabill on "Factors Governing the Selection of a Road Surface or Pavement" is a most interesting and illuminating contribution. It expresses the complexity of the modern problem, which at times confronts road authorities.

Traffic.—Whatever other factor may enter into the problem, roads should be built to suit the traffic, using available materials to the best advantage. To do this, requires a thorough knowledge of (1) the traffic, and (2) the material. A paper read before this association last year by Col. Schier, of Massachusetts on "Traffic Census" is one of the most noteworthy statements on this phase of the subject yet produced, and is a type of analysis of which we have great need.

Knowledge of Material.—Traffic on the public highway within the past decade has so radically changed, that our knowledge of the characteristics of materials in meeting the new requirements is proportionately limited. A paving material should be in general use for at least its estimated lifetime before the facts regarding it are, to a reasonable extent, at our disposal. The mass of facts which we possess regarding any proposed material is an important factor in selection.

The elementary materials actually in use in road-building are comparatively few—such as broken stone, gravel, sand, clay, asphalt, tar, oils, vitrified brick, creosoted wood, stone setts, Portland cement—but their combinations and variations are almost innumerable. Unless some entirely new material comes above the horizon, the next five years will be a striking era, in leading to the more effective use of the materials now available, in confirming or setting aside our opinions of to-day and in standardizing construction. So far as roads of the open country are concerned, of which I am more especially speaking, there is a vast amount of theory still to be tested.

Division.—A road or pavement may be conveniently divided, for consideration, into four parts: (1) The system of drainage; (2) the earth sub-grade; (3) the foundation, and (4) the wearing surface.

As a rule, the wearing surface necessary will dictate the character of the substructure. But in other cases, one or more necessary or existing features of the substructure will influence our choice of wearing surface.

Foundations.—A secure foundation is an absolute necessity for permanent bituminous coatings. To this end a substantial depth of foundation should be used, a condition with which roads on this continent have not always complied. Very few conditions of heavy or constant traffic can be successfully met with a less foundation than 6 to 9 inches, or a less total depth of stone in the road crust than 10 to 12 inches. The price of good roads in one particular, at least, is a substantial depth of stone. The difficult part of our problem, the financial aspect, is not so much the selection of a wearing surface as our ability to pay for strong foundations. The existing foundation, or local materials available for a foundation will frequently dictate what the surface should be.

Heavy motor trucks and busses are placing a great and unexpected strain on road foundations. On main roads leading out of London, England, old 6-inch concrete foundations are being torn up and 9-inch foundations

put in their place. This is necessitated by heavy and constant motor-bus and traction engine traffic.

New Bituminous Coatings.—In Great Britain, France and other countries of Europe, bituminous treatment has largely become the accepted practice in meeting the requirements of motor traffic in the open country: By carpet coats; by grouting or penetration; and by mixing methods, according to local conditions. It need not be said that asphalt and tar are now, on this continent, being used with marked success—a result that has been reached after many trials and not without tribulation.

That bituminous paving has been markedly successful in England is probably due, to a large extent, to the fact that it has been commonly applied only on old, solid and well-settled foundations, in re-surfacing their old macadam roads. Many of the failures on this continent, on the other hand, have plainly been due to weak, badly-drained foundations. To uneven settlement of new roads under traffic may be attributed much of the failure of bituminous surfaces, rather than to any inherent defect in bitumen itself for road purposes.

Settlement of New Roads.—Roads, as we now build them, are rolled in several layers with a ten- or twelve-ton roller, giving a compression of 500 lbs. per inch. Traffic follows with tire compression up to 700 and 800 lbs. per square inch. Under succeeding wet conditions of fall and spring, settlement must inevitably occur, leading to an uneven, wavy surface and consequent decay.

In the speaker's experience, a broken-stone road, commonly does not reach final settlement for two or three years after first construction; but within that period permanent subsidence may be taken for granted. French, German, and English road-builders laying bituminous surfaces over their old roadbeds, are manifestly not dealing with a condition which commonly exists here.

A reasonable course to pursue in many cases would be to build waterbound macadam roads on Telford or other suitable foundation. The surface could be maintained for two or three years by thin paint coats or oiling. At the end of that period perfect settlement and stability of the foundation having been attained, a heavy and durable bituminous surface could be applied where traffic demands it.

Concrete Roads.—The prejudice against concrete roads has within the past couple of years, been largely broken down, and a good deal has been done to demonstrate their value when built under favorable conditions; indicating more especially a one-course mixture; a high proportion of cement; a clean, tough aggregate; a flat undersurface; joint protection, and good drainage. A number of experimental sections have been built by the Ontario Highway Office, under varying conditions.

So much may be hoped, that there is a temptation to prophesy, but adhering to a strict basis of proven fact, and in the light of our knowledge of concrete in other structures, it is conservative to say that the next few years should be fruitful in determining the place of this important material, in the field of roadmaking; in putting the facts at our disposal to determine when and how it can be used with economy and certainty of results.

HIGHWAY IMPROVEMENT IN SASKATCHEWAN.

THAT the good roads movement is taking as firm hold in the west as in the east is evidenced by the very progressive manner in which their improvement has been undertaken by the various provincial governments of the western provinces.

The first annual report of the Board of Highway Commissioners of Saskatchewan for the year ending Feb. 28th, 1913, shows a very creditable advance in that province. The board derives its power from the Provincial Act respecting the construction and improvement of public highways, March 15th, 1912, and consists of three members appointed by the Lieutenant-Governor-in-Council, together with an advisory committee of two to be called upon when required by the chairman of the board.

Immediately following the passing of the Act, an appropriation of $1,500,000 was made by the assembly, and this amount, together with $100,000 with which the Public Works Department were to have carried on the erection and repairs of steel bridges was placed at the disposal of the Board of Highway Commissioners. This made a total of $1,600,000 available for roads and bridges, $1,300,000 of which it was decided to spend on the former.

Three main points, according to the report, were kept constantly in mind in determining the distribution over

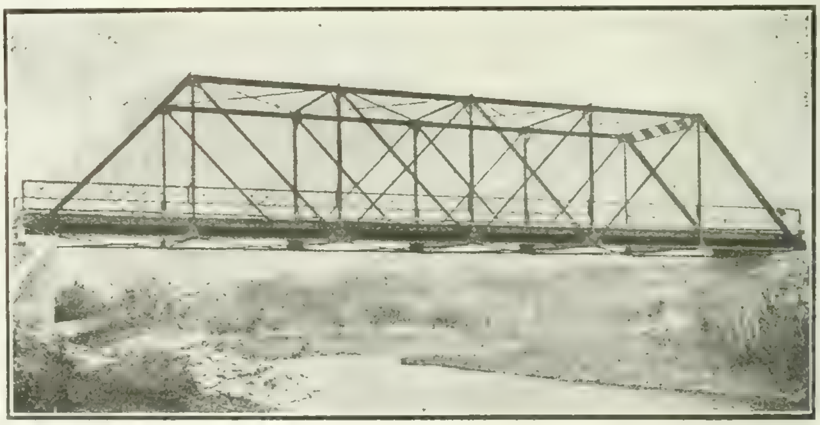

Fig. 1.—A 100-foot Steel Span on Concrete Abutments Over Eagle Creek, Sask.; Typical of the Steel Highway Bridges of the Province.

the province. First, a schedule was prepared whereby each municipality could receive $5,000, or each constituency $30,000. Then, main or trunk roads having the heaviest traffic, and feeding large areas were to have preference. Lastly, assistance would have to be given to many places in the province "where improvements were urgently required, which, although not on roads classed as main roads, were so far beyond the means of the local authorities" that government assistance would be imperative. This last applies to bridges and long side-hill roads across ravines and valleys, fills across large sloughs, marshes, etc. It was necessary, of course, to deviate considerably from the rule of only giving $5,000 to a municipality, but this rule was kept in view, and by it a fairly equitable distribution was obtained.

To thoroughly familiarize themselves with existing conditions, and to decide where improvements were most necessary, the board enlisted the help of inspectors, muni-

cipal councillors, and others; and thus succeeded in obtaining a great quantity of information by which they were enabled to start working out a main road system for each municipality in conjunction with adjoining systems. An effort was made to induce each municipal council to decide on what should be the main road system within their boundary, and in this they were assisted in every way possible by the board.

To hasten the commencement of the work so that the assembly's programme might be carried out in 1912,

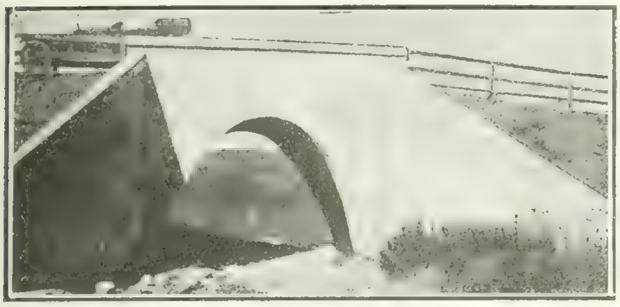

Fig. 2.—A 20-foot Concrete Span Over Gibson Creek, Sask.

a bulletin giving the board's aims, together with various methods of road construction, was widely disseminated throughout the province. To induce the municipalities to co-operate a set of regulations was adopted whereby each municipality could be assisted each year to the extent of 50 per cent. of the cost of any improvement they wished to make, subject to the restrictions in the regulations, some of which are noted below.

The assistance in any case is not to be more than the amount previously mentioned ($5,000). This applies to road construction, and not bridges. The improvements must be of a permanent nature, and such as may suitably be paid from capital account, and the construction must in every way be satisfactory to the board. A rather interesting clause is to the effect that the board have power to valuate any work, in their opinion costing too much,

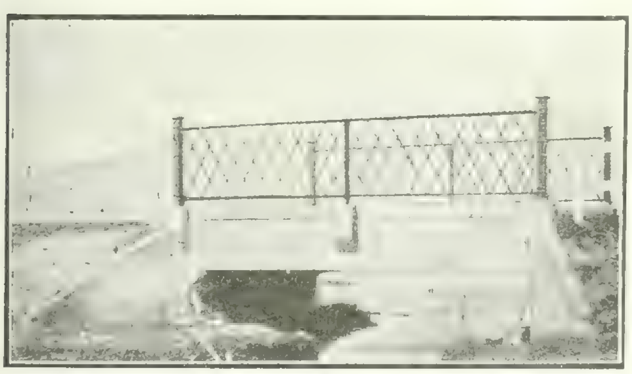

Fig. 3.—A 20-foot Concrete Span Over Rosthern Creek, Sask.

and pay the grant accordingly. To induce the local authorities to properly care for the roads when constructed their condition will be considered in giving further assistance.

Besides the distribution of bulletins of useful information on road making and actual help in construction, experiments have been made with the idea of overcoming special difficulties. So far nothing very definite has resulted from them, but they have served to indicate lines along which success may be possible, and it is probable that before long some method may be devised whereby the unfitness for earth road making of many of the gumbo clays throughout the province may be overcome.

By addition of the tabulated lists in all 363 roads were worked upon by government road gangs during the year, and 145 rural and urban municipalities received government assistance outside the regulations of the Board of Highway Commissioners. The amount expended directly on road improvements was $1,025,958.66. By direct grants to municipalities $100,935.54. By municipalities under the regulations, $138,325.87. Bridges departmental staff, inspection, printing, etc., cared for the balance of the appropriation.

Bridge Work.—The following summary of the bridge work is of interest. In all 19 steel and 2 concrete spans were constructed as follows:—

Construction.	Number of spans.	Length of span.
Steel	1	250 feet
Steel	2	150 feet
Steel	3	126 feet
Steel	4	100 feet
Steel	5	80 feet
Steel	3	60 feet
Steel	1	40 feet
Concrete	2	20 feet

The 250-foot span is over Battle River west of Battleford, and is a Pratt truss with curved top chord. The steel was supplied by the Canadian Bridge Company, of Walkerville, and erected by R. J. Lecky Company, of Regina, who erected the steel on twelve of the nineteen spans mentioned above. The departmental crews erected the steel for five, and Mr. E. Lenkin, contractor, the sixth. (There is one steel bridge to be erected.) The Hamilton Bridge Company supplied the superstructure for nine, the Western Steel and Supply Company for five, the Sarnia Bridge Company for four, and Wm. McNeil and Sons, Nova Scotia, for one of the 126-foot spans. The two 20-foot concrete spans were erected by

Fig. 4.—Typical Side Hill Grading, Saskatchewan.

J. J. McDonough, who also was the contractor for the abutments of two steel spans.

If the Saskatchewan board continues as it has begun a great future may be predicted for roads in that province, and if, as the chairman, Mr. A. J. McPherson, anticipates, it will be able to co-operate with the other provinces in a coast-to-coast highway and also highways to other points of importance in Canada, a great boon will not only be conferred on each province but the country as a whole.

WATER POWERS IN MANITOBA

IN January 1st issue of *The Canadian Engineer* a reference was made editorially to a report submitted recently by Hon. W. J. Roche, Minister of the Interior, to the Public Utilities Commission of Manitoba, respecting the physical features of the water powers within the province. The engineers of the Water Power Branch, under the direction of Mr. J. B. Challies, Superintendent, have been making a systematic study of water power and stream flow throughout Manitoba. The report shows, in result, the power possibilities of the various rivers. The following information is derived from Mr. Challies' letter of transmittal to Judge H. A. Robson, Chairman of the Commission.

As stated last week, the main sources of dependable power in commercial quantities are the Winnipeg River, the Grand Rapids on the Saskatchewan River, the Churchill, Nelson, Berens, and others of the larger rivers of the north.

The first of these, the Winnipeg River, with its tributary, the English River, lies within easy transmission distance of the present commercial centres of the province. It can furnish an adequate supply of hydro-electric power to satisfy all anticipated power requirements of the present settled communities.

Such a statement as this possesses a degree of attractiveness that will readily be embraced by the various power-using industries of the province. The development of an adequate supply of dependable water power, in the face of an alarming and constantly increasing price of coal for steam production, combined with the scientific progress that has been made in the manufacture of power generators, transmission apparatus, and equipment for economical consumption of electricity, unite to endorse unhesitatingly authoritative steps to increase the industries at present in operation or under contemplation. To this should be added the demand for hydro-electric energy for transportation and municipal enterprises, such as are springing up in and around the city of Winnipeg, and which have made the question of power development on the Winnipeg River one of the most important administrative matters that is occupying the attention of the Department of the Interior. Fortunately a well-considered and cautious policy of water power administration has been determined upon, and regulations put into force which afford every reasonable protection to the public in the way of limited grants, rentals and control of rates, both subject to periodic revision, and at the same time providing sufficiently attractive opportunities for investment to actively interest the capitalist.

Consistent with the policy of the Dominion Government, the Minister of the Interior has instructed that all vacant Dominion land contiguous to power sites on the Winnipeg River, or any other river in Manitoba, be reserved for disposition only under the water power regulations referred to.

It was early found necessary, in connection with the consideration of sundry applications for power privileges on the Winnipeg River in Manitoba, for the Water Power Branch to have extensive power and storage studies made of that portion of the Winnipeg River within the province of Manitoba. These investigations show that at eight distinct power sites, by means of storage easily and cheaply accomplished at the Lake of the Woods, at Lac Seul and at other lakes in the province of Ontario, it is possible and economically feasible to develop over 409,700 continuous 24-hour horse-power all within 80 miles of the city of Winnipeg and within feasible transmission distance of all commercial centres of the present settled portions of the province.

Of the eight possible power sites on the Winnipeg River there are three now under development, representing a total power capacity of 199,000 24-hour horse-power. One site is completely developed by the Winnipeg Electric Railway Company on the Pinawa Channel, and produces about 26,500 h.p. under most favorable conditions. Another site at Point du Bois Falls, developed by the city of Winnipeg, produces at the present time about 20,800 h.p., but is capable of extensions to a maximum of 77,000 24-hour horse-power. Development at the third power site at Great Falls, having a maximum possible development of 95,500 24-hour horse-power, is about to be commenced.

There is, therefore, at the present time about 47,300 h.p. produced on the Winnipeg River, and transmitted for use in and around the city of Winnipeg, which can with the two present plants be increased to 103,500 24-hour horse-power.

The five remaining power sites on the Winnipeg River are under the control of the Dominion Government, and can furnish a further amount of 24-hour power to a maximum extent of 210,700 h.p. In addition there are several important power sites on the Winnipeg and English rivers within the province of Ontario, which are within easy transmission distance of Winnipeg.

It is interesting to note that the Winnipeg River in its natural condition forms one of the most notable power rivers in the world, having a total drop in the province of Manitoba of 271 feet, and in average years its maximum flowage being only about four times its minimum—about 12,000 c.f.s. Full information regarding the enormous potential power resources of the river is set out in detail in the report by Mr. J. T. Johnston, Hydraulic Engineer of the Water Power Branch, under whose direction the surveys and investigations of the branch have been carried on.

With respect to the rivers in the far North, it is stated that the power possibilities associated with them will be of great importance to the future development of this portion of the province, although little is known of them at the present time, the only available data being from reconnaisance surveys. However, the data is sufficiently reliable to indicate that enormous amounts of dependable power, capable of economical development, are there.

With the exception of the information in the report relating to the Winnipeg River the preparation of the material was commenced by Mr. Douglas L. McLean, then chief engineer of the Manitoba Hydrographic and Power Surveys. Since his resignation in October, the work has been carried on by Mr. S. S. Scovil, assistant engineer, to whose energy and resourcefulness Mr. Challies, in his letter, pays tribute for the compilation of the material in the short time available.

The Fort William plant of the Canadian Car and Foundry Company will be in readiness to operate about May 1st. As to whether it will be started up immediately upon the completion depends, of course, upon the abundance of orders for cars, but it is altogether likely that the plant will not delay in getting into operation.

WOODEN STRUCTURES.

By J. A. Macdonald, Ottawa, Ont.

In a great forest country like Canada, wood, as a material for the construction of viaducts, bridges, trestles, etc., can frequently be selected in preference to stone, cement or steel, on the score of economy; and also owing to the comparative rapidity with which such structures may be erected. Wood is, of course, very inferior to these other materials as regards strength and durability, and in construction work the inherent defects of wood must be counteracted as fully as possible. Experience has shown that the most simple combinations of timber are superior for strength to complicated systems, and the latter have become almost entirely abandoned. By calculation, a scientifically framed truss may be made, but the impracticability of making such a perfect assemblage of the timbers as the calculations would have been based upon, renders such complicated combinations unwise. Moreover, to obtain even that degree of perfection of which practice is capable, we must resort to an excess of strapping, bolting, keying, mortising, and jointing of every description, which becomes very expensive, and when we have done all this, the destructive effects of rain, sun and wind increase in the very proportion of complication embodied in the system of construction. Besides, also, an unavoidable quantity of moisture is wasted, which might have properly been reserved for an increase of strength under a more simple mode of treatment. The intention of a truss, composed of a multitude of timbers, is not only an equable distribution of the superimposed weight, but also a dispersion of the shaking and vibration resultant from the motion of weight. Nothing but the very best workmanship must obtain, and we all know how extremely difficult this may be, however great the expense incurred.

The Mortise and Tenon.—A few words on details may be of some service to the reader. Timbers are connected by various types of joints, the most simple being generally the best. Fig. 1 shows a tenon and mortise. The thickness of the tenon, *T*, is made, according to the best engineering authorities, one-third the thickness of the timber on which it is cut, and the size of the mortise, *M*, corresponds to the dimensions of the tenon. The depth of a mortise should exceed that of the tenon by a small amount for a more perfect joint. The shoulders of the tenon should be exactly in line, and perpendicular to the axis of the timber. When acting by suspension, little depth is required if a strap be added; an oak treenail should be driven through the timbers, the holes being bored after the tenon is in the mortise. The diameter of the treenail should be, according to Colonel Emy, "one-quarter the thickness of the tenon, and the hole bored for its reception should be two-thirds from the end of the tenon," as shown in the figure; but the value as regards the strength of a tenon and mortise should be independent of the treenail. This is for a rectangular mortise and tenon. Fig. 2 shows an oblique joint of this description, and is self-explanatory. The above description of joint, though common, is not the best kind, the timber, T, being weak at the point, *a*, and liable to fly. Fig. 3 is a better system, where *T* is partly joggled into *M*, and *s x* is made of from about one-fifth to one-fourth of the thickness of *M*.

In setting out a joint of this kind, with a single joggle and no tenon and mortise, to find the direction of *s x* (Fig. 4) draw the central axis of the timbers, and *o s* will give the direction of *s x*. Or, divide the angle *a s b*, and the line *s v* will give the direction *s x*. Another method is to make *s x* perpendicular to *s b*; and another, from *c* as a centre with a radius *c s*, describe an arc, on which set off from one-fourth to one-fifth of the thickness of the timber *M*. It must not be forgotten that too sharp an angle at *x* is likely to make *M* fly at *x*.

Scarfing.—It is always expensive to obtain timbers of large scantlings and great length, and when a beam of 24 feet or more is required, we have generally recourse to scarfing which, it is unnecessary to add, is a joint in which the ends of the timbers are cut and overlapped so as to present a uniform appearance. Some are partial to complicated scarves, but there should be no greater faith in them than in complicated trusses, much for similar reasons, and because so much hacking of the timbers must weaken it. Moreover, they become very expensive.

In a scarf it is evident that the bearing surfaces have to support the strain, and therefore the greater the quantity of surface the greater the strength, provided the best form be given. Therefore, a long scarf is stronger than a short one, for the same reason that any strength at all is gained by a scarf, but a great waste of timber and much workmanship involved. One important consideration, and which should never be lost sight of, is the strain to which a scarf will be exposed, compression or tension.

Fig. 1.

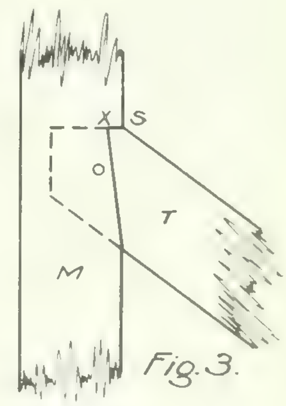

Fig. 3.

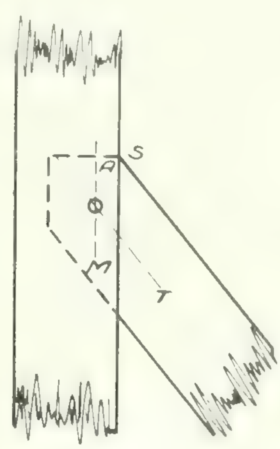

Fig. 2.

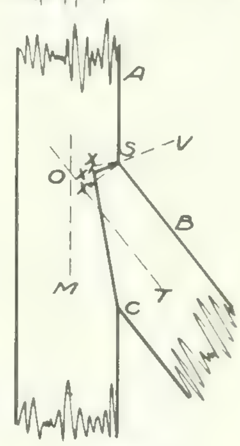

Fig. 4.

Scarves are greatly strengthened by iron bolts and oak keys. Where the surfaces of the scarfing are square, iron bolts are preferable to keys. The contrary is true where the jointing surfaces are oblique to the fibres of the wood. Let Fig. 5 represent a beam scarfed at *W*, where it is exposed to a strain from the weight at *W*. The

upper portion of the beam is exposed to compression. The rectangular bearing, a, is therefore the most appropriate, as an acute angle formed by a line parallel to b, would, on the beam being compressed, act like a wedge, and tend to make the upper portion of one beam fly. But this is reversed at b, which point would tend to open by tension. Of the keys, c and d, the first would be under compression, and the latter would be loosened. Being near the neutral line, the tightening and loosening would be comparatively small, unless the beam were loaded beyond its safe bearing strength. Also c, under compression, would tighten the beam *a*, and though *d* would not do the same at *b*, the bevel joint must prevent any evil results. Whether we have one, two or more keys, the single or aggregate depth should not exceed the depth of the beam. Neither should they be too violently tightened when driven. This scarf is short and considerable strength may be added by a bolt at *W*. It would be better still to place a bolt at *c* and at *d*, with the key in the centre, as in Fig. 6.

Fig. 7 is strong enough for most purposes. It need scarcely be observed that the further the scarf may be

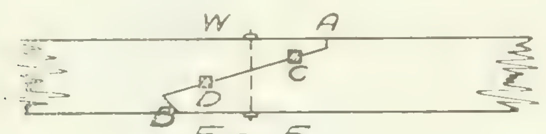

Fig 5

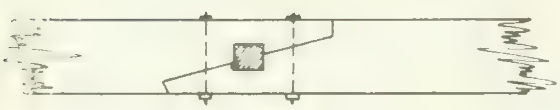

Fig 6

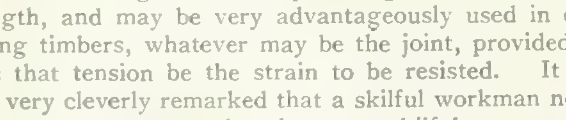

Fig 7

from the points of bearing, the greater the strength required. Bolts should never be placed too near the end of a beam. Wrought iron straps are great auxiliaries of strength, and may be very advantageously used in connecting timbers, whatever may be the joint, provided always that tension be the strain to be resisted. It has been very cleverly remarked that a skilful workman never employs many straps, but however skilful a carpenter may be, he cannot prevent the effects of atmospheric influence; neither can he give to comparatively new wood the properties of well-seasoned timbers. No man who knows anything about designing in wood, would consider straps as factors of strength in his construction work, but simply as fastenings and auxiliaries. They are perfectly admissible, of course, in moderation, and are becoming daily more in use. Before use, straps, and indeed all iron work, should be heated to a blue heat, and struck over with raw linseed oil. This is much preferable to paint as preventative from rust. A strap 1 inch wide may be made ¼ inch thick; 1½ inches wide, ⅜ inch thick; 2 inches wide, 7/16 inch thick.

Cast iron plates and shoes are also very useful to receive or to equalize the thrust from the ends of butting timbers; the first particularly where employed as a connecting surface between the ends of timbers, which from shrinkage, defect of workmanship, or otherwise, may come to bear upon opposite angles, instead of the whole area of their intended connected surfaces.

Wooden Piers.—As regards piers, too much depends on circumstances connected with the nature of the natural foundation to recommend any particular plan. According to these circumstances, it may be advisable to build entirely of wood or of masonry and wood. It must not be forgotten that wood exposed alternately to wet and dry cannot last long, and this, therefore, is one reason for employing stone or concrete in water or marshy ground. On the other hand, in weak ground wooden piers are preferable, and sometimes it may be advisable to make a wooden pier occupy an area of considerable extent, in order to spread the effect of a superincumbent weight over a greater surface; and thereby, to a certain degree, neutralize this effect. Such may be the case in working over ground that is peaty to any considerable depth.

To Ascertain the Cohesive Strength of Timber.—The tension that timber will bear, when the force acts in the direction of the axis of the timber may be calculated by multiplying the area in inches by the proper "tabular number" from a table of specific gravities. For example, to find the force that will tear asunder a piece of 4-in. by 4-in. fir, we have an area of 16 square inches, and the tabular number is given as 9500; thus $9500 \times 16 = 152,000$ lbs., one-fourth of which would be taken in practice for a perfectly safe load.

Given the load, the size of the scantling may be calculated by reversing the method.

Not long since the River Euphrates was diverted from its new course at Hindlieh, where the firm of Sir John Jackson (Limited) have recently completed the first great barrage in connection with their extensive Tigris-Euphrates irrigaton works. This is a part of Sir William Willcock's scheme upon which the Turkish Government originally proposed to expend some twenty millions sterling. The whole operation of turning the river into its new course passed off most successfully. The river was diverted by a dam, held up by a barrage, by means of which the water can be distributed through a regulator down the old Hilla branch past Babylon to ancient Hilla. The barrage was built to the east of the river bed. It is 800 feet long, and consists of thirty-five arches fitted with sluice-gates, each sixteen feet wide. The piers are nineteen feet high and four feet thick and the key-piers eleven feet. They rest upon a foundation of three feet of concrete and six feet of brickwork. The barrage will raise the level of the water twenty-two feet. Another barrage has been built immediately below the upper Hindlieh barrier. This was a perfectly straightforward bit of work, consisting of a lock and a huge shelf of masonry. By these means a dam of 130 feet thick has been flung across the river, which is 520 feet wide at this point, and the water turned into the new bed. When all these works at Habbania and Hindlieh are complete, with the smaller irrigation canals, some 600,000 acres of land will receive a plentiful and constant supply of water; and the ancient problem of the Babylonians will have been solved by British engineers.

WATER MUNICIPALITIES IN BRITISH COLUMBIA.

Legislation is being planned in British Columbia for the establishment of municipal organizations to control the conservation and distribution of water for irrigation purposes. If the bill which will shortly come before the provincial legislature becomes law, farmers in the dry belts will be in a position to co-operate in the operation of irrigation systems. It will make possible the joint ownership and control of irrigation enterprises in any locality where the lands are so situated that they can be irrigated from a common source and through a common system. Such a bill will affect considerably the Okanagan, Kamloops, Southeastern Kootenay, and Ashcroft districts.

This bill for the formation of water municipalities is the logical sequence of the revision and consolidation of the Provincial Water Act, which revision was completed last November. The complicated subject of water legislation, although established in British Columbia to a degree that has drawn praise and compliment from prominent irrigation authorities, has experienced a severe handicap in the loose methods of administration that naturally prevailed in the earlier history of the province. The efforts to bring water records up-to-date has uncovered numerous vagaries and clauses uncertain in meaning. Dissatisfaction among water holders brought about the passing of the Act in 1909, and the appointment of a board of investigation. The duty of this board has been to determine existing rights to the use of water in various streams. The making of satisfactory adjucations has required careful surveys and the compilation of accurate hydraulic data. Points for investigation included the minimum and maximum supply and consumption at different periods of the year; the capacity and safety of storage works, the points of water diversion, the lines of canal, the individual points of distribution, and the nature of use.

This work is well under way, and the board of investigation has already held numerous final hearings on many streams where conflicting rights have been for years the subject of warm dispute.

The proposed bill contemplates the expropriation of all private water systems. It will, however, leave the actual water rights on streams standing in favor of the individual owners, the water municipality simply acting as carrier and conserver. The municipality will have government assistance in the formation of its organization and in its preliminary survey and hydrographic work. Its boundaries are to be fixed by the government upon the advice of the investigating board, each district to take care of all the agricultural land within those boundaries that is adaptable to irrigation.

MONTREAL'S INEVITABLE WATER INVESTIGATION.

The catastrophe which befell Montreal toward the close of 1913 will long be regarded by its citizens as unparalleled in the history of any Canadian city. Regretably the civic finger of censure is levelled at its engineering department, and public indignation is running high. The loss of millions, due to forced industrial inactivity, is lightly considered in comparison with the exposure to fire, cold and pestilence, to which the city found itself a helpless victim.

As a result, it is a subject of open comment that the department responsible for the conditions which culminated in such a disaster should be "cleaned up" forthwith; and that no board of investigation can rightly do otherwise than recommend the immediate removal of certain officials.

Montreal, for some reason or other, has allowed to be associated with its administration a reputation for municipal inertness, deep and of long-standing. Efforts to institute improvements in government have, as a general rule, come to naught. We recollect the city's procrastination in the matter of raising the tracks of the Grand Trunk Railway, the elevation of which would now cost the city many times the amount it would have cost when the question first arose. Again, the case of the Montreal's Tramways Company has dragged on through a number of years without apparent attempt at satisfactory solution. The proposal to purchase the Montreal Water and Power Company has had no unsurmountable obstacles in its way, according to prominent authorities. We do not mention these instances except to authorize a deduction that Montreal does not differ from the average city in the matter of putting off the undertaking of large municipal improvements.

These and similar features of the civic situation in Montreal create an impression that it would be unjust to lay all blame of the failure in the water supply to the fact that the City Engineering Department did not have a duplicate service main to throw into commission when it was so badly needed. In a November issue, *The Canadian Engineer* urged the City of Ottawa to consider, again, the inadvisability of depending entirely upon a single pipe line in connection with its proposed water scheme. The Montreal disaster is an instance in which a duplicate conduit would have saved its citizens its cost of construction times over, apart from the existing dangers to life and property.

But the engineering department of the average city does not entertain the blessed privilege of being immune from such contingencies as the above. It operates in accordance with the dictates of the administration, which is representative of the citizens, and in control of all civic expenditure.

Montreal's water situation has been a problem for fully half a century. It has been undergoing solution. The question is: has the progress been hampered by municipal inertness? The board of investigation will necessarily look beyond the past few weeks in its endeavor to provide the citizens of Montreal with an adequate reply to their query—What is the matter?

SPECIALIZATION AND REMUNERATION.

In addressing the Manchester section of the Institution of Electrical Engineers of Great Britain, Prof. E. W. Marchant recently drew attention to the fields of employment open to the electrical engineer. He dwelt to some length upon his opportunities and the financial prospects which they afforded him. He gave it as his opinion that the great majority of engineers engaged in the electrical industry are much underpaid, with the result that many men who have undoubted ability are leaving the profession, to its great detriment.

The Financial News (London), in commenting upon the remarks of Prof. Marchant, hazards the opinion that his statement might apply with equal appropriateness to men of the civil, mining, mechanical, or other branches of engineering.

"In engineering," it states, "as in everything else, there are plenty of opportunities for men to come to the fore. The trouble is that there are so few, comparatively speaking, who possess any initiative; so few who have the ability to see an opening and avail themselves of it at once, before it is closed forever. There is a certain allurement in setting up for oneself as a consulting engineer, or taking up one or more promising agencies. These are, however, stereotyped—the sort of thing that every engineer thinks about at some time of his life. But years of leanness have to be gone through before success comes to the consulting engineer, and even the most promising of agencies require a good deal of hard work before they bring in adequate remuneration. It must be in other and less hackneyed directions that the engineer must look who wishes to widen his scope. Yesterday was for the general engineer; to-day is a day of transition; but there is no possible doubt that to-morrow will be the day of the specialist, and unless an engineer specializes he will remain one of the rank and file, and never be able to get out of his field into one which will offer better prospects."

The specialization that is spoken of is everywhere regarded as commendable within certain limits, as the range of engineering work has become so extended that it is now necessary to specialize in practice. Still, it has an objection in that, rather than bringing about much "widening of scope," the engineer's mind is largely closed against other specialties. There are men of talent who have devoted their labors to the design, for example, of an electrical device, or to the stress diagrams for a truss bridge, until they seem impressed with the idea that their special work is the sum and substance of engineering. There is a tendency here for the young engineer to overlook the opportunities. He lacks, not the ability to see an opportunity, but contact with the opportunity itself. He possesses a remote idea that some day he will be chief engineer or head of a consulting engineering firm, that great works will be done under his direction, that he will plan immense structures and solve gigantic problems. But, as to how these attainments may best be reached, his mind does not go much farther than to think that they will come to him when he is older. This is often the result of narrowness of vision, produced by over-specialization.

It devolves, therefore, that with "specialization for the engineer," one must associate the danger of over-specialization for the young engineer. To it is to be added an admonition to keep well before his mind those things which he hopes to attain, and to work towards them. The specialization necessary, and the remuneration, too, will each strike new levels as he advances.

EDITORIAL COMMENT.

The Canadian Northern Railway has taken a decidedly commendable and progressive step in organizing a special department to devote its energies to the prevention of fire along the company's lines. This new department will have charge of right-of-way clearance, fire patrols through timbered country, and the construction of fire guards through the prairie sections. The prosecution of protective work along these lines is following out the mandate of the Railway Act and of the Dominion Board of Railway Commissioners.

MONTREAL'S WATER SUPPLY SYSTEM AND ITS RECENT FAILURE

HISTORICAL OUTLINE OF THE DEVELOPMENT OF THE $7,000,000 WATER SCHEME—ITS PRESENT SITUATION—THE RECENT BREAK, ITS SERIOUSNESS AND ITS REPAIR

THE City of Montreal has experienced one of the most serious occurrences that could befall any city with respect to the carrying on of business and the safety of its citizens from fire and disease. On December 25th, the reinforced concrete conduit, which provides the water supply for the city, failed by bursting at a place on the line where adjacent engineering work had excavated to the extent of five feet, or so, below the invert level of the pipe and a minimum distance of 17 feet to one side of it. Several opinions have been advanced as to the cause of the break, but it is generally conceded that it has been the withdrawal of that portion of the support, as mentioned. A full inquiry, to be proceeded with immediately, will no doubt determine whether or not this is correct.

A brief description of the construction of the conduit, together with the circumstances connected with it, may be of particular interest at this time. Originally, an aqueduct built by Mr. T. C. Keefer, of Ottawa, provided the water supply for the city. It was an excavation with a depth of eight feet, a main width of thirty feet, and a fall of approximately five inches per mile. This aqueduct conducted the water from a point in the St. Lawrence River about one and a half miles above the Lachine Rapids and distant approximately nine miles from the centre of the city. This point is thirty-eight feet above the level of the water in Montreal harbor.

In 1877, improvements were undertaken, but they were discontinued owing to a change of plan after about 4,000 feet of the entrance end had been widened to 140 feet, and to a depth of 14 feet. A general profile of the aqueduct before enlarging, together with the proposed enlargement, is shown in Fig 1. Since that time, several schemes have been advanced for a greater and better supply. That suggested by Mr. George Janin early in 1904 included a proposed concrete conduit with a daily capacity of 50,000,000 gallons. The object was to prevent contamination, to which the water supply had for many years been subjected. It may be stated that the danger from pollution hailed from two sources. The Ottawa River brought an impure supply into the St. Lawrence above Lake St. Louis at the western end of the Island of Montreal; and there existed a further liability of contamination of water en route through the open aqueduct. Mr. Janin's recommendation provided for the extension of the intake out into the river some 1,400 feet to clear the Ottawa water which kept well to the northerly shore at that point; and also for immunity from infection after leaving the river, by an enclosed supply line. Another feature of his scheme was that, as this conduit would supply water for drinking purposes, the aqueduct would be used as a canal for power and industrial purposes. When this supply line was established the aqueduct would be emptied and extended in width and depth to make it conform in cross-section with the enlargement begun in 1877.

The Construction of the Conduit.—The recommendations of Mr. Janin, then chief engineer and superintendent of the Montreal waterworks, were approved by a board of engineers acting for the municipal council, and the contract was let to Mr. Patrick McGovern, of Boston, on September 6th, 1907, for the sum of $785,000, the chief engineer's estimate prepared in 1905 being $660,000.

Work was commenced on the conduit in October, 1907, and the job was to have been finished before the end of 1908. Owing to infiltrations from the adjacent aqueduct, however, serious delays were experienced on several occasions, and the conduit was not fully completed within the specified time.

The conduit, the general direction of which is shown in Fig. 2, lies in earth of widely varying composition, from stratified limestone rock to clay which is hard when dry but very unstable when wet. The depth of cutting also varies from 10 to 35 feet. A section of the pipe is shown in Fig. 3. It is of horseshoe shape. The radius of the invert is 13 feet, with a thickness of 8 inches. The inner face of the sides and arch constitute a segment of a circle of 4½ feet radius. The thickness of the crown and lower portion of the sides is 8 inches, while on the horizontal diameter, that of the sides is 12 inches. This section gives a clear inside height of 7 feet 3½ inches, and a width of 9 feet. The walls are of concrete reinforced with No. 7 and No. 12 B. W. G. mesh, the larger strands being 4 inches and the smaller 12 inches apart. This reinforcing was used around the whole perimeter, where soft soil was encountered. Where the foundation was firm the steel went to about 1 foot below the springing line. Specifications called for a 1:2:5 mix of concrete throughout. For the invert and lower side the broken stone ranged up to 1½ inches in size and for the crown and upper part to ¾ inch. In no case was the reinforcing to come within 3 inches of the inner walls.

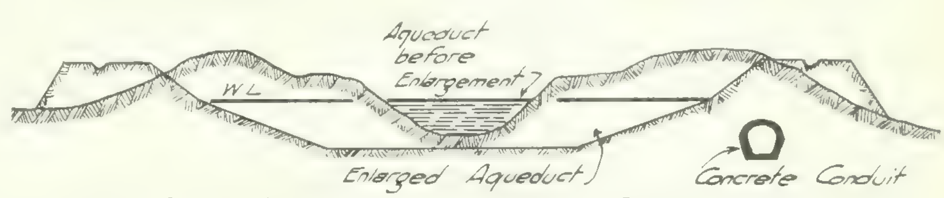

Fig. 1.—Section Showing Relative Position of Conduit and Aqueduct.

The conduit has a grade of 1 in 5,000. Under normal flow the water has a hydraulic gradient of 5 to 10 feet above the top of the pipe.

Other Improvements.—The construction of the concrete conduit was a part of the general scheme of development. A pier about 1,000 feet long had been built at the mouth of the aqueduct to reduce the current in the river. Sluice gates and movable gates in dams, of which

there were two, regulated the level of the water. In 1910, Le Moyne, Fils and L. A. Dery were awarded the contract for the intake, the price being $124,000. The widening of the aqueduct was also proceeded with, and the work was scarcely completed when it was decided to enlarge again with a view to supplying more water for power purposes. Along the enlarged aqueduct there were to be long stretches of boulevarding.

The filters that are being built are also a part of the scheme. Their general design, including the excavation and the construction of the pre-filters and final filters, together with a filtered water reservoir, have been described in previous issues of *The Canadian Engineer*. It will be remembered that in October, 1912, contracts, which had been awarded to the F. H. McGuigan Construction Company in 1911, were transferred to Mr. Norman McLeod. Owing to lack of protection during the winter of 1912, these filtration works suffered considerable damage from the action of frost on the partially completed structures, no provision for protection of the foundation having been made by the contractor. The disturbance by frost resulted in raising and badly cracking the main collectors and floor slabs. The pier bases were raised and tipped. The wall bases were generally raised and some of them severed completely through. Tipping of dividing walls and opening of expansion joints, together with the displacement of the roof groins, were much in evidence. With the warmth of spring, the floor slabs settled, and parts of the structure returned toward their original elevation leaving cracks at expansion joints, and causing considerable spalling.

Failure of the Reinforced Concrete Conduit.—The widening and deepening of the aqueduct has been in progress during the past several years, the present enlarge-

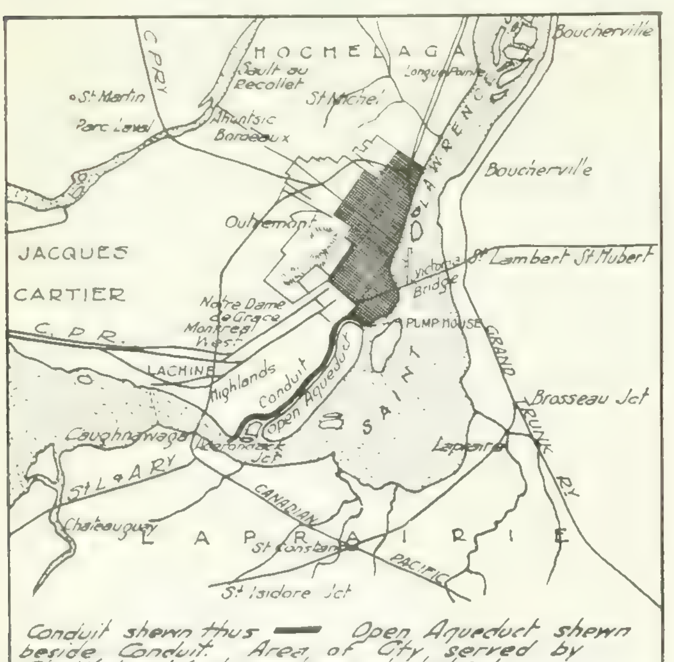

Fig. 2.—General View of Conduit and Aqueduct Location.

ment being carried on by the Cook Construction Company. It constitutes a water-line width of 174 feet and a depth of 18 feet. As may be imagined from Fig. 1, widening to this extent approaches the conduit closely. It appears that about the middle of December, the conduit showed signs of considerable leakage at a point opposite the Verdun Insane Asylum, where the conduit makes a slight bend concave to the Canal, and where the ground consists of loose material. Upon discovery of this the section of the conduit was laid bare and an attempt was made to prevent the leakage by caulking. The canal excavation work was discontinued forthwith. Stone and sand filling were put in behind an outer tier of sheet piling, and on December 23rd the repair work, which had been rushed night and day, was presumed to be efficient and satisfactory.

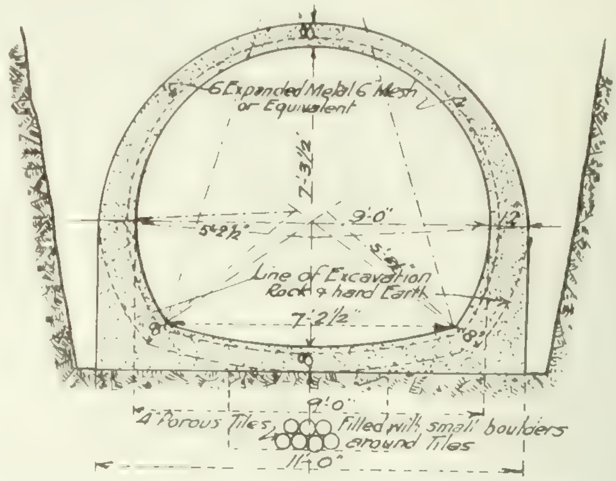

Fig. 3.—Cross-Section of Concrete Conduit.

About 5 p.m. December 25th, a section of the conduit about 60 feet in length broke from the lower portion of the southerly conduit wall at the point mentioned above, and quickly emptied the pipe. Evidently wash and undermining of the pipe had gone on practically unabated. This mishap deprived the City of Montreal, with its population in the neighborhood of 600,000, of its water supply, with the exception of a small domestic supply from the Montreal Water and Power Company, which supplies several suburbs and a few small districts within the city limits; and the distribution of water by carts.

The Work of Repair.—Operations commenced, as soon as laborers could be obtained, to mend the break. It was decided to insert steel pipe into the fissure. While the pipe was being constructed and delivered the break was excavated and the broken portion withdrawn, which operation occupied almost two days. Failing to break the concrete by mudcapping the drag-line bucket which was being used in the aqueduct was utilized as a sledge, and an entire section was removed to the extent of 62 feet. The steel pipe, in lengths of 18 feet, with a ring angle at each end as a bolting flange, was inserted. Seven lengths of it gave a lap of 32 feet at each end. The ends when in position were sealed into the conduit with cement mortar of 1:2:4 mix. The steel pipe with a diameter of 7 feet left a space of one foot on each side, and of 4 inches above and below, between the concrete conduit and the inner shell. Bricks, dropped in bitumen, were inserted as filling, and the concrete was poured directly on the top of the steel tube through holes drilled through the top of the conduit. Steam heating was introduced into the conduit to expedite drying, and coke ovens assisted, at the top and sides of the pipe.

Upon first trial the repair was found to be very inefficient due perhaps to hasty workmanship and insufficient time having been allowed for the concrete to set. The joints, which were equipped with rubber gaskets, were not tightly bolted and the flow of water through them

resumed its undermining effect. This necessitated another emptying of the conduit, and more accurate work being done. The wooden staging supporting the new section was well overhauled. The concrete was more carefully introduced, after all perceptible leaks had been stopped, and was given a full 24 hours in which to set. In the meantime the conduit was very minutely inspected on the inside, throughout its length. As a final precaution large quantities of oakum and bitumen were forced into all interstices which showed any liklihood of weakness.

The head-gates were opened on the evening of January 2nd, and up to the time of writing the restored water supply has suffered no further interruption. Should a repetition of the break occur the old aqueduct will necessarily be put into commission as a means of water supply —a step against which the Board of Health has warned the city because of imminent danger from impurities.

During the eight days' deprivation the civic life of Montreal was in an inextricable state. At three points where the distribution system of the Montreal Water and Power Company approached that of the city, connections were made which provided 15 million gallons a day toward allaying the normal demand for 50 million gallons. Otherwise the circumstance would undoubtedly have been disastrous. Sanitary conditions were becoming alarming; residence heating was severely crippled, while several fires, luckily, mastered in time, showed the extreme helplessness of the situation in case they gained any considerable headway.

The paralytic effect upon industrial activities constituted a loss to be measured in millions. Practically all the large industries, of necessity, acted upon the advice of the mayor and closed down, throwing thousands out of employment.

OIL FUEL.*

By Alfred J. Liversedge.

THE philosopher-historian of the future will pay a good deal of attention to Power—Mechanical Energy—as a factor of the life and growth of nations. When, therefore, he reviews the closing years of the nineteenth century and the early decades of the twentieth, he will note a remarkable expansion in the development and utilization of mechanical energy, throughout nearly the whole of the inhabited globe. He will find this phenomenon manifested particularly in two directions, neither new—one, indeed, old almost as recorded history—but both of which have remained relatively dormant in the past—that is to say, water-power on the one hand, oil-power on the other. It is possible that he will date the rise of an oil age from somewhere about this period. He will surely remark that in the history of organized industry there had not been known hitherto an expansion more rapid in its pace, more remarkable in its character or farther reaching in its effects, than the growth in the use of oil fuel which this period exhibited.

The subject of oil fuel is a very large one, and it would be impossible to do justice to it as a whole within the limits that could be assigned to it here. Fortunately, it divides itself conveniently into several phases, according to the character of the appliances employed to develop the latent energy of the oil. There are three of these general divisions: oil as used for the direct production of light; oil as used in explosion or internal combustion motors for the direct development of mechanical energy; and oil as used in furnaces for the generation of steam, or for metallurgical operations. It is the last of these three phases with which we are here particularly concerned; the others may well be left for consideration on some future occasion, since their importance in industry also deserves our careful attention.

One is so accustomed to associate the idea of fuel with visible combustion in some form of furnace or fireplace that it is, perhaps, desirable to emphasize, in passing, the fact that, whether burned merely for the direct production of light, or consumed without visible flame in the cylinder of an explosion motor, oil is all the time being consumed as a fuel, just as truly as when it is burned in the furnace of a steam boiler. Elementary as this circumstance unquestionably is, it would appear to be often overlooked by those who advocate the substitution of oil for coal. A due recognition of this elementary fact will reveal how wide and varied may be the demand for oil fuel and how many different conditions may require to be taken into account in considering its possibilities in any particular connection.

The whole question has an interest of the first importance; indeed, it may be of a vital character for England. The foundations of the manufacturing greatness of the United Kingdom were laid on the banks of the little streams of Lancashire and Yorkshire, the Midlands, the West of England, the South of Scotland and the North-East corner of Ireland. Those insignificant streams furnished the mechanical energy needed in early days. The superstructure, represented by our position to-day as a manufacturing and commercial nation, has been built with pit coal. In other words, the sources of the mechanical energy by which our eminence in manufactures and in commerce has been won have hitherto been within our own borders and under our own control. The raw material for our greatest manufacturing industry comes entirely from overseas; much the greater part of our wool and a large proportion of our iron come also from abroad; and now it is suggested that we must look outside our borders for the raw material for our power. It is a serious proposition; a proposition which must, certainly, one day be faced, in view of the known limits to our stores of coal; and it is just as well to look at it now while the circumstances permit a calm and leisurelv survey.

Again, it must be remembered that power as a factor of the cost of manufactures is not diminishing in value, it is rather appreciating, and if oil can be substituted on the large scale for coal with the economy which may be attained under certain circumstances, it seems inevitable that the manufacturing centres of the world must gravitate to oil regions, provided only that such regious, of a sufficiently permanent character, are to be found. There, however, lies the crux of the whole position, and the first question calls for consideration.

The use of oil for steam raising is not new. Compared with its employment in explosion motors, its use in association with steam boilers is much the older proposition. Nearly fifty years ago petroleum was tried for some time on a railway locomotive in France, on the line from Paris to Epernay, with results quite encouraging from a

*Abstracted from his article in No. 1, Vol. 1, of the International Review, Dec., 1913.

technical point of view. The speed attained was nearly thirty miles an hour; the oil consumption something under 12 lbs. a mile. About the same time the United States government appointed a commission, of which the chief engineer of the navy was a member, to report as to the feasibility of substituting petroleum for anthracite on ships. The report was favorable, again from a technical point of view. The commissioners found that in regard to evaporation, petroleum had more than twice the efficiency of anthracite, weight for weight, while steam could be raised in one-third the time needed for coal. They, therefore, recommended the government to make a trial on a large scale on one of the ships of the navy, which was done. There were oil enthusiasts then as now, the claim being made that the net saving which the use of petroleum could effect on such a vessel as the then great Cunarder, the "Persia," would amount to $10,000 a trip.

The report of the United States commission was severely criticized on this side, but excited our own naval authorities sufficiently to lead them to make experiments and investigations as to the possibilities of the new fuel—at the time crude petroleum merely was in question. The whole proposition, however, collapsed on the publication of the results of the trials in the States, the conclusions arrived at being that the evaporative efficiency of petroleum as compared with anthracite was only 1.38 to 1, and thus fell far short of the theoretical anticipations, while, generally, "convenience, comfort, health, and safety, were against the use of petroleum in steam vessels, the only advantage proved being a, not very important, reduction in bulk and weight of fuel carried."

The world, of course, has moved since that time; what is more, the cost of oil has gone down with an enormously increased production, while the price of coal has gone up. Even so, until recently it was almost solely in connection with railway locomotives that the use of oil fuel for steam raising had been developed on any large scale. Naturally, the convenience of a liquid fuel which could be supplied and carried as easily as the water needed has appealed powerfully to railway engineers, and nearly every line of any importance has made experiments, more or less, with oil fuels.

In this country, (England) it may be said, the Great Eastern has, perhaps done more in this direction than any other of our railways. In the early stages of this development it was largely a question of utilizing the waste residues of the oil fields because they were waste, and thus relatively cheap fuel. Some interesting problems have in this way presented themselves. Very large quantities of waste residues of the Baku field, converted into a kind of briquette by a process analogous to the formation of a resin soap, have been used on the Russian railways, while the Roumanian railways use similar residues from the Roumanian oil fields combined with their lignite, soft, brown coal. It is obvious that in such cases it is the waste character of the residues which is the determining factor in their utilization as fuel, while it is also clear that this very character must limit the use to relatively local regions.

Needless to say that on the oil fields themselves these residues are utilized as far as possible for heating purposes. Such residues are so used in the works of the Scotch shale oil industry.

It is quite natural to find that in the United States the use of oil fuel on locomotives has been more fully developed—and, perhaps, on more scientific lines—than in any other quarter. The Southern Pacific alone, on its lines in Oregon, Nevada, Utah, California, Louisiana, and Texas, and on the steamship lines which it controls, uses over 25,000 barrels, about 3,500 tons, of fuel oil a day, or nearly 9,000,000 barrels a year. The company has now over 800 locomotives burning oil fuel. Tests made by the engineers of this company have shown that where the mileage per ton of coal has been 5.7, the mileage per barrel of oil has been 1.63, equivalent to 11.4 per ton of oil. The total consumption of oil fuel by the locomotives of the United States, which in 1910 was nearly 24,000,000 barrels, or 3,400,000 tons, is now, probably, at the rate of 28,000,000 barrels, or 4,000,000 tons a year, which, if the tests just mentioned may be taken as a fair guide, is equivalent to 8,000,000 tons of coal. The railways of the States also use large quantities of oil fuel at their depots in the furnaces of stationary boilers. The railways of Mexico and of Austria-Hungary are also now largely operated by oil fuel.

In Canada the Canadian Pacific are using oil on their main line from Kamloops to Field, British Columbia, while the Grand Trunk are also using some proportion. At present these companies have to obtain their oil from the Californian fields, but it is apparently expected, or at least hoped, that future discoveries in Alberta and British Columbia may place the companies in a better position, in due time, in regard to this class of fuel.

It has always been on board ship where oil fuel has been expected to display most fully its advantages over coal. Certainly there is nothing like marine experience to test the merits and develop the capabilities of a fuel proposition, and there can be no question that very great improvements have been made during recent years in the construction of the apparatus employed to burn oil fuel in the furnaces of steam boilers. All the appliances used for this purpose operate by spraying or pulverising the oil with the object of "atomizing" it to the fullest possible extent and thus securing perfect combustion. In a recent French technical journal twenty-three different systems of such oil burners were illustrated. The systems mostly employed may be divided into three classes, as follows:—

1. Spraying by steam jet.
2. Spraying by compressed air.
3. Spraying solely by mechanical pressure on the oil.

The first is the cheapest arrangement to install, but apart from other objections which may be raised to it, so far as ships are concerned, it is practically put out of court by the fact that it necessitates an extra supply of fresh water, a serious consideration where all the fresh water must be distilled. Air-spraying has attained a certain measure of success, but it is the third, or pressure system, which is now being most generally adopted. The British Admiralty use the pressure system exclusively. Very successful apparatus embodying the principle of mechanical pressure are represented by the Babcock and Wilcox system, which has been fitted to over 300 boilers, equivalent to about 500,000 horse-power; the Wallsend-Howden system, made by James Howden & Co., of Glasgow; and the system supplied by Messrs. Kermodes, of Liverpool, who were the pioneers of this method of oil burning. There is no reason to question the substantial accuracy of the evaporative results said to have been obtained by these systems of oil burning for the raising of steam.

The oil fuel used for steam raising on board ship may vary considerably. It may be shale oil or crude petroleum, or any fraction or combination of fractions of

crude petroleum, left after the spirits and (generally) the illuminating oils have been removed, except that it must have a certain limpidity to permit it to flow freely, when slightly heated, through the pipes of the oil burners. The latest specification of the British Admiralty does not permit a lower flash point than 175° F.-Abel close test, or more than 3 per cent. of sulphur or 0.5 per cent. of water, but within the broad limits thus allowed the oil may be anything. As commonly sold as fuel oil, the calorific value may range between 17,000 and 20,000 B.t.u. The best Welsh steam coal will have a calorific value of from 13,500 to 14,500 B.t.u., hence the theoretical relative heating values of oil fuel to the best coal may be taken as 18,500 to 14,000, or the oil has not quite 33 per cent. more value than the coal. A much higher relative efficiency is usually claimed, and must be admitted where average bituminous coal is made the basis of comparison.

Some exhaustive tests made by the U.S.A. naval authorities gave an average relative efficiency expressed in lbs. of water, evaporated from and at 212° F., of 14.45 per lb. of oil consumed to 9.31 per lb. of anthracite coal, thus giving the oil an advantage of over 55 per cent.; but it would certainly appear that a better result should have been obtained from the coal, as it no doubt would be in the best modern steam boilers burning the best coal. As a matter of fact, another series of tests by the same authorities, using hand-picked Pocahontas coal, having a calorific value, dry, of 15,200 B.t.u., gave the relative values of 14.2 for the oil and 10.9 for the coal, the advantage of the oil being thus a fraction under 33 per cent. Still it may be taken that oil fuel has an advantage over good coal of from 33 to 55 per cent. in heating value. It is, of course, this undoubted higher value, *combined with the other advantages* of liquid fuel, which is leading to the adoption of this fuel for ships, and appears likely to result in its use to the exclusion of coal, by all the war navies of the world.

A very competent authority has recently stated that, "The time is fast approaching when oil will be exclusively adopted for all ships, notwithstanding possible higher cost, estimated at 33 per cent., when allowance is made for higher evaporative efficiency." So far, however, the actual tonnage of shipping driven by oil fuel is a very small proportion of the shipping of the world. Probably the total number of merchant vessels now fitted for burning oil fuel does not exceed 250, representing, perhaps, 700,000 tons gross, and very few of these burn oil fuel only. These are exclusive of oil-tank steamers, which now constitute a fleet of something over a million gross tons. In the Pacific, naturally, the conversion into oil burning is proceeding rapidly for the same reason that the United States railways and the railways of Mexico and of Austria-Hungary have so largely adopted oil—the fuel is at hand.

Nor is the proportion of the fighting vessels of the world burning oil fuel as yet very large. Most modern torpedo-boats and destroyers burn only oil, but of the battleships and cruisers none burn oil exclusively. The newer ships are fitted to burn either coal or oil, but coal still retains an enormous preponderance, and must for some time keep it, as the fuel of the fighting ships of the first class. Hence the interest which has been aroused by the announcement of the U.S.A. naval authorities that their new super-Dreadnoughts shall burn oil only, and of our own First Lord that the British Admiralty, in certain of our newest vessels, will follow the American example. At the moment it would appear that the German navy is, perhaps, more completely fitted for oil burning than any other navy of the world.

The situation on land in regard to oil fuel is a very interesting one. Professor Vivian B. Lewes, in the admirable little work on "Oil Fuel," recently issued as one of the "Nation's Library" series, remarks, "At the present time the internal combustion motor plays not only the most important part in power reduction, but also in fuel economy." The statement cannot, of course, mean that gas and oil engines now develop a greater amount of power than the steam engine, but undoubtedly the time is coming when they will do that. At the moment, however, while oil is, to a certain limited extent, through the medium of the oil engine, displacing coal as a source of mechanical energy, it is not displacing coal to any appreciable degree as a fuel for steam boilers in the great manufacturing centres of the world, and that for obvious reasons. The present price of oil fuel in this country, for example, is $17.50 a ton in bulk ex wharf; it was recently more, and may be so again at any time. Thus, granting the highest value, from a calorific point of view, claimed for oil fuel, it is still more than twice as costly as the best steam coal, and up to three-and-a-half times as expensive as other good coal, according to locality. We are thus brought back to the crux of the whole question of oil fuel. What are the prospects or probabilities in regard to the supplies? It is impossible to deal fully here with this vital point, but one or two general considerations may be briefly set out.

Our most eminent authority on mineral oil, Sir Boverton Redwood, opens one of the sections of his great work on "Petroleum" as follows: "In the solid, liquid or gaseous forms bitumen is one of the most widely diffused of substances. It is found in greater or less quantity in almost every part of the globe, while its geological limits include the whole range of strata, from the Laurentian rocks to the most recent members of the Quaternary period." Almost exactly the same thing may be said of gold; but, meanwhile, the actual production of mineral oil, notwithstanding its wide dissemination through the rocks of the earth, does not keep pace with the world's needs. The countries of the world now producing a million tons or more of petroleum a year are the United States, Russia, Mexico, the Dutch East Indies, Roumania, and Galicia. The oil of these countries accounts for 97% of the world's output at the present time.

Of these countries the Russian and Galician productions appear to be actually declining; the increase in the output of the United States in 1912, as compared with 1911, was trifling—if, indeed, there was not an actual decline. The productions of the Dutch East Indies and of Roumania are slightly gaining, but the only one of these great oil regions which shows any important expansion is Mexico. What appears to be happening in most of these regions is well illustrated by the case of the United States, and, after all, the States still provide practically 60 per cent. of the world's output. The production of crude petroleum in the States for the three years, 1904-6, was 50,400,000 tons. The output for the following three years, 1907-9, was 70,370,000 tons, an increase of 20,000,000, or 39 per cent. The yield for the three years, 1910-12, amounted to 87,000,000 tons, representing a gain on the receding triennial period of 16,600,000 tons, equivalent to 23 per cent. Thus the rate of increase in the production of the States is rapidly falling off. It

remains to be seen what will be the next phase, but there can be little doubt as to what it must prove to be.

It must be remembered that the production of mineral oil in the United States is no longer confined to a small area—as is still the case in Russia, for example. Every State in the Union has been exploited for oil, and at the moment seventeen States contribute supplies. It would appear, therefore, that the United States cannot hold any more new oil regions, and that if the output is to grow, or even to maintain its present dimensions, it can only be by more perfectly exploiting the existing fields.

In the British Dominions there is only one region which yields any appreciable amount of mineral oil—Burmah; and while the production of Burmah, with some other regions of British India, shows a gratifying expansion, the total does not yet amount to a million tons a year. The production of Canada is trifling and is not increasing, while Trinidad, of which so much has been expected, is still in the "hopeful" stage.

Nor can it be too often or too insistently impressed upon everyone interested in the question of oil fuel as a substitute for coal for steam-raising on land or sea that the proportion of the petroleum of the world available for use in this connection is very small even now, while the rapid development of the spirit-motor on the one hand, and of the oil-engine on the other, is certain to make that proportion much smaller in the immediate future. Moreover, while much may be expected in due time from modified methods of treating coal, and something from shale, at the moment petroleum represents practically the only source of oil fuel.

It is obvious, therefore, that a policy of the most careful circumspection in regard to the adoption of oil fuel, whether in the Navy or in the mercantile marine, or for use on land, can be the only safe policy for this country to pursue. The authorities of the U.S.A. navy are under no misapprehensions in regard to the chances of oil fuel, and one cannot better conclude the present writing than by setting out the following extracts from a recent letter of Mr. Secretary Lane to the Secretary of the Navy. Mr. Lane remarks: "Crude oil will be available, particularly in Californian fields, for at least a generation to come. . . . . Twenty years hence the price of fuel oil, which then, as now, will be produced chiefly in California, will be much higher than at present, and the production will probably have seriously declined. . . . No relief can be expected in the price of oil fuel at Atlantic ports for commercial uses. Relief for the navy can probably be secured only by the development of its reserves, where it should be possible to produce oil at approximately the present price of 50 cents or less per barrel plus the cost of transportation."

The safety of St. Paul's Cathedral, London, England, which has caused a great architectural controversy for several years, continues to exercise the minds of engineers. It has produced the suggestion that the foundations of the cathedral should be immersed in a moist earth tank. It is proposed to utilize the blue London clay subsoil as a floor on which to build a reinforced concrete wall below the street level of the cathedral and then water the enclosed earth by vertical perforated pipes. It is argued that the recent alarming subsidences are not due to traffic vibrations, but that the moisture has been drawn off the foundations, leaving the foundations parched and unstable and tending to spread.

CONTRACTS AND SPECIFICATIONS FROM THE STANDPOINT OF THE CONTRACTOR.*

By C. A. Crane,

Secretary of The General Contractors' Association.

A CONTRACT, according to the legal definition, is an agreement, for a consideration, to do or not to do a certain thing. Construction contracts usually consist of four elements, the proposal, the plans, the specifications and the contract proper. As you all know, the proposal contains a brief description of the work contemplated, the preliminary quantities and instructions for bidders as to how, when and where bids will be received, the amount of security required, etc. The plans indicate the location and general design of the work; the specifications describe the method of construction and the materials; and the contract itself is the motive power that carries the work to completion. No matter how theoretically perfect a set of specifications you may devise, their successful attainment depends largely upon the form of contract.

In one of the Paris cemeteries there is a fine equestrian statue of a French military hero. The horse is shown rearing aloft at an angle which excites admiration for the nicety in which the balance has been calculated, with the rider gallantly pointing his saber in one hand while with the other he grasps the reins in the tug which has apparently caused his horse to rear. I say apparently, because the sculptor omitted the reins—and it is related that when he discovered this omission his chagrin and mortification drove him to suicide.

Many a piece of work, otherwise faultlessly prepared, has failed because the reins were lacking—the contract form was defective.

We are frequently told that contract forms and clauses are matters for a lawyer to look after—that the engineer is concerned solely with the proper fulfilment of the specifications. It is just because of that view, that so many contracts are a failure. The contract, the plans and the specifications are inter-dependent, and their combined strength is not stronger than its weakest part. The essence and terms of the contract are as much a part of the engineer's province as the plans and specifications. It is the lawyer's province to put into proper legal form the ideas which the engineer desires incorporated. You wouldn's consult a lawyer to draw up your will, and leave the matter of bequests to his discretion. You need him to attend to the legal phraseology and nothing else. And yet too many of our contracts—especially government and municipal contracts—are left entirely to be drafted by the legal departments. The result has been that the engineer is endowed with powers which he never would have thought of himself, and the possession of which sometimes proves embarrassing.

Now, possession of power doesn't necessarily imply misuse of power. History teaches us that there have been many absolute monarchys that have dispensed wise and beneficial government. On the other hand, we've read of some which were quite the reverse. It's the use of power that demonstrates the fitness to possess it—and sometimes it's very costly to determine that fitness.

The broad-gauge engineer knows how to wield this power. But the chief engineer cannot be always on the work—in the field—and his lieutenant, the engineer in

* Paper read before the Society of Municipal Engineers of Philadelphia, Dec. 9, 1913.

immediate charge of the work, is clothed with all the powers of his superior in his absence, and the success of an undertaking often depends upon his judgment and the ability to make instant decisions.

Here are some clauses in Philadelphia contracts which are typical of this power:

"**Changes; Separate Contract.**—Should the Director of the City of Philadelphia change the design or specifications, or both, or any part of the work during its progress, the Contractor shall conform to such change, and the value of the changes, as made, shall be estimated by the Chief Engineer, approved by the Directors, and accepted by the Contractor as final, and no consequential loss of profit on work not executed shall be estimated to the Contractor. The Contractor shall apply in writing for an estimate of the value of the change at the time the change is ordered, and before the next succeeding estimate and payment. Any change to be made at an increased cost of the work shall, at the option of the Director, be executed under separate contract therefor; the work under a prior contract shall be suspended, if necessary, until said changes are completed. The Contractor shall give every facility for making these changes and will not be allowed compensation for delay, except by an extension of the time for the completion of the contract.

"**Construction of Specification.**—To avoid disputes and litigation it must be expressly understood by the bidder that the Chief of the Bureau of Water shall construe this specification, and explain any obscurity herein, and shall have the right to correct any errors or omissions, and shall decide as to its purpose and intent, and his decision upon any doubtful or disputed condition, when approved by the Director of the Department of Public Works shall be final and conclusive and binding upon the City of Philadelphia and the Contractor.

"**Extra Work.**—Whenever, in the opinion of the Director of the Department of Public Works, it shall become necessary to use materials or perform labor which is neither contemplated in the plans of the work, nor implied in the specifications referring to said plans, the Contractor hereby agrees to furnish such materials and perform such labor as extra work, and agrees to accept in full payment therefor a price which shall be fixed by the Director of the Department of Public Works."

What a chance to make the contractor who wasn't in right wish he had never got in at all!

These clauses are clubs, nothing less, in improper hands. If there be any truth in the legal definition of a contract implying a meeting of the minds, there can be no justification for a clause which contemplates the total disregard of one of the minds when any change from the original intention becomes necessary or advisable.

Now, this has been met with the argument that the contractor in signing such a contract, agreed to those provisions, and that the meeting of the minds, for all legal purposes was evidenced by the signatures of the two contracting parties. This is of course true and it is also true that if the advice of counsel were sought every time a contractor intended bidding, he would undoubtedly be told either that he was a fool to sign such a document, or that its provisions could be broken in a court of law.

The success of a contract lies in its manner of execution—not in its wealth of legal protection for the contractee.

So long as the bidding on contracts is unrestricted and the law provides that the award shall be to the lowest bidder, the contract must of necessity be so drawn as to protect the contractee from dishonest practices, not only the dishonesty of contractors but of public officials as well. Contractors can hardly object to this condition nor deny its necessity, but what they do object to is that many clauses which are inserted in the contract more for protection than literal enforcement are often applied to them regardless of good and substantial performance because some inexperienced young engineer who is in charge of the work insists on strict compliance with the specifications. It is one of the difficulties which confront both the contractor and the fair-minded engineer in charge of the work to decide when a contract is not a contract, and these "club clauses," as they are called, furnish the text of the problem.

A prominent contractor in an address some years ago made the statement that if the engineer demands in full that every and all conditions of the specifications be carried out, the job is a failure financially. He went on to say:—

"Every unnecessary or unfair clause in a specification has its part in limiting competition and in lowering the standard of honesty among contractors. A clause that may be used as a club can be avoided in one or two ways—either by not bidding on work governed by the clause, or by using graft in ensuring that it shall be a dead letter."

This second alternative, however, is not always resorted to to avoid the effect of club clauses. They are put in there, as said before, more as a matter of protection than of information. They are to be treated as the chief engineer of one of our greatest public improvements told one of his assistants: "You must use your judgment in interpreting some portions of this contract; they are only meant for bad contractors." So it's evident he thought there were some bad contractors—but he must also have felt there were some good ones—and was able to differentiate.

In almost every contract the chief engineer is the arbiter of all questions and his decision is final. This clause has been kicked at and sued about and condemned by contractors perhaps as much as any other one thing in contracts. And yet there are thousands of contracts, containing just such a clause, completed with never a murmur. So we must conclude that in the long run the engineer is the proper party to wield this authority and that it has been wielded fairly. It bears testimony that the engineering profession as a whole is conducted on a high plane of honesty and intelligence—not even the learned profession of the bench and bar can point to so few reversals by higher authority. But there are exceptions—you all know of them—and it is those exceptions that cause the trouble and turn the contractors' profits into lawyers' fees.

We come back to the use of this power of absolute determination. How can an engineer who is employed by a party to the contract and is virtually the agent of that party render a fair and impartial decision when a dispute arises relative to the work which he himself designed and of whose requirements he is presumed to know more than anyone else? Simply by bearing in mind that the contractor also is an agent of the same party—not an enemy who must be outwitted.

Now, we have heard the adage, "Knowledge is power"—but oftentimes this power conferred by the contract is vested with an engineer before he has the know-

ledge. Some engineers are too narrow to realize that a specification is a standard, and that an approximation to that standard fulfils the contract. The man who rejects masonry because the joints deviate a fraction from the specifications, or piles because they are a half-inch under size at the butt, doesn't appreciate that he is standing in his own light—he never becomes a big engineer—he never has time to learn engineering—he is too busy inspecting.

It is amusing, sometimes, to note the very radical change of views which an engineer undergoes when he ceases to be the engineer for the contractee and becomes either a contractor himself or an engineer for a contractor. The very policies which he so tenaciously followed become most repugnant to him now that he is forced to toe the same mark himself. In fact, a prominent contractor who is to-day the president of a large contracting firm, stated in a public address that he could speak understandingly and feelingly on the relations between the engineer and the contractor because for the first few years after graduation he was employed as engineer for the owner and that now, when he looked back upon some of the ideas which he felt inspired by a conscious duty to enforce, he felt that he ought to pay a personal visit to certain contractors and try to square himself for the damage he had caused.

The knowledge requisite to use this power comes only through experience—and unfortunately there are some personalities that can never assimilate it in a bi-partisan spirit. Such men have never been able to find out for themselves whether there really was any room at the top or not—and rather doubted it anyway. But most of the mistakes arise through an excess of zeal rather than from any desire to be drastic. Not long ago an instance of this came to my notice. A young engineer not long out of college was in charge of a party on one of the tunnels in New York and he was very much concerned over the method of timbering employed by the contractor in a piece of bad heading. He insisted on some changes but the contractor intimated that the suggestions weren't feasible. The chief engineer happened along and the young engineer complained that his orders were not being obeyed. The chief took him aside quietly and told him that they were very fortunate in having this particular contractor on that piece of work—he had been driving tunnels for over thirty years and knew more about timbering than the chief himself, "and," he remarked, "I guess we better let him do it his own way."

In this case there was no harm done—the matter was so tactfully adjusted by the chief that his subordinate suffered no loss of dignity—and the work was not endangered at a critical point by ill-timed experiments. Had the engineer prevailed, and his method failed, would the contractor have been responsible?

This brings us to a clause which is frequently found in contracts, which holds the contractor responsible for the performance and safety of his work while the method of construction is specified.

The specifications provide how the work shall be done, what materials shall be used, and the contract contains a clause shunting upon the contractor all responsibility for the accuracy and sufficiency of the plans to produce a structure that will insure a desired result. The contractor is required to guarantee the efficiency of the completed work without having a word to say as to its design. This is manifestly wrong. The contract should prescribe only one of two things—either the design or the performance. It should not stipulate both, for if it should occur that the design were insufficient, the contractor should not be held for the failure in performance. Contractors may be pardoned for feeling that the engineer who attempts to shift the responsibility for the work which he himself is paid to assume, upon a contract or is technically dishonest and betrays a lack of faith in his own ability. In such cases the courts will not always uphold the engineer.

An important case involving this very point was decided by the United States Court of Claims within the past year in what is known as the Boston Dry Dock case. The contract provided that the contractors would, at their own risk and expense, furnish and provide temporary structures of every description necessary for the construction of the dry dock, subject to the approval of the engineer in charge. A question arose about the design of a coffer dam and the engineer in charge designed a structure which the contractors protested was insufficient, but upon the insistence of the engineer they built it. It subsequently failed. The court found that the defects which caused the failure were such as an exercise of ordinary care and skill on the part of the government engineer would have foreseen, and awarded the contractors their claim for damages.

It is impossible to over-emphasize the importance of the relation of the engineer who is in direct charge. He is called upon to give immediate decisions on important questions, in the absence of his superiors. He is clothed with all the powers conferred in the contract and these are liable to be over rather than under-exercised by the too zealous and inexperienced engineer. Care in the selection of his deputies, and personal attention to their training by a chief engineer are tremendous factors in securing harmonious relations with the contractors. Constant bickering prevents good work, and the chief engineers who have been most successful are those who have impressed upon their subordinates the realization that tact and diplomacy win more battles than obstinacy.

There has been some agitation within the last year by some engineers and contractors to reform the present contract system by legislation—to enact universal statutes governing contract provisions. Personally, I am not a believer in the power of legislative enactment to effect any such reform. The engineers to-day have all the power at hand to revise, standardize and perfect their contracts that is necessary—statutes merely serve to tie their hands, and no statute can be devised that will fit every case. I believe in giving every latitude to the engineer—he has proved that he is about 90 per cent. fair and the other ten per cent. we continue to wrestle with in the hope of reform.

The attempt to regulate the relations between contractors and public officials and to prescribe by statute for nearly every contingency that may arise in a contract is in my humble judgment a mistake. Laws are no stronger than the men who enforce them, and if it be the fact that laws are necessary to curb our public officials, something is radically wrong with our system of government. You can't legislate honesty into a man—you may render him more cautious, but if he be dishonest he will beat any law you can make. What we need is better men, not more laws, and public office should offer the best men suitable compensation for their services to the public.

If the process of perfecting contract practice, the contractor should be considered. He is the practical factor in the game, and theory must go hand in hand with practice, or the result will be worthless. The contracting business to-day numbers among its members many of the leading engineers of the world, and their experience and advice must not be under-estimated. It wouldn't do for these matters to be discussed just between engineers. Two heads are not always better than one; if they be on the shoulders of two engineers there is apt to ensue a wrangle over technicalities and the subject matter is liable to suffer, but if one head be that of a contractor, expert in his line, and the other an engineer, each equally mindful of his reputation, the result will invariably prove the wisdom of the adage.

Now on the subject of bidding. Bids are usually invited in one of two ways, lump sum for the entire work, or on a unit price basis. There are also the methods of cost plus a percentage and cost plus a fixed sum, but they are not in general vogue. The lump sum method is followed more in building construction, and the owner knows just what the building is going to cost him, provided he doesn't change his mind and the plans too often. The character of the work is such that everything may be provided for and shown on the plans. There are no unforseen contingencies liable to occur that will affect either the plans or the quantities, and the bid is figured directly from the plans and specifications. If anything has been omitted, or any additional work is required, it is a matter of subsequent agreement between the owner and the contractor. Needless to say, these extras are sometimes fairly profitable to the contractor, since the owner is not in as good position to drive a bargain as before the work was awarded.

On engineering works, the unit price system is preferable, because of the impossibility to foretell just what conditions will arise as the construction advances, and with the price fixed on each item, there is less opportunity to claim extras. Not that they are not claimed, but the owner is in a better position to resist the demand than if he were bound down to a lump sum for a specified amount of work. We have already seen how the owner protects himself in the contract by disavowing responsibility for the accuracy of the estimated quantities, and how impregnable his defense is. There are extreme cases, however, where the contractor has won his point, when the original quantities proved to be so far out of the way as to present an entirely different proposition from that contemplated. But with proper investigation beforehand, including soundings and borings, this is inexcusable, and yet bear this in mind—that contractors every day are bidding on quantities prepared by engineers they never heard of—in many cases the job is the first some engineer has had—and he relies on the integrity and intelligence of that engineer and pins his hopes of profit on the accuracy of his survey and his figures. Is there any other profession in whose members so much trust and faith are reposed by utter strangers? If a contractor needs a lawyer he will retain the best he can get; if he needs a doctor he will call in one with an established practice, but he will risk his money on the mere say-so of an engineer he never heard of, who may be bearing the title of engineer merely by courtesy, or because of a correspondence diploma. Isn't it high time that engineers generally paid more attention to the preparation of their work than is so frequently the case?

While we are talking of bids, a few remarks on some peculiarities that they sometimes offer may be apropos. I refer to what is called the unbalanced bid—some call it balanced—but unbalanced seems a better definition. This occurs only under the unit price method of bidding. It is a very common practice for engineers in preparing the schedule of quantities to include items which there is some possibility of needing, in a merely nominal amount. The contractor who is doing work of a similar character in that vicinity believes that those items will not be used, and bids one cent or nothing on them. As it turns out they are not used and he has not lost anything. If they had been used, that would have been another tale. Now the unbalancing consists in placing the cost of an item which the contractor has reason to believe will be diminished, on another item which he is sure will be done, or perhaps increased.

There have been cases where the contractor who bid one cent on timber has been required to put in the full amount, but even should that be the case, he is fully protected by including its cost in another item. Of course, when he bids one cent on timber, he is going to use his best efforts to persuade the engineer that the timber is not necessary and when he bids a high price on an item he is going to be equally as persuasive that the job will be a failure unless a large quantity of that particular item is used. It would seem that the logical way to avoid this situation is to insert in the contract an agreed price for any item which may perhaps be required, but the necessity for which seems doubtful to the engineer in preparing his estimate. In this way every bidder would be on an equal footing and would be competing only on the items which were sure to go in the work.

Now, while there is much to be said on both sides about the subject of unbalanced bids, engineers should not lose sight of the fact that they themselves are directly blamable for any disastrous results. If engineers exercised the proper precautions in preparing their estimates, there would be no reason to fear the unbalanced bid, nor would there be any necessity for devising methods which would prevent them. Avoid unbalanced quantities and the unbalanced bid will disappear except occasionally where the contractor bases his price upon the work which is first to be done in order to get his largest payments at the start to finance the job.

There is very little unbalanced bidding on the contracts for the Catskill Aqueduct or for the subways. The estimates have been carefully prepared and the contractors generally have bid a suitable price on each item—but where a contractor has reason to believe the engineer's quantities are wrong, he should be privileged to use his own judgment in preparing his bid.

Bear in mind that a contractor is most generally a human individual—not nearly so wealthy as the newspapers love to depict him—and that for every crooked contractor there has been some crooked official somewhere in the offing. My experience with contractors, and it has been my privilege to know a great many, has led me to believe that they are as honest a lot as in any other line of business or profession. As an afterdinner speaker in the course of his remarks stated, it is one of the peculiarities of human nature that the indiscretion of one woman makes more noise than the good conduct of a thousand. And this is quite applicable to contractors, too.

MECHANICAL AND ELECTRICAL EQUIPMENT OF HOTEL FORT GARRY, WINNIPEG.

The power plant equipment for the Hotel Fort Garry is a notable instance of the placing of the complete equipment in the hands of one engineering firm instead of purchasing the various individual pieces of machinery and apparatus from various sources. The advantages of placing the entire responsibility on one company are apparent even to the layman. An engineering firm manufacturing equipment which has a reputation for satisfactory operation and economy, should be in a position to provide and install the complete equipment, eliminating the division of responsibility and insuring the purchasers an installation in which the various pieces of machinery and apparatus bear the proper relation to one another and are so proportioned as to give greatest satisfaction.

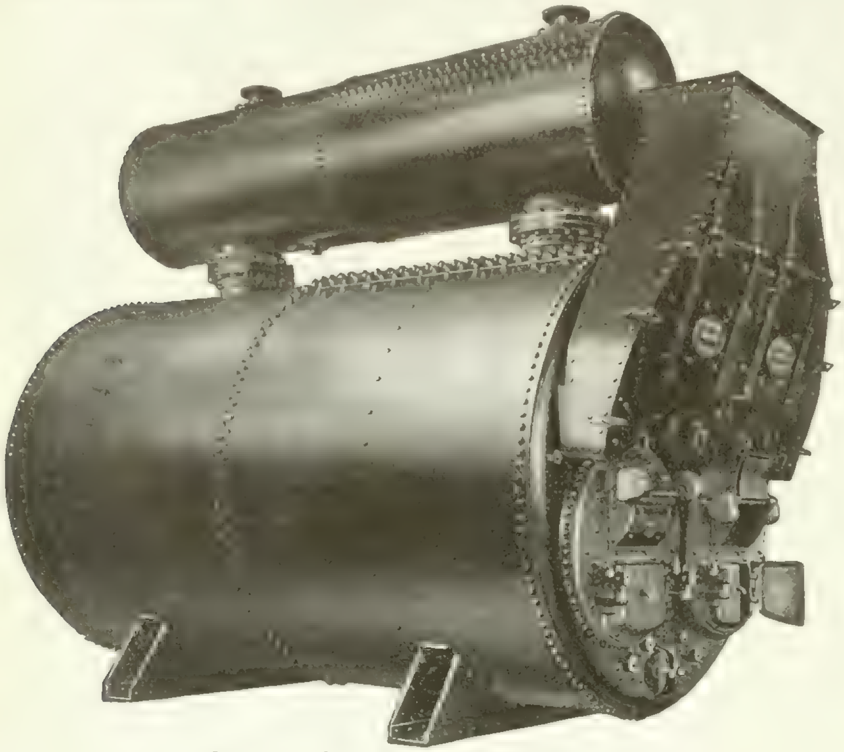

Fig. 1.—One of the Four 300-h.p. Boilers.

The International Engineering Works, Limited, of Amherst, N.S., undertook the complete power plant equipment of this hotel in accordance with the drawings and specifications prepared by Ross and MacFarlane, architects. The broad scope of this installation is shown from the fact that they were to supply not only the Robb boilers, engines, etc., of their own manufacture, but were to fit into the general scheme such other machinery and apparatus as would provide for refrigeration, electric light, water softening, etc., these larger pieces of apparatus of course to be accompanied by their accessories such as feed water heaters, boiler feed pumps, service pumps, switchboards, etc.

The four boilers selected for Hotel Fort Garry are of the Robb Scotch type which are internally fired. These boilers each of 300 horsepower are a modification of the standard Scotch marine boiler, the chief difference being the division of the one large drum into two drums. In this case the steam drum, 18 inches in diameter, is connected by short necks to the large shell 120 inches in diameter containing the two furnaces, combustion chamber and 220 three inch tubes 14 feet long.

These boilers are equipped with corrugated furnaces 40 inches in diameter extending from the front to the combustion chamber. Although internally fired these boilers have very rapid circulation, which is accomplished by means of a circulation plate at the front which compels the water from the drum to pass around the shell and rise between the furnaces and amongst the tubes passing to the rear. The two features which contribute to the high economy of this boiler are rapid ciruclation and internal firing.

Another product of this company that was utilized, was the Macdonald shaking grate. These grates were supplied to all eight furnaces. They are of the shaking type with removable tops which reduce repair expense. The improved locking device insures long life by preventing any possibility of the points becoming burned off.

The three Robb vertical engines are of the compound, high-speed type direct-connected to 200 k.w. generators. The cylinders of these engines are 18 and 26 inches in diameter with a stroke of 10 inches. Their high speed,, 360 r.p.m., makes them ideal for direct connection to generators as well as furnishing a very powerful prime mover occupying a small space. An automatic system of lubrication which provides for pumping the oil by the engine itself to every sliding and revolving surface reduces care to a minimum, and complete enclosure of all moving parts insures perfect cleanliness of the engine room and protects the parts from accidents. These engines are also supplied with oil guards which prevent the oil creeping along the shaft to the generator.

The compound engines are operated at 120 pounds initial pressure and with five pounds back pressure have sufficient capacity to carry 25 per cent. overload on the generators. The automatic shaft governor is so sensitive that the speed does not vary more than 2 per cent.

The generators are compound-wound, manufactured by the Canadian Westinghouse Company, Limited, Hamilton. To fulfil the specifications these generators had to operate continuously without blackening the commutator and carry 25 per cent. overload for two hours with an increase in temperature not more than 55 degrees C. The International Engineering Works, Limited, through sub-contractors, the American Water Softener Company, installed a water softener of 6,000 gallons capacity per hour, with settling tanks 10 feet in diameter and 22 feet high. The water softening apparatus softens the water through chemical solutions so that the scale matter does not exceed five grains per United States gallon.

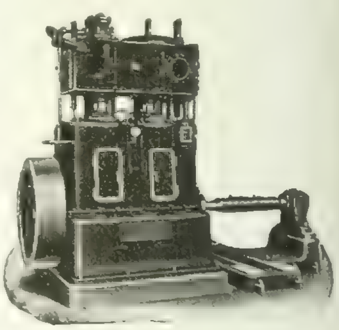

Fig. 2.—Type of Engine Used.

The refrigerating plant of Hotel Fort Garry consists of a 30-ton refrigerating outfit. Two 15-ton double-acting ammonia compressors made by the Linde Canadian Refrigerating Company are driven by two slide valve engines. The installation includes double pipe ammonia condenser with brine cooler, liquid ammonia reservoir, and brine storage tank. On the roof of the hotel there is a 5-ton condenser piped through the building to charcoal filters placed in series and double-pipe cooling coil.

COAST TO COAST.

Victoria, B.C.—Considerable discussion is being given to the advisability of the use of brick or concrete pipe in the north-west sewer construction. The city engineer is preparing a report upon the merits of concrete pipe.

Winnipeg, Man.—Recently, Reeve Bannatyne of Assiniboia, officially turned on the electric current at the St. James power house, setting in lumination 61 arc lights along Portage Avenue, west from the city limits to Headingly.

Woodstock, Ont.—One of the first problems with which the new town council will be called upon to deal, concerns the decision as to the application of the Maine and New Brunswick Power Company to bring its electric power to Woodstock.

Ottawa, Ont.—At Ottawa, 1913 has proven to be a record year in granolithic walk and macadam street construction. About 14 miles of walks and crossings were laid, while about 10 miles per year is the average mileage. Also 5 miles of asphalt pavement were laid.

Ottawa, Ont.—The financial statement for the township of Gloucester for 1913 shows the income to have been $47,-464.53; the expenditures, $46,450.28; and the surplus, $1,-014.25, the greatest the township has yet had. One of the most important works accomplished was the construction of the road from Gloucester to Cumberland at a cost of $1,170.10.

North Burnaby, B.C.—On December 23rd, the new extension of the Hastings Street east railway line to a point near the foot of Capitol Hill, was officially declared open for traffic by Reeve McGregor. Members of the Municipal Council and representatives of the B.C.E.R. Company were present at the formal inauguration; and some of these also took part in the formal proceedings.

Regina, Sask.—It is expected from the indications on the progress of the work of installing machinery and valve connections, that the new water distributing system for the city will be inaugurated and put in operation some time next month. The new pump of a 5,000,000 gallon capacity is expected to arrive early in February, and it is hoped to have all in readiness to mount it on the concrete foundations, and to assemble the parts.

Swift Current, Sask.—The large storage dam across the Swift Current river, which will ensure a supply of water for a population of at least 50,000, was formally opened recently. The dam, which is over 800 feet long and 25 feet high, was constructed by the Ambursen Hydraulic Construction Company, of Montreal, under the supervision of George K. Mackie, town engineer, at a cost of $100,000; and will have a capacity when filled of over one hundred million gallons.

Vancouver, B.C.—Work on the Point Grey partnership pipe has started under the supervision of Mr. J. T. Breckon, the city's new waterworks engineer. Seventy men were put to work on the trench at Chilco and Haro streets in the West End, where the pipe-laying was stopped pending the settlement of the route. This number, however, will likely be increased as soon as the work is properly under way. Waterworks Superintendent Maddison is in direct charge of the construction work.

Edmonton, Alta.—Steel on the Edmonton, Dunvegan and British Columbia Railway construction is reported to have reached mile 131, or where the town of Smith is located. Here, also, a temporary bridge has been constructed across the Athabasca River, which in time will be replaced by a steel structure. Grading has been carried out as far as mile 220, while surveys have been completed to mile 310. The road has advanced sufficiently to permit of announcement by Chief Engineer Smith that a freight service will be put in operation shortly.

Fort William, Ont.—Six hundred miles of double-tracking on the C.P.R. are waiting for steel, and the company has just closed an order for 125,000 tons of steel for this purpose. When that track-laying is completed the company will have on the entire system east and west but 488 miles to be built. The districts where double-tracking is proceeding at the present time are Sudbury to Fort William, Brand to Calgary, and Revelstoke to Vancouver. When this work is completed there will be 1,095 miles of double track between Fort William and Vancouver, and over 200 miles between Sudbury and Fort William.

Orillia, Ont.—The annual report of the water, light and power commission engineer, shows that the average pumpage for the period from May to November, 1913, was 502,090 per diem, or 67 gallons per head of population; and that the heaviest day's pumping was 841,500 gallons, or 112 gallons per head of population. In the electrical department, the report shows the amount of motor power in use to be 1,297 horsepower. Engineer Greenwood makes the comment that the electrical system is now in very satisfactory condition, and it should be possible to improve the record of service during the coming year very materially.

Vancouver, B.C.—It is reported from the office of the general superintendent in Vancouver that work on the "pioneer" bore in connection with the five-mile tunnel for the C.P.R., which is to be driven through Rogers Pass, at the summit of the Selkirk Mountains, is well advanced from the eastern portal; and that nearly 600 feet of the parallel tunnel has been excavated, the present rate of progress being about 5 feet per day. In order to facilitate the driving of the big bore the contractors are adopting a new method of procedure. They are running a small preliminary tunnel from which cross cuts will be made at short intervals so as to enable the workers to attack the larger bore simultaneously at scores of points. This "pioneer" passage will also solve the question of ventilation and provide for a considerable time an exit for removing the excavated material.

Vancouver, B.C.—In connection with the construction of the G.T.P., Mr. Morley Donaldson, vice-president of the company, has announced that at the present rate of progress, the two ends of steel will be connected by May 10; that construction, which is proceeding at the rate of 3 miles a day, 1½ on the western section and the same amount east of Prince George, will be carried on all winter; and that steel will be laid into Prince George by January 10. The Grand Trunk Pacific, during the year, concentrated, for the most part, its efforts on the completion of the main line of the western division, which will connect Winnipeg with Prince Rupert on the Pacific Ocean, and also on the completion of the branch lines in the provinces of Saskatchewan and Alberta, with the result that the 14 separate branch lines under construction in the provinces aggregating a total mileage of approximately 1,000 miles are now about completed. In addition to this, about 300 miles of main track line were laid in British Columbia.

Calgary, Alta.—At the annual meeting of the Industrial Bureau, it was announced in the report of Commissioner Miller that extensive investigations which have been completed by Government engineers, under the direction of Mr. J. B. Challies, superintendent of the water power branch of

the Department of the Interior, [illegible] the power possibilities of the Bow and Elbow Rivers within feasible transmission distance of Calgary, show that on the Bow River alone it is economically feasible [illegible] to regulate the flow as to warrant the development at four power sites of over 40,000 dependable 24-hour horsepower, all within 50 miles of Calgary. The Calgary Power Company has completed an installation at Horse Shoe Falls of a maximum output of 18,000 horsepower, which is mainly transmitted to Calgary; this company will within a few weeks have a second power installation completed at Kananaskis Falls, capable of an additional maximum output of 11,000 horsepower. With these water powers developed there would be 70,000 horsepower available in the Bow River alone.

Toronto, Ont.—Favorable progress is being made on the two Don bridges. The contractors for the concrete foundations of the new duplicate bridge over the east Don, Messrs. Dickenson & Burns, expect to complete the pediments in about two weeks, while the Canadian Bridge Company, of Walkerville, has its construction train and steam hoist upon the ground, and has already unloaded a large number of the girders and the beams for the towers. This bridge is about 1,000 feet in length, its widest span being on the west side and over the C.N.R. It is 80 feet above the C.N.R. and 120 feet above the bed of the river. In addition to the pediments, a retaining wall 8 feet wide, alongside the C.N.R., is required to carry one side of the tower. Over one half of the bridge over the west Don has been completed by the Dominion Bridge Company. This structure is over 800 feet long.

Winnipeg, Man.—The report on civic improvements carried out in Winnipeg 1913, shows a total cost of $1,224,730.60. The total cost of pavement laid by both Engineer of Construction Astley and outside contractors to have been $470,-848. The tender of the engineers of construction for asphalt pavements (No. 1) was $344,000; but the works were completed at a cost of about $11,000 less than that amount. The amount spent on asphalt pavements (No. 2) was $57,969. Small sections of macadam gravel and block pavement also were laid by the engineer of construction; and these as well as the asphalt pavements were laid at costs less than the tender prices. In the case of sewer construction for the year, however, the actual cost, $275,610, exceeded the tender price by about 10 per cent. This, in turn, was more than counteracted by a saving of 13 per cent. on granolithic sidewalks, made possible by the purchase and use of several concrete mixers. The total expenditure for the year on granolithic sidewalks was $116,875.60. The cost of water mains was $174,584, or 18 per cent. above tender price, the extra cost being incurred by the laying of three high pressure mains, and one domestic main during the winter when there was from 6 to 8 feet of frost in the ground. A saving of 3 per cent. and 7 per cent. on tender prices is shown in the construction of concrete pavements and plank walks respectively. The new 18,000,000-gallon reservoir was constructed at the very moderate cost of $307,000, which included the cost of foundations, though not the cost of land. Again, though the cost ($265,-000) of the Osborne Street bridge across the Assiniboine River was mostly paid for in 1912, yet this important improvement was completed last year, the approaches and towers projecting the work well into the summer. Other municipal works on which large sums were spent, were the erection of two hospitals, the building of two new fire stations, extensions to the street railway system, a new police signal alarm service, the improvement of the city light and power plant, the extension of the artesian well system, and some preliminary work in connection with the Shoal Lake water supply. The money expended in the last of these will be refunded to the city by the Winnipeg Water District Board. Of the $750,000 which was allotted to the light and power department, $250,-000 still stands to its credit to be used for the installation of additional turbines at Point du Bois, the contract for which has been let, the work to be completed next spring.

Sarnia, Ont.—The increasing business of the Standard Oil Company is occupying the directors with the devising of plans and means for increasing the present plant of the company to a capacity sufficient to handle all the work that can be ordered. The company has completed the pipe line to the great oil fields of Ohio, and thus has an unlimited supply of crude oil to draw upon at all times in the year. At the present time the company has on its payroll about 1,500 men, many of whom are at the work of rebuilding the refinery and increasing the capacity of all parts of the enormous works. It is reported that during this winter the company will erect over 20 stills, with condensers for the same, and buildings to look after the by-products. Four of these stills are now under erection on the west side of the yard. A start has already been made on a battery of 12 crude stills to be constructed south from the battery now opposite the Pere Marquette Station. A new set of six stills has already been constructed in the rear of the crude stills, and a battery of half a dozen more will be added to these. At the new works, which are about a quarter of a mile from the offices of the company, the work of building the new motor spirit refinery is being rushed. The foundation for a battery of ten stills, each with a capacity of 300 barrels, has been completed, and the work on the foundations for the necessary condensers is in progress. The digging for three large underground tanks has commenced. This work will incur great cost, but is very necessary for the storage of the new spirit, which is used for operating automobiles, as it is very explosive in comparison with the gasoline now in use.

Victoria, B.C.—In connection with the tunnel work on the northwest sewer, two shafts have been sunk at McLoughlin Point at either end of the bluff of rock which interposes between the end of Smith and Robert's streets, and at the junction of Bay Street and Anson Street, with a view to open a tunnel face. A section has been opened in an earth and rock cut a little further south; and although it is deflected from the original point set out for an outfall, to avoid the current washing back sewerage into the harbor, the character of the outfall may be gauged. The intention is to carry the sewerage out to a natural tank which can be contrived by damming up the ends, and covering a basin between the land and an islet of rock at Macaulay Point. From that tank the sewerage will be carried out to sea by a submerged pipe, the exact nature of which has not been determined, but will be dependent upon further tests to be made by the engineers upon the flow of the currents. From the piercing of the two shafts, it has been found that it is particularly hard material through which the tunnel has to be driven. The other large tunnel in Esquimalt municipality is the one at Dunsmuir Street. In this case, as in that of Smith Street, it will be necessary to excavate sufficiently not only for the actual pipe line, but for inspection. The third tunnel of large size will be in Victoria West, the location depending upon the point fixed for the crossing of the Victoria arm with a syphon. Assistant Engineer Payne, after an examination of the character of the district, has recommended to the city engineer that a direct tunnel from the Gorge Road to Dominion Road would be most satisfactory, but the subject is still under advisement. The pumping station to handle the low level sewerage north of the Gorge will be located at Cecilia Road, instead of at the waterside as has been proposed. In this section between Burnside Road and the Gorge waters earth is being excavated.

Vancouver, B.C.—The Burrard Inlet Tunnel and Bridge Company adopted a resolution recently to call for tenders for the bridge to be constructed across the Second Narrows. They took this action in view of the facts that the Provincial Government cannot yet give a definite answer to the company's request for information as to the construction of the proposed Second Narrows bridge, and that the company's charter expires next spring. They deemed it incumbent upon them to have some tangible evidence of their intention to proceed with the proposed construction, so as to strengthen their application for renewal of the charter privileges. The company is capitalized at $3,000,000, of which sum one quarter has been subscribed by the municipalities interested. The Dominion Government has granted a subsidy of $350,000, and the Provincial Government a subsidy of $400,000. Thus more than one-half of the total amount required for the project has been assured. The Provincial Government will be asked to guarantee a bond issue of $750,000, the amount upon which the company is allowed to raise funds under the terms of its charter. The structure will be of steel with wide spans, and will be supported on six piers founded on rock. The draw span will measure 581 feet 6 inches in length from centre to centre, and will revolve on a platform supported by four wrought steel cylinders, braced together and filled with concrete. The fixed spans will be 232 feet long. A clear headway of 45 feet above the level of high-water mark will be provided, and the bridge will cross the Narrows at an angle of 75 degrees to the average direction of the flood and ebb currents, which are very powerful at that point. A channel with an average minimum depth of 35 feet will be dredged to allow the passage of large ships. The bridge will be 64 feet 5½ inches in width. On the west side, a single line of railway tracks will be laid; in the middle of the roadway, which will be 39 feet 5½ inches in width, double street car tracks; on the east side, an eight-foot path for pedestrians. The approaches will be on an easy gradient, one foot in thirty, with a one per cent. grade continuing to the centre. The swing span will be operated by electric motors, and gates, also electrically controlled, will automatically safeguard traffic when the draws are opened. Wrought steel trestles will support the approaches to the bridge, strongly reinforced with longitudinal arms resting on concrete foundations. The superstructure will consist of wrought steel stringers, supporting deck ties of Douglas fir. The roadway will be paved with creosoted wood blocks; and extra substantial spans will carry the approaches for the steam tracks. Exclusive of the approaches the structure is estimated to cost around $2,225,000.

PERSONAL NOTES

R. G. SNEATH has joined the engineering staff of the New Welland Ship Canal at St. Catharines, Ont.

H. D. CLEMENSON has been appointed by Prince Edward County as commissioner to take charge of the county system of road improvement.

WALTER HAZLETT has been appointed mechanical superintendent of the Canadian Steamship Lines, Limited, with headquarters at Montreal.

PHILIP P. SHARPLES, Chief Chemist, Barrett Manufacturing Company, Boston, on December 27th delivered an illustrated lecture on "The Manufacture of Refined Coal Tar" before the graduate students in highway engineering at Columbia University.

W. NORRIS, general manager of the Chatham, Wallaceburg and Lake Erie Railway, has been mentioned for the position of general manager for the London and Port Stanley Railway. Mr. Norris was formerly engineer of the Winnipeg Street Railway.

ARTHUR N. JOHNSON, M. Am. Soc. C.E., State Highway Engineer of Illinois, Springfield, recently delivered an illustrated lecture on "Economics of Highway Engineering in the Middle West" before the graduate students in highway engineering at Columbia University.

SIR DOUGLAS COLIN CAMERON, K.C.M.G., Lieutenant-Governor of Manitoba, who was included in His Majesty's list of New Year's honors, is vice-president of the Manitoba Bridge and Iron Works, of Winnipeg, and has figured prominently in the engineering development of the West.

E. A. JAMES, engineer to the York County Highway Commission, Toronto; A. J. McPHERSON, chairman, Board of Highway Commissioners for Saskatchewan; JOHN STOCKS, Deputy Minister of Public Works, Alberta, and ALEX. McGILLIVRAY, Provincial Highway Commissioner for Manitoba, were chosen by the Automobile Federation of Canada as consulting engineers to advise the Federation respecting the road construction, improvement and materials most suitable to the needs in their respective provinces.

COMING MEETINGS.

MINING AND METALLURGICAL SOCIETY OF AMERICA.—Annual Meeting will be held in New York City, January 13th, 1914. Secretary, W. R. Ingalls, 505 Pearl Street, New York.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

NATIONAL CONFERENCE ON CONCRETE ROAD BUILDING.—Meeting will be held in Chicago, Ill., February 12th to 14th, 1914. Secretary, J. P. Beck, 72 W. Adams Street, Chicago, Ill.

AMERICAN SOCIETY OF ENGINEERING CONTRACTORS.—Annual Convention to be held in New York City, January 16th, 1914. Secretary, J. R. Wemlinger, 13 Park Row, New York City.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Annual meeting will be held in Montreal, Que., January 27-29, 1914. Secretary, Prof. C. H. McLeod, 176 Mansfield Street, Montreal, Que.

AMERICAN SOCIETY OF HEATING AND VENTILATING ENGINEERS.—Annual Meeting to be held in New York, January 21st to 23rd, 1914. Secretary, E. A. Scott, 29 W. 39th Street, New York City.

COPIES OF JULY 4th, 1912, WANTED.

One of our subscribers is very anxious to obtain six copies of the issue of July 4th, 1912, and would be glad to pay 25 cents per copy for same. Will subscribers, who happen to have a copy of this issue and do not care to keep it, kindly send it into this office, and we will see to it that it is put in the hands of the right party?

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21098—December 2[illegible]—Extending, until June 30, 1914, time within which C.P.R. complete extension of existing siding for Quinlan and Robertson, in Lot 10, Con. 8, Tp. Huntingdon, Co. Hastings, Ont.

21099—December 27—Extending, until April 15th, 1914, time within which C.P.R. complete spurs for Moose Jaw Flour Mills, Limited, Moose Jaw, Sask., authorized under Order No. 20210.

21100—December 26—Approving location C.P.R. proposed station at Valor, on its Weyburn Westerly Branch, in N.E. ¼ Sec. 7-8-1, W. 3 M., Sask.

21101—December 26—Extending, until February 28th, 1914, time within which G.T.R. construct sidings for Otis-Fensom Elevator Co., Limited, at Hamilton, Ont., authorized under Order No. 20433.

21102—December 26—Relieving G.T.R. from providing further protection at crossing of highway east of Walkerville, Ont., known as Pellatt's Road crossing.

21103—December 23—Approving location G.T.P. Branch Lines station at Coalspur, at mileage 36.4, Alta. Coal Branch, Sec. 33-48-21, west 5th Mer., Alberta, station be erected in accordance with Co.'s Standard Structural Plan No. 1.

21104—December 22—Authorizing Algoma Eastern Ry. Co. to open for traffic its main line from mileage 79.80 to 80.80, and spur to station at Little Current from mileage 80.29 to 80.65, Ont.

21105—December 23—Suspending, for present, and pending investigation by Board, tariff C.R.C., No. E. 217, effective January 1st, 1914, increasing rates on pulpwood, in carloads, from points on the line of the Temiscouata Ry. to Riviere du Loup for local delivery.

21106—December 26—Authorizing Brandon Mun. Ry. Co. to operate its cars over crossing of C.N.R. on First St., Brandon, Man.; such cars to be flagged across by conductors of cars.

21107—December 29—Allowing C.N.R. to carry traffic over its railway between Avonlea and Gravelburg, Sask., a distance of 79 miles, until June 1st, 1914, subject to and upon condition that speed of trains over said line be limited to 20 miles an hour for first 26 miles and 15 miles for remaining 53 miles.

21108—December 27—Approving location Burrard Inlet Tunnel and Bridge Co.'s railway in city of Vancouver, from station 0.00 to station 130.03.6 on south shore of Burrard Inlet, B.C.

21109—December 27—Authorizing C.N.R. to construct across public road between Sec. 6-28-28, and Sec. 1-28-29, W. 3rd M., Sask., on its Alsask Southeasterly Line.

21110—December 27—Approving temporary diversion of G.T.R. Co.'s Seventeen Dist. Main Line tracks about 1 mile east of Merritton Station, Ont. 2. Approving plan showing superstructure of said temporary bridge to carry said diverted tracks over Welland Canal.

21111—December 29—Approving location C.P.R. station at Colborne, in Lot 32, Con. 1, Tp. Cramahe, Co. Northumberland, (East Riding), Ont., mileage 105.1 from Glen Tay.

21112—December 27—Authorizing Dominion Altantic Railway to open for traffic portion of grade revision of its line extending from a point on west side of St. George Street, Annapolis Royal, N.S., thence westerly to a point on west side of Allen's Creek, a distance of 2,790.5 feet; and use and operate bridge across Allen's Creek.

21113—December [illegible]—Authorizing C.P.R. to open for traffic double track from mileage 0 to 6, Medicine Hat Subdivision, Alberta.

21114—December 30—Authorizing C.P.R. to construct across highways at mileages 68.18, 69.44, 73.76, 165.95. 111.81, 112.88, and 115.05, Bassano Easterly Branch.

21115—December 29—Authorizing C.P.R. to construct spur for C. H. Richards, Saskatoon, Sask., subject to certain conditions.

21116—December 30—Authorizing Vancouver and Lulu Island Railway Company to construct branch from its railway at intersection of 3rd Avenue, Vancouver, thence along and across 3rd Avenue, and Granville Street for a distance of about 578 feet, to property of British Columbia Electric Railway Company, Limited, adjoining 3rd Avenue and Granville Street Bridge, and through said property to passenger and freight station proposed to be erected on said property, to be completed within 6 months from date of this Order, subject to conditions that Applicant do as little damage as possible and make full compensation to all persons interested for all damage done. 2. Also approving location of said passenger and freight station proposed to be erected on property of leased by British Columbia Electric Railway Company, Limited, in city of Vancouver.

21117—December 29—Amending Order No. 19256, dated May 13th, 1913, by substituting plans Nos. 55257 and 54122 for plan approved under said Order No. 19256.

21118—December 27—Rescinding Order No. 20941, dated December 3rd, 1913, in so far as it approved plan showing location Bassano Easterly Branch of Canadian Pacific Railway, from point in Sec. 22-26-23, W. 3 M., mileage 170, to point in Sec. 19-26-22, W. 3 M., mileage 173.

21119—December 29—Approving and authorizing clearances as shown on Canadian Pacific Railway plan showing minimum clearances of suspended signals in train sheds at Windsor Street Station, Montreal, Que.; provided men are kept off top and sides of cars while operating through said train sheds.

21120—December 29—Authorizing C.P.R. to reconstruct bridge No. 0.7 across Wellington Street, Sherbrooke, Que.

21121—December 29—Relieving C.N.R. of the speed restriction of 18 miles an hour over its Goose Lake Line, between Kindersley and Alsask, Province of Saskatchewan.

21122—December 30—Authorizing C.N.O.R. to open for traffic certain portions of its Toronto-Ottawa Line; authorizing it to use bridges on said portions; and limiting the speed of trains operated over said line.

21123—December 27—Authorizing C.N.R. to construct across Three (3) highways, namely:—1. between Sec. 11 and 10-28-29, W. 3 M.; 2. 31-27-28 and 6-28-28, W. 3 M.; and 3. Secs. 1 and 2-28-29, W. 3 M., Sask.

21124—December 29—Authorizing C.N.R. to construct spur for Huff Gravel Company, Limited, in River Lot 20, Penitentiary Grounds, Edmonton, Alta., and to cross Government Avenue with said spur.

21125—December 30—Authorizing C.N.R. temporarily, until July 1st, 1914, to carry traffic over Oakland Branch from mileage 42 to end of track, in province of Manitoba, distance of 12 miles; operation of trains over said line be limited to a speed not exceeding 12 miles an hour.

21126—December 29—Authorizing G.T.P.R. to construct main line across Government Road at mileage 397.4 Prince Rupert Easterly, in Sec. 9-11-5, Coast District, B.C.

21127—December 29—Suspending, for the present and pending investigation by Board, following tariffs:—C.P.R. Co.'s C.R.C. No. W. 1893, and Esquimalt and Nanaimo Ry. Co.'s C.R.C. No. 256.

21128—December 27—Suspending for present and pending investigation by Board, tariff C.R.C. No. 395, of Dominion Atlantic Railway Company.

THE COQUITLAM-BUNTZEN HYDRO-ELECTRIC DEVELOPMENT

HARNESSING THE WATER POWERS OF COQUITLAM AND BUNTZEN LAKES, BRITISH COLUMBIA—NEW HYDRAULIC-FILL TYPE OF DAM AT COQUITLAM —WESTMINSTER WATER SUPPLY—POWER EXTENSIONS AT LAKE BUNTZEN

By G. R. G. CONWAY, M. Can. Soc. C.E., M. Inst. C.E.
Chief Engineer, B.C. Electric Railway Company, Limited

THE Coquitlam Lake water power development is owned and operated by the Vancouver Power Company, Limited, which is a subsidiary company of the British Columbia Electric Railway Company, Limited, a company operating a railway, light and power business in the districts surrounding the cities of Vancouver and New Westminster, and the Fraser Valley, and also the city of Victoria and district on Vancouver Island.

The main features of the original power development, which were put into operation in December, 1904, consisted of a scheme connecting Lake Coquitlam with a lake known as Lake Buntzen by means of a tunnel through a mountain range 4,000 ft. high separating the two lakes, which has an elevation of about 400 ft. above the North Arm of Burrard Inlet.

At the outlet of Lake Buntzen a concrete dam was built 54 ft. high and 301 ft. long. From this dam originally four penstock lines were carried down 1,800 ft. to the power house, which is situated on a rocky bluff at the edge of the tidal waters of the North Arm. The original plant consisted of four 3,000 h.p. Pelton wheels, having an effective head of about 395 ft., and four 1,500 kw. Westinghouse generators.

Fig. 1.—General View of Coquitlam Dam During Construction.

Watershed.—The available water supply is derived from the Coquitlam watershed, which has an area of 105

sq. mi. The upper part of the watershed rises to 8,000 ft., and is covered with perpetual snow. Over this watershed the annual precipitation for the last eleven years has averaged 155 in. The maximum year during that period was in 1906, when the precipitation was 190 in. The minimum year was in 1911, with a record of 132 in. The maximum monthly precipitation is during the month of November. The average precipitation for November for the past ten years amounts to 28 in.; the maximum recorded rainfall during that period for the month amounts to 37¼ in.; the minimum recorded is 10.62 in. The minimum monthly rainfall is in July, the average for the past ten years being 2½ in. In the original project, Lake Coquitlam, which has an area of about 2,000 acres, was raised 11 ft., or from El. 432 ft. above sea level to El. 443 ft. The lake was raised by means of a rock-filled timber crib dam 169½ ft. in length, which was designed as an overflow dam, having a spillway 113 ft. long. The area of the lake formed by the old dam was 2,328 acres, and with the growth of the demand for electric energy, it was decided that practically all of the water running off from the watershed could be conserved if a dam were built at the outlet of the lake sufficiently high to store an additional 60 ft. of water, or a total depth of about 71 ft. that might be drawn down. Careful observation of the run-off data showed that slightly in excess of 1,000 cu. ft. per sec. was the average run-off for the whole year. This run-off represented about 78 to 80% of the recorded precipitation at Coquitlam Lake, and represents an average water storage of electric energy of 220,000,000

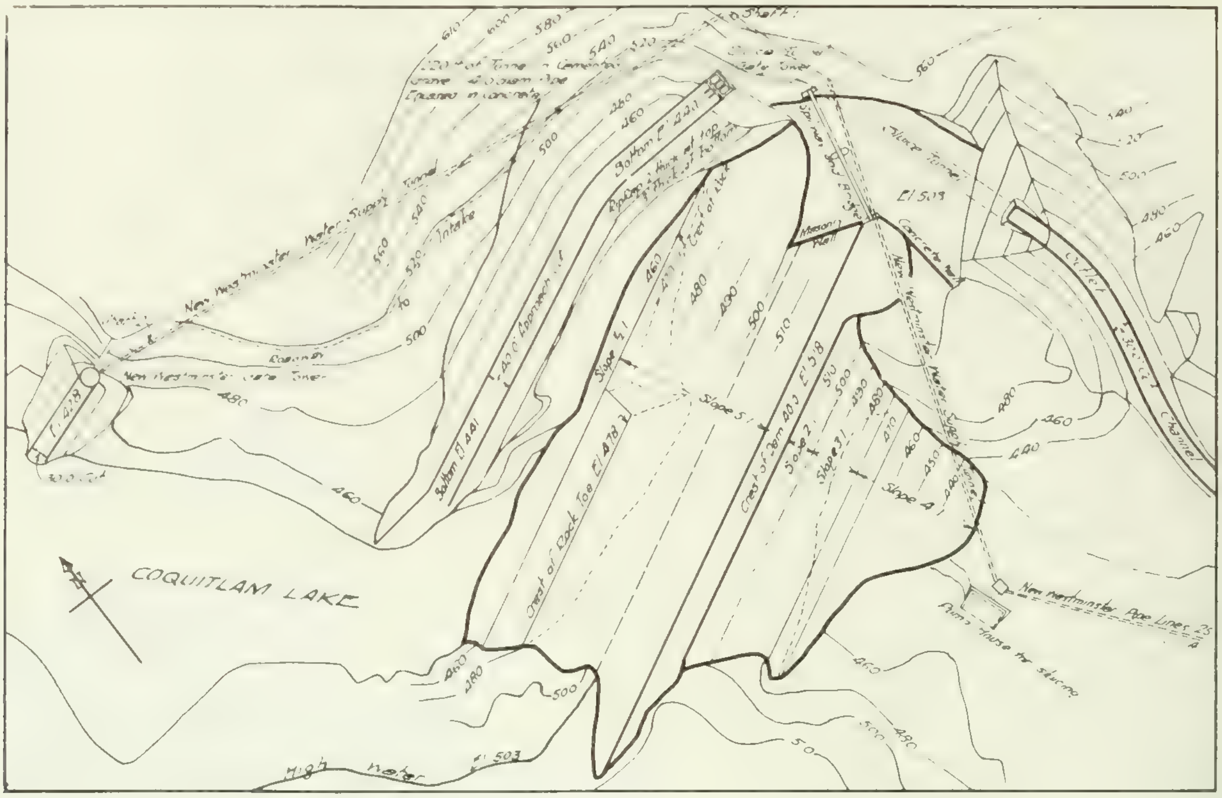

Fig. 2.—General Plan of the Coquitlam Dam, and Surrounding Development.

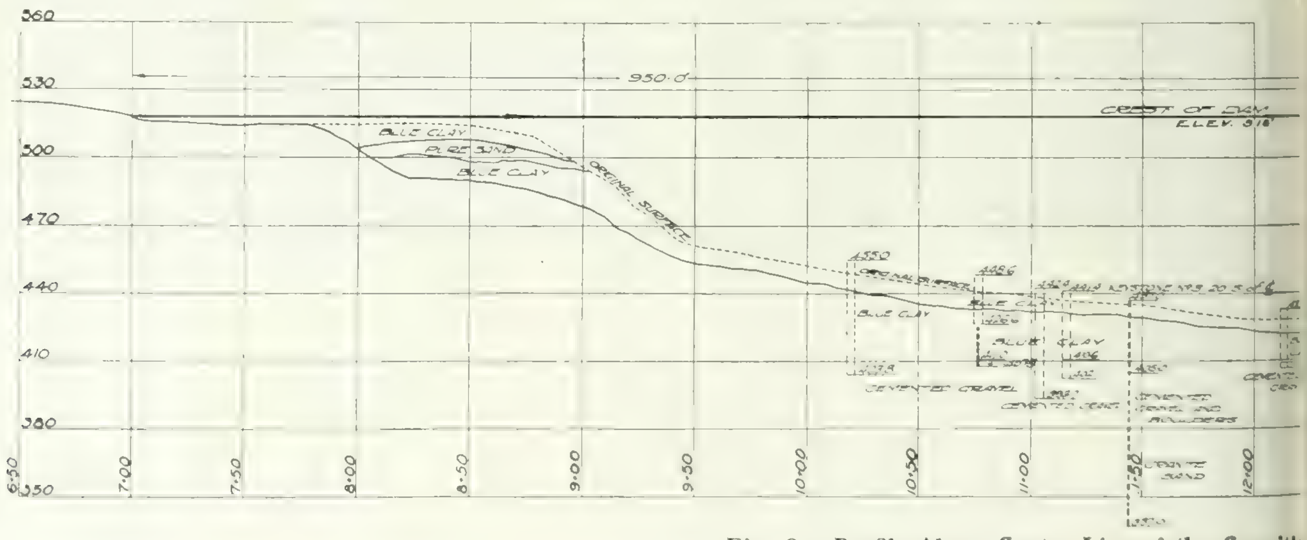

Fig. 3.—Profile Along Centre Line of the Coquitl

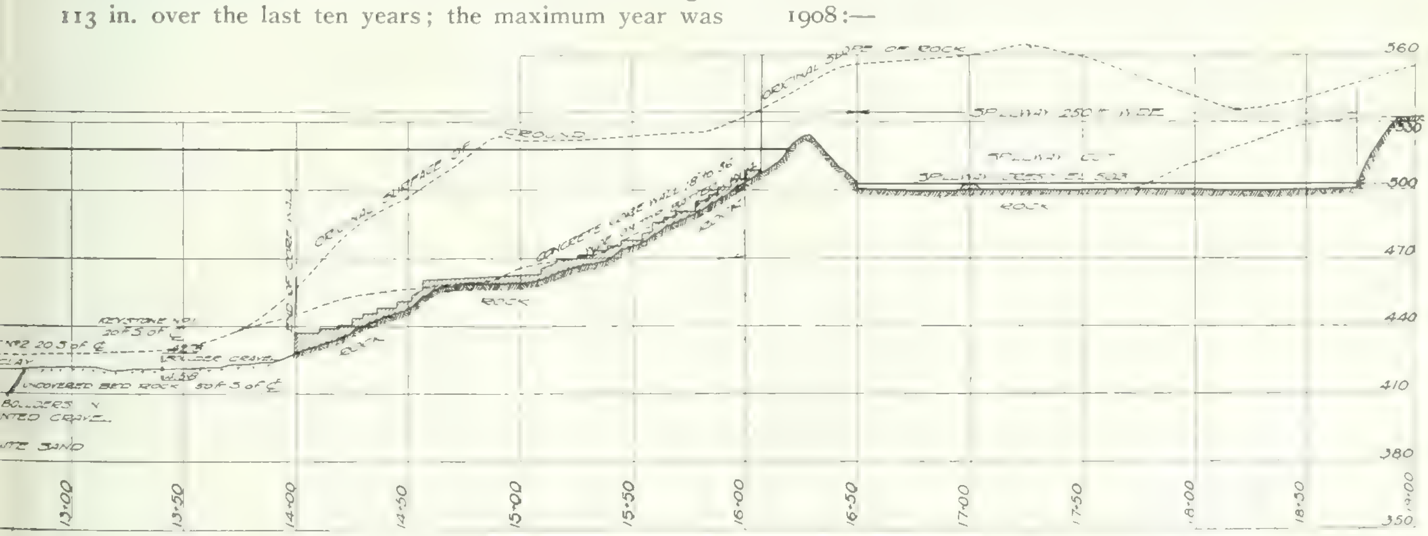
kilowatt-hours. To deal with this increased quantity of water it was necessary to enlarge the Coquitlam-Buntzen power tunnel, which originally had a cross-section of 81 sq. ft. and a capacity of 300 cu. ft. per sec., to 178 sq. ft. This work was completed in the spring of 1911, and the tunnel has now, when the lake is full, a maximum discharging capacity of 1,350 cu. ft. per sec. In addition to the water for Coquitlam Lake, Lake Buntzen, which has an area of 500 acres and a drainage of 7 sq. mi., has a considerable run-off. The rainfall at that lake averages 113 in. over the last ten years; the maximum year was 1906, when it was 137½ in., the minimum year 98½ in. 1911. The storage capacity of Lake Buntzen is 6,000 acre-feet.

The necessity of utilizing all the available water supply in Coquitlam Lake was due to the extraordinary growth which has taken place in the development of the City of Vancouver and surrounding districts during the last five years. The following figures represent the output of electric energy from the company's plants since 1908:—

Fig. 4.—Foundation Ready for Hydraulic Filling, Coquitlam Dam.



n, Vancouver Power Company, Limited.

1908-09	40,000,000	kilowatt-hours
1909-10	48,000,000	" "
1910-11	75,000,000	" "
1911-12	102,000,000	" "
1912-13	120,500,000	" "

It was therefore decided that the original plant which had been increased from time to time, bringing the total output up to 42,500 h.p., should, with the available storage in the Coquitlam Lake, be increased to a total of 83,000 h.p., so that the two plants could be operated satisfactorily as a peak load plant in conjunction with other plants contemplated by the company in the future.

Fig. 5.—Gate Tower at Diversion Tunnel, with Flash-boards for Temporary Water Storage.

New Dam.—A plan and profile of the new dam which is of the hydraulic-fill type with heavy rock toes, is shown in Figs. 2 and 3 respectively. The preliminary operations of building the dam were begun in the winter of 1908. Much exploration work was rendered necessary by opposition to the construction of the dam from various quarters, to determine the foundation conditions and also the location of rock for the purpose of driving a diversion tunnel for the floods. The result of the exploration showed rock in the east bank which dropped to an unknown depth one-third of the distance across the old river bed; abutting against this rock was a fine strata of blue and yellow impervious clay, making a perfect foundation for a dam of the hydraulic-fill type. The actual construction of the dam proper was not begun until March, 1912. The main dimensions of the new dam are as follows:—

Height of dam on centre line	99 feet
Extreme width of dam at base	655 "
Width at crest	40 "
Length of dam along crest, exclusive of spillway	950 "
Width of spillway	250 "
Elevation of spillway above sea level	503 "
Crest of dam above sea level	518 "
Slope of up-stream face	1 in 5
Slope of down-stream face	1 in 2 to 1 in 4
Original area of lake, old dam	2,328 acres
Area of lake at elevation 503 ft.	3,075 "
Storage capacity of lake above elevation 432 feet	192,100 acre-ft. or 8,369,000,000 cu. ft.
Storage capacity in electric energy at 78% efficiency	60,600,000 kw. hrs.

For the purpose of diverting the river and flood waters during the construction of the dam, a tunnel 490 ft. in length, having a clear width of 26 ft. with a height of 18½ ft. in the centre, was constructed on the east bank. This tunnel, which has its invert level at El. 435, was designed to carry 12,000 cu. ft. per sec. when the lake level was at El. 475, but the maximum quantity discharged through it did not amount during construction to more than 6,000 cu. ft. The maximum recorded flood over the old dam during the past ten years was 12,000 sec.-ft., or approximately 116 cu. ft. per sec. per sq. mi. of drainage area.

Gate House.—The gates for controlling the water through the diversion tunnel were placed in the concrete tower at the end of the approach channel. The bottom of the tower is at El. 455, spanning the tunnel entrance and supported on piers placed parallel to the floors in the tunnel. Girders were provided at the up-stream end of the piers for six temporary steel roller gates each 4 ft. 6 in. wide by 17 ft. high. These gates were controlled during the construction of the works by means of a gasoline hoist placed at El. 475 and arranged so that as the water rose in the lake they could also be operated at El. 508.

Upon the completion of the dam these gates were closed behind with a bulkhead of concrete filling up the whole space at the bottom of the tower, and forming a solid mass of concrete 26 ft. thick.

The tower, illustrated in Fig. 5, is rectangular in form, built up of three separate and independent compartments each 8 ft. by 11 ft. The main sluice gates are three in number, each five feet in diameter, faced with gun metal, and are designed to allow a certain quantity of water to pass down the river at any time for keeping

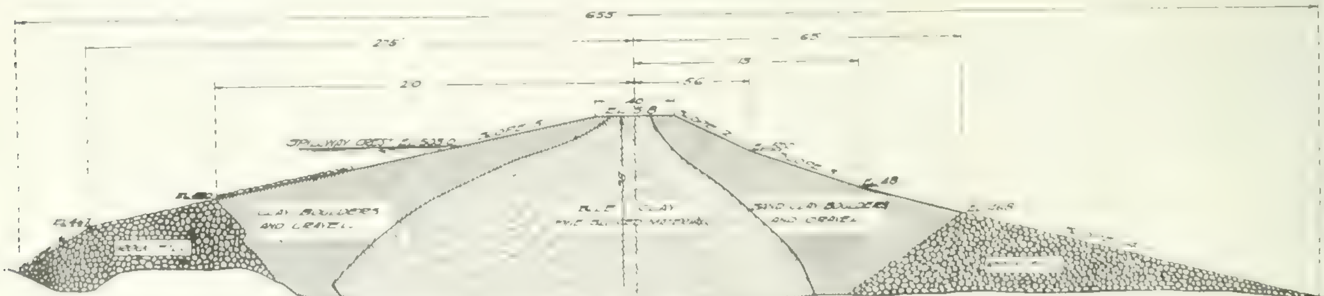


Fig. 6.—Coquitlam Dam, Maximum Cross-Section as Built.

it clean when required. These gates are operated at El. 513 within a gate house built at the top. The exterior openings to the three compartments are provided with auxiliary sluice gates made up of steel I-beams and timbers; but these will only be used when inspection of the main gates are necessary. Inclined racks are built against the front of these gates to protect them from water-logged timber and trash that might be drawn towards them when the gates are open.

In the construction of the works 1,150,000 cu. yds. of material were handled; this included the excavations for the approach channel to the diversion tunnel, and the outlet channel from the diversion tunnel and tunnel excavations.

The dam, as already mentioned, is of the hydraulic-fill type, the materials being sluiced by pumped water from borrow pits on the southwest and northeast banks of the river. Its cross-section is shown in Fig. 6.

Fig. 7.—A 70-ft. Trestle Over Spillway Cut, for Carrying Flume from N.E. Borrow Pit to the Dam.

The total quantity of material in the dam amounted to 544,710 cu. yds. In addition to this quantity about 40,000 yds. of material were sluiced in front of the old dam for the purpose of gaining additional storage during the construction of the work. Of the total quantity of material in the dam, 489,800 cu. yds. were sluiced from the borrow pits. In addition to this material there were 116,360 cu. yds. of heavy rock placed in position by hand and by cableways to form the rock-fill toes. The average quantity of material sluiced into the dam was 47,400 cu. yds. a month from October, 1912, to July, 1913, the greatest quantity being 77,700 cu. yds. during January, 1913; an average of 2,500 cu. yds. per day. The total number of days in which sluicing was carried on with two shifts of ten hours each was 296 days, included in which time were periods necessary for removing flumes.

The main flumes were laid on an average grade of 4%. These were carried on trestles of various heights reaching to a maximum of nearly 70 ft. One of these is illustrated in Fig. 7. The flumes were formed of two 12 x 1-in. planks in width, and 2 ft. 6 in. high, lined on the bottom with 6-in. hemlock blocks, a 1 x 6-in. plank being nailed inside along each side of the flume. The trestles supporting the flumes were formed of 6 x 6-in. posts, caps and stringers for the first deck, with 4 x 4-in. posts, 4 x 4-in. caps, and 6 x 6-in. stringers for the second deck. These trestles were placed 16 ft. apart, and very satisfactory results were obtained from the type of flume adopted. The lining of the blocks in the bottom of the flumes from the northeast borrow pit was renewed only once during the construction of the works, and the remainder required occasional patching only.

Ball bearing giants, 4 in. and 5½ in. in size, fitted and controlled by the Hendy deflector, were used under a pressure of about 80 lbs. per sq. in. at the nozzle. These delivered for sluicing operations 215,000,000 cu. ft. of water during the actual dam construction. The percentage of solids to water carried from the pits amounted to 6.14%, representing 5.36% of solid material as measured in place in the dam. For conveying the water to the monitors, 16-in. flange pipes in 17-ft. lengths were used. The labor costs of sluicing ranged in different months from 6 to 16 cents per cu. yd., depending upon the amount of work to be done in removing flumes.

The pumping plant consisted of two Dayton centrifugal 3-stage pumps with 10-in. suction, 8-in. discharge, working at 150 lbs. pressure, rated to deliver 4 cu. ft. per sec.; two Byron-Jackson, 3-stage, centrifugal pumps, 10-in. suction and 10-in. discharge, rated to deliver 7½ cu. ft. per sec.; one Worthington 3-stage centrifugal pump rated to discharge 4 cu. ft. These were driven by five electric motors having a combined capacity of 1,125 h.p.

Power was delivered to the dam for construction purposes at 34,000 volts and transformed down to the required voltage at the works.

Two electrically operated Lidgerwood cableways of 3-ton capacity were used for depositing the rock toes of the dam, one of 1,100 ft. span and the other 1,200 ft.

The clay from the borrow pits for the construction of the dam was a very finely stratified blue and yellow glacial clay mixed with a large proportion of gravel and heavy boulders. Samples taken from this clay in the pits showed it to have about 23 to 25% of moisture, and actual samples taken from the dam upon completion showed from 25 to 27%. The material forms the very finest clay concrete for the construction of the dam, and is absolutely impervious. Fig. 6 shows the approximate position in which the materials were placed as plotted for the monthly progress diagrams. The up-stream and down-stream slopes of the dam were very heavily rip-rapped with rock.

By reference to Figs. 6 and 8 it will be seen that the dam has been designed with unusually flat slopes and a

wide crest. This is due to the fact that the stability of the dam had to be such as to satisfy the sentimental objections of the population living below the dam, although these dimensions were entirely unnecessary from an engineering point of view.

The spillway, which is capable of discharging over three times the maximum recorded flood, was excavated on the east bank of the river in solid granite, about 90,000 cu. yds. of material being removed and deposited by the cableways to the rock toes. Over the spillway a steel bridge of two spans, each 125 ft. in length, has been constructed to form a continuation of the roadway over the dam to the Westminster intake tower.

Westminster Water Supply.—Lake Coquitlam has, since the year 1892, been utilized as the source of water supply for the City of New Westminster. A company called the Coquitlam Waterworks Company, formed in 1886, now owned by the Vancouver Power Company, sold to the City of New Westminster in the year 1889 certain rights in the waters of Coquitlam Lake for the purposes of the city supply, and the works were begun by the city soon afterwards. This supply was first drawn from Lake Coquitlam in the year 1892, from an intake which was situated on the west bank of the river near what was subsequently the site of the old crib dam. From this intake a 14-in. steel pipe main was carried to a distributing reservoir in the City of New Westminster. This main was sufficiently large to supply water for that city until 1912.

Fig. 8.—Coquitlam Dam and Spillway, Nearing Completion.

Under the agreement entered into between the Vancouver Power Company and the Department of the Interior of the Dominion Government the company undertook to carry out certain improvements for the protection of the Westminster water supply, and among other things that were agreed upon was the provision of the new intake tower situated 1,000 ft. north of the old intake on the east bank of the lake. From this intake tower a tunnel 1,940 ft. long was constructed, the greater part of its length, being in solid rock 4 ft. wide by 7 ft. high, with a concrete invert. In other portions where the tunnel passed through cemented gravels and clays, it was formed of 48-in. steel pipe backed with concrete. The intake tower is a heavy concrete tower which has its foundations on rock. The outlet of the tunnel is at El. 428, or 4 ft. lower than the lowest draw-off of the Coquitlam-Buntzen power tunnel, while the floor of the gate house on the top is at El. 518, corresponding to the crest level of the new dam. The intake tower is circular in plan, and has an inside diameter of 18 ft. top and bottom. The walls are 4½ ft. thick, from the bottom to El. 465, and then taper to 18 in. thick at El. 518. A concrete arch bridge connects the intake tower with the roadway on the shore. In the walls of the tower there are four 40-in. square openings fitted with cast iron gates, and cast iron screens on the inside, the exterior openings being protected with wrought iron screens. These openings are placed at El. 430, 451, 469 and 487, distributed around the outer wall of the tower. The copper screens are arranged so that they can be raised for cleaning purposes to a floor inside the tower placed at El. 508. In addition to the control of water from the exterior of the tower, a secondary control is obtained within the tower so that the water may be drawn off at any desired elevation. This intake consists of a standpipe 42 in. in internal diameter, built up in four separate sections, each section having conical seats on the upper and lower ends, and each section fitting to the one next below it. The bottom section rests on a special cast iron elbow set in the base of the tower. These intake pipe sections are guyed to 60-lb. rails placed on opposite sides of the pipe, and bracketed to the tower wall at frequent intervals. Lifting rods 1½ in. in diameter are attached diametrically opposite near the top of each pipe section. The intake is operated by hand by means of a special lifting gear which may be attached to any set of lifting rods. The openings into the intake pipe are at El. 433, 451, 473 and 481. To form the approach to the tower a channel was excavated within a cofferdam 20 ft. wide at the bottom with side slopes 1½ to 1, heavily rip-rapped with rock.

For the protection of the Westminster water supply the company carried out extensive clearing operations on the shores surrounding the lake, which were covered with a heavy growth of cedar and hemlock. For a distance of over three miles above the intake, the whole of the land to be flooded was cleared and the stumps sawn close to the ground. The clearing over this section was completely done to El. 508, and in the upper part of the lake the whole of the shores have been cleared to El. 480. The total area of land completely cleared amounts to approximately 750 acres.

This work proved enormously difficult, owing to the steep sides of the lake and the necessity of constructing rafts plated with steel for burning much of the debris. The cost of clearing has been upwards of $600,000. The lowest cost for clearing was about $350 an acre, while sections of the work in swamps where the timber was decayed and heavy, cost as much as $2,000 an acre.

The Coquitlam Lake water is of wonderful purity and is almost sterile. The following is a typical analysis of the water:—

Water Analysis—October 18, 1913.

(Parts per million.)

Physical Examination—

1. Turbidity	None
2. Reaction	Neutral
3. Smell	None
4. Taste	Good
5. Sediment	Slight
6. Color	30

Chemical Examination—

1.	Ammonia, free, expressed as nitrogen	.056
2.	Ammonia albumenoid, expressed as nitrogen	.07
3.	Nitrates, expressed as nitrogen	.06
4.	Nitrites	None
5.	Chlorine	3.24
6.	Hardness, total, expressed as CaO	2.20
7.	Hardness, permanent	1.40
8.	Hardness, temporary	.80
9.	Oxygen consumed, 4 hours at 37° C.	2.7
10.	Oxygen consumed, 3 minutes at 37° C.	.4
11.	Solids, total	18
12.	Solids, volatile	8
13.	Solids, fixed	10
14.	Poisonous metals	None

Microscopic Examination—
Vegetable fibres and crystalline matter.

Biological Examination—

Number of bacteria per c.c.	30.
Presumptive test for color bacilli	Negative

Samples of water have been carefully analyzed fortnightly during the past four years, and the number of bacteria per c.c. has varied from 15 to 100, but has averaged throughout the whole period of the work about 40 or 50 per c.c. In spite of the fact that over 800 men were employed upon the works, of whom nearly 600 were employed on lake clearing alone during some months, no pathogenic organisms were discovered at any time, a result due to the very careful sanitary precautions which were taken in connection with the construction of the works.

Power Plant No. 2, Lake Buntzen.—Owing to the fact that suitable foundations could not be obtained for extending the existing power house of a sufficient size to contain the new units, a new site was decided upon about 2,000 feet south of the existing power house No. 1, and there a new and independent plant has been constructed. The essential features of this new plant are shown in Fig. 9.

Water is obtained from Lake Buntzen through a concrete-lined tunnel 14 ft. 8 ins. internal diameter, and about 1,800 ft. long, driven through solid rock.

At the upper end of the tunnel three 6½-ft. Doble intake valves are provided, which are operated by oil pressure.

In order that better speed regulation of the machines may be obtained, and that the effects of water in the pipe lines due to sudden changes of load may be reduced, a surge tank is provided at the tunnel portal. This surge tank is 30 ft. in diameter and about 90 ft. high, and is built of riveted steel plates.

The pipe lines, of which there are three, are connected to the surge tank by means of reinforced plates. The upper ends of the pipes project into the surge tank, and are each provided with a bell-mouth, thus minimizing entrance losses. The pipes are 8 ft. 6 in. diameter and ½ in. thick at their upper ends, and taper to 7 ft. diameter at the power house, where the thickness is 1⅛ in. About 200 ft. from the power house the pipe lines pass into tunnels driven through rock, which is badly fissured. The slopes range from 28 to 53 degrees. A short distance below the surge tank, a Doble venturi butterfly valve is provided on each pipe line.

The power house building (Fig. 10) is of reinforced concrete construction, and is founded throughout on solid rock. On the main floor, 5 ft. above high-water mark, three hydro-electric units of a combined capacity of 40,500 h.p. have been installed. Each unit consists of one Dick Kerr 8,900-k.v.a., 3-phase, 60-cycle alternator, generating current at 2,200 volts, direct-driven at a speed of 200 r.p.m. by four Pelton-Doble water-wheels of the impulse type, the combined capacity of which is 13,500 h.p. The rotor of the alternator and the four water-wheels are all pressed onto a hollow nickel steel shaft 51 ft. 3 ins. long, and operated in one piece.

At the power house each pipe line divides into four branches, each branch supplying water to one wheel of the unit. On each branch a Doble hydraulically operated gate valve is provided, which controls the admission of water to two needle nozzles, which direct the water to the buckets of each wheel.

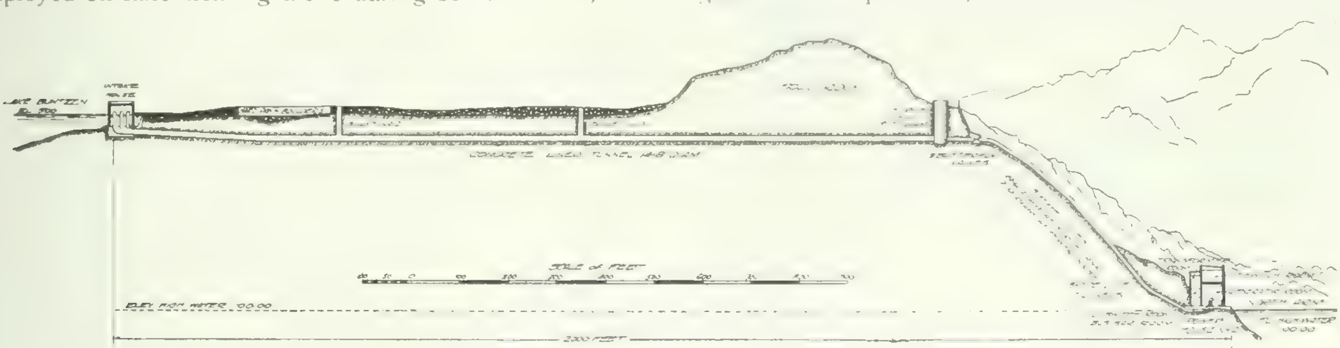

Fig. 9.—Lake Buntzen Power Development, Profile of Tunnel, Penstocks, Etc., of Plant No. 2.

The speed regulation of each unit is controlled by a Lombard governor, and two improved relief nozzles, which are controlled by the governor, are provided on each unit.

For excitation purposes, three 300-h.p. exciter units are provided. Each exciter unit is composed of a Dick Kerr induction motor generator set, direct-driven by two Pelton-Doble water-wheels mounted on the end of the shaft. The speed of the exciters is 600 r.p.m.

The excitation voltage is 250, and the voltage regulation on the A.C. bus bars is controlled by Tirrell regulators.

Owing to the great size and weight of some parts of the units, two 50-ton electrically operated travelling cranes are provided. These cranes control the entire length of the main generator room.

Immediately above the generator room is located the high-tension switch room, which also contains lightning arresters, etc. The high-tension switches are of the C.G.E. K-15 type, and are suitable for 60,000 volts. The lightning arresters are of the 4-tank electrolytic type.

To the rear of the generator room and above the bus bar compartments is the low-tension switch room; the low-tension switches are all of the C.G.E. H-6 type.

The transformer room is located immediately above the low-tension switch room. The transformer equipment consists of four banks of three 3,000-kw. single-phase, 60-cycle, oil-insulated, water-cooled transformers, by means of which the voltage will be raised from 2,200 to 34,000. At a later date the transformers will be "Y" connected, thereby increasing the voltage to 60,000. One 25-ton electrically operated travelling crane which travels the entire length of the transformer room is provided, together with the necessary oil tanks, oil filters and pumps. Current is fed to the lines through the above-mentioned K-15 high-tension switches.

Fig. 10.—Lake Buntzen Power House, No. 2.

HUGE DRY DOCKS.

If New York is not to be at a serious disadvantage as compared with the ports of Quebec and Boston, it must provide its own dry dock for the accommodation of the largest ocean liners. Both of the two ports mentioned are building dry docks capable of taking in ships of 1,000 ft. in length. It is interesting to learn, says the "Daily Telegraph," that the New York Dock Commission is planning to build a dock of this size at South Brooklyn. The dry dock to be built at South Boston is to cost $3,000,000, and a contract has been entered into by which the International Marine, the Cunard and the Hamburg-American lines will pay $50,000 a year for 20 years for its use. The announcement of the intention of the Nova Scotia Government to erect at Halifax a huge dry dock, one capable of receiving the largest merchant vessels and warships afloat, or, as it is stated, likely to be afloat, is certainly indicative of what the expectations of the business of the port are. It may be added that the large graving dock which the United States Navy Department is building at Pearl Harbor will be finished as originally planned. The chief difficulty in constructing the dock, which has now been overcome, is the shifting of the sand bottom.

THE TESTING OF BITUMINOUS MATERIALS FOR ROAD AND STREET CONSTRUCTION.

ONE of the papers presented at the 10th annual convention (Philadelphia, Dec. 9 to 12, 1913) of the American Road Builders' Association dealt chiefly with the testing of bituminous materials to be used in the construction, maintenance and repair of roads and streets. It outlined clearly the fundamental principles upon which such tests are based, and brought out the importance of the relation of these tests to paving specifications. The paper was read by Mr. Prevost Hubbard, of the Institute of Industrial Research, Washington, to the "Construction" division of the convention. What follows here constitutes an abstract of Mr. Hubbard's remarks. The reader is also referred to a discussion of the paper by Mr. Francis P. Smith, of Dow and Smith, chemical engineers, New York, which appears on another page of this issue.

For reasons that are not clearly apparent, the fundamentals of testing, in so far as they relate to the practical utilization of tests, have in many cases been overlooked by testing engineers and chemists in connection with bituminous road and paving materials. Disregard of these principles has undoubtedly created more confusion and misunderstanding on the part of highway engineers and contractors than any other one cause.

As applied to materials of construction, tests of both chemical and physical properties serve two main purposes. (1) As a matter of investigation, they constitute a record of the characteristics of the material examined. (2) When considered in connection with the behavior of a material in use, they serve as a guide for the selection of such material for future use.

In the matter of investigation it is often highly desirable that the greatest possible number and varieties of tests be applied to a material of construction, as by this means the most complete record of its characteristics are obtained. After considerable data of this sort has been secured on many lots of the same material, it is not as a rule necessary to make use of all of these tests in selecting such material for future use. Certain inherent and peculiar characteristics as determined by tests are, however, of value in the matter of selection, and such characteristics, when governed by quantitative limits, are made the basis of specifications for that material.

The ultimate utilization of tests for the purpose of selecting material for a given use makes it necessary that (1) the test limits adopted shall specifically define the material, and (2) that the material thus defined shall have previously proved satisfactory for that particular use.

For some classes of material these points are not difficult to cover. In the case of bituminous materials, however, the matter is complicated by the numerous varieties or types of bitumen in common use, and the overlapping characteristics of various grades of these different types. The interpretation of tests in general is therefore no simple matter, and numerous misconceptions of the value of certain tests are prevalent. Standards of more or less established test values have been thrown into question by the introduction of new types of bituminous materials which, while similar to or identical in many respects with other better known materials, yet differ from them materially in certain physical or chemical properties. This has made it necessary to either modify old standards or to create new standards to be used specifically for the new materials introduced. It is the

author's opinion that the latter method is in general to be preferred for reasons that will appear later.

The individual tests required by specifications for bituminous road and paving materials may serve one or more of the three following purposes: (1) They may directly indicate the suitability for a given use, of the material specified. (2) They may serve as a means of identifying the source of a material or even the material itself. (3) They may serve to control uniformity in the preparation or manufacture of a material.

The first of these purposes is undoubtedly the most important and is usually the only one considered by the lay mind. In the case of bituminous materials, this purpose is only partly accomplished by a comparatively few tests. As examples may be mentioned tests of constituency, such as the penetration test, the float test and the test for viscosity. Such tests can only be of maximum value, however, when applied to a specific type of bituminous material and when considered in connection with other tests, which, by themselves, may not directly indicate suitability. Thus, for a certain type of bituminous concrete pavement the proper penetration limits at 25° C. for a California asphalt may lie between 7.0 and 9.0 mm., while the proper penetration limits for a fluxed Bermudez asphalt to be used in exactly the same type of pavement and under the same conditions may be entirely different, say from 14.0 to 16.0 mm. It is evident that to attempt to cover the penetration limits for both materials under one specification would be useless. In the first place, such test limits as 7.0 to 16.0 mm. are so wide as to insure but little uniformity in different lots of the same materials; and, in the second place, an entirely unsuitable material of one class might be supplied under the maximum test limit of the other class. The fallacy of blanket specifications, which have already been advocated to a considerable extent, is thus easily demonstrated.

If a penetration test is essential under the conditions just mentioned, it is apparent that recourse must be had to separate type specifications; and if this is so the specifications must contain either tests or test limits which will describe certain peculiarities of the type specified, that are not common to other types. In many cases this cannot be done by means of a single test and two or more such tests will be required.

This brings us to a consideration of the second purpose previously mentioned, i.e., the use of tests as a means of identification. There are a number of such tests, among which may be mentioned specific gravity, melting point, solubility in carbon disulphide, fixed carbon, etc. So far as the usual test records are concerned, the specific gravity of a bituminous road or paving material is one of the most important characteristics used to determine its identity, and this is particularly true if its specific gravity is considered in connection with the consistency of the material and sometimes its solubility in carbon disulphide. Thus a bituminous material with a specific gravity of 0.99 and penetration of 7.0 mm., at 25° C. must be a blown product. Fluid consistency and high specific gravity, say 1.25, in a tar serves to identify it as a coal tar, and the identification is strengthened if its solubility in carbon disulphide is low, say 75 per cent. Numerous other examples of a similar nature might be cited and a treatise might be written upon the value of tests by themselves and in relation to other tests as a means of identifying bituminous materials.

High fixed carbon in most asphalt cements produced from Mexican petroleum is a distinguishing characteristic. Relatively low fixed carbon in good asphalt cements of the same consistency produced from California petroleums serve to differentiate them from the Mexican products. Here, again, the necessity or desirability of different test limits are apparent, for if the amount of fixed carbon yielded by a California asphalt cement was as high as the 16 per cent. often found in Mexican asphalt cements, indications would point very strongly to injury of the former due to excessive temperatures having been employed in the process of manufacture.

This leads us into the third purpose for which tests may be made to serve; control of uniformity in the preparation or manufacture of a material. Among such tests may be mentioned those for determining flash point, loss by volatilization, distillation, solubility in given grades of paraffin naphthas and solubility in carbon tetrachlorides. Practically all of the other tests previously enumerated may also be made to serve this end. No one by itself will, however, necessarily accomplish this purpose, no matter how close the test limits are drawn. This is mainly due to the fact that products of innumerably varied and complex characteristics may be produced from a given crude material by modifying the methods of manufacture.

Thus, by direct distillation of a given crude petroleum, an asphalt cement of 10.0 mm. penetration can perhaps only be produced by the removal of a considerable amount of distillate and the application of comparatively high temperatures. If distillation is discontinued in an intermediate stage, however, and the blowing process employed, an asphalt cement of the same penetration may be produced with the removal of much less distillate and the application of a lower maximum temperature. In the second case, the resulting product, while of the same consistency as the first, may have a lower specific gravity, a higher melting point, a greater penetration at low temperature, and a less penetration at high temperature. Other properties such as fixed carbon, naphtha, soluble bitumen, loss by volatilization, etc., may also be different. In such cases, control or assurance of uniformity in different lots of material must depend upon a number of tests, the interrelation of which is clearly understood, and for which suitable limits are specified.

In the preparation or interpretation of any specifications for bituminous road or paving materials, an appreciation of the interrelation of tests and test limits is as necessary as an understanding of the individual significance of the tests themselves, and yet those who should be most familiar with such matters often fail to consider the possible relations which a given test may bear to others with which it is associated in specifications. The interrelation of tests and test limits is something which the layman may not readily comprehend, and this has often resulted in his innocent acceptance and enforcement of unjustly discriminative specifications prepared or suggested by those who have an object to attain.

In the author's opinion, discriminative tests and specifications are perfectly proper and often desirable, if used in the right manner. They are, in fact, necessary to use, unless a more or less valueless blanket specification is adopted. When so used, however, their significance should be clearly apparent and they should not be put forward as open specifications.

When a given type of bituminous material has a single characteristic property which distinguishes it from other types, test limitations of this property may be so drawn as to make a specification discriminative. The status of such specifications is not usually difficult to ascertain. Discrimination is, however, sometimes secured by the use of a combination of two or more test limita-

tions, the significance of which is only apparent under the close scrutiny of one who has an intimate and comprehensive knowledge of all types of bituminous materials. Specifications of this class may, as a whole, absolutely eliminate competition, although no single clause in the specifications could be criticized from this standpoint.

If competition is eliminated by a single specification, as is sometimes advisable or even necessary, in order to insure a satisfactory product, it may often be restored by the use of two or more specifications which will serve as alternatives. When this is done, two or more types of bituminous materials will be specified, which are of equivalent value in so far as their suitability for a given use is concerned. Thus while different test limitations and sometimes different properties are covered by the different specifications, each particular combination of test limitations and properties, constituting a given specification, will be considered as equivalents.

From the foregoing discussion, it must be evident that the preparation of specifications for bituminous road and paving materials is often a complicated matter and should only be undertaken by one who has thoroughly familiarized himself with the origin and manufacture or preparation of all types of bituminous materials as well as with their physical and chemical characteristics. It is the author's experience that comparatively few highway engineers in this country are sufficiently acquainted with these materials to warrant them in preparing such specifications. Many who have attempted the task have failed because of lack of accurate information which has led them to combine and make use of portions of specifications prepared by others. Such combinations have most often proved utter failures, some of which are ludicrous, inasmuch as they have actually defeated the object for which they were presumably drawn. Others have been impossible because of the fact that certain clauses or test limitations prescribed were incompatible.

In this connection it may be said that while the average highway engineer will not find it practicable or even necessary to also become a highway chemist, he should nevertheless possess as a part of his practical working equipment some knowledge of the chemical and physical properties of bituminous materials and methods of testing them. A lamentable lack of such information is apparent in many highway engineers who, in other branches of their profession, are thoroughly capable and efficient. Opportunities for obtaining instruction along this line are now being offered by at least one of our universities, and many engineers should find that the comparatively short time required for this purpose could not be spent to better advantage.

One other point may be mentioned regarding the preparation of specifications which is directly connected with test limitations, and this is the matter of allowable variations in results which may be looked for from different chemists and different laboratories. In the first place it should be remembered that at the present time there are comparatively few standard methods for making tests which have been generally adopted. Variations in results are frequently attributable to variations in methods of testing. It is, therefore, good practice to include in, or as a part of specifications, descriptions of the methods to be employed in testing. This is especially true where specifications are to be widely used.

Besides the above mentioned cause, a certain variation in results may be expected from what is termed the personal question. Thus, no matter how clearly defined a method may be nor how conscientiously followed, it is the exception rather than the rule when two operators working on samples of the same material obtain exactly the same results. In fact, a single expert operator will seldom check himself exactly, although his results may be identical in so far as their practical application is concerned. Moreover, it should be realized that in substance as complex in character as are bituminous materials, however carefully prepared or manufactured, there is apt to be some variation in samples of the same batch whether taken from the same still, tank, kettle, barrel or even from the same sample can.

Just what the allowable variation in results should be when all of these conditions are taken into consideration, is a lengthy matter to discuss. It is certainly not the same for all tests, nor even for the same test applied to different classes or grades of material. Thus in the ordinary volatilization test a variation of 1 per cent. in results obtained upon a material losing 15 or 20 per cent. would be perfectly reasonable, while in a material losing 2 per cent. it would be an inexcusable variation. Owing to lack of time, the author does not consider it advisable to attempt a detailed discussion of this subject in the present paper, but suggests it is a topic for consideration.

In conclusion, the author wishes to state that while this paper may appear to deal with specifications in general more than with the actual testing of materials, it should be remembered that specifications are, in effect, definitions, and that from a broad standpoint definitions are themselves fundamental tests.

TRENT VALLEY FOREST RESERVE.

The Commission of Conservation is recommending that the 2,000 square miles of land in the Trent Canal watershed be set aside by either the Dominion or Provincial Governments as a forest reserve. Such a protective measure would under the peculiar circumstances, seem to be well advised. The water supply for the Trent Canal and Kawartha Lakes is obtained from the watershed mainly, and would be seriously impaired if the area in question were denuded of the remaining timber. Since the Dominion Government in 1905 obtained control of the water rights, much valuable work in damming up the back lakes has been done, with the result that the flow of water for power purposes north of Peterborough has enlarged most satisfactorily. The Dominion has spent over ten millions already on the Trent Canal, and by the time the extensions to Georgian Bay and Lake Ontario are completed it will have spent several millions more. And further, there are cogent reasons beyond the water-conservation interest to support the commission's recommendation. Half of the area is now unpatented, or in possession of the Crown. Only a tenth of the land can be farmed, and the farming at the best is so poor as to be quite unprofitable. Less than 700 acres of a million acres of forest is untouched virgin area. Under the provincial order-in-Council of 1905, conveying to the Dominion the water control, the right to buy land along the lakes and water courses at 50 cents an acre was granted the Dominion Government, but only two thousand acres were bought. It seems obvious that the best interests of the district, as well as the requirements of a wise conservation policy, would be served by making the areas in question a reserve for afforestation purposes

The production of coal in Italy in 1912 was 663,812 metric tons, of which 660,491 tons are classed as lignite. Imports were 10,057,228 tons; exports, 26,288 tons. The coke made —largely from imported coal—was 1,223,902 tons; briquettes, 874,365 tons.

DISCUSSION ON MR. PREVOST HUBBARD'S PAPER, "THE TESTING OF MATERIALS FOR ROAD AND STREET CONSTRUCTION."

By Francis P. Smith.

WHILE the speaker agrees with much that Mr. Hubbard has said, he does not consider that his objections to the so-called blanket type specifications are valid, more especially with respect to asphalts. The asphalt paving industry is by no means a new one. For upwards of forty years pavements and roadways of this type have been in use in this country. The speaker has for eighteen years been closely identified with this industry, and during that period has had charge of the mining and refining of asphalts and the laying of bituminous pavements of all kinds, and he, therefore, believes that he is qualified to judge, and justified in stating that the requirements of an asphalt for paving purposes are well understood and are comparatively simple and have nothing to do with the sources of the material. For specification purposes he considers that so-called identification tests are unnecessary.

The function of an asphalt cement or asphalt binder is to cement together the particles of the mineral aggregate which forms the roadway. In order to do this it must be possessed of sufficient cementitiousness or binding value. If it fails in this, it is useless as a cementing material. It must be sufficiently pure; i.e., contain sufficient bituminous binding material, to make it available for use. It must be of such a consistency that it can be properly applied to the mineral aggregate in such a way as to thoroughly coat each particle of it. It must not be too susceptible to changes in temperature; i.e., become too hard in winter or too soft in summer. It must not harden too rapidly when heated in the melting kettles and when exposed to the elements it must maintain its original properties for a sufficient length of time to give satisfactory service in the pavement or roadway. All of these properties are determinable by well known tests, and these tests must be met by all asphalts before they can be considered suitable for paving or road making use. It is true that different asphalts vary in their properties. Some are purer than others; some are more susceptible to changes in temperature or to prolonged heating, and some have higher cementing value than others. Experience has shown that a suitable asphalt for paving purposes need not possess all of these qualities in the highest degree, but sufficiently so for practical purposes. From past experience, however, it is perfectly possible to clearly define minimum limits which all asphalts must pass in order to be accepted with safety for paving work. Having done this, you have established the ideal specification of the blanket type which calls for all the necessary qualities and does not differentiate as to source, but as to quality only, and is not of excessive length. This fulfils the first purpose of a specification for bituminous road and paving materials as defined by Mr. Hubbard. Except in special cases, just why a specification should state at great length a number of tests for identifying the material, as stated by Mr. Hubbard to be the second purpose, the speaker fails to see. Anyone really competent to test bituminous materials for paving or roadmaking purposes can identify them just as easily without a specification as with one and certainly the contractor does not require this information to enable him to bid intelligently.

As to securing uniformity in the preparation or manufacture of a material, it would seem to be a simple task to insert a clause in a blanket type specification stating the maximum permissible variation in different shipments of the same class of material. To further insure that one manufacturer shall not adulterate or lower the quality of his material in any respect or respects so that it will **just** meet the minimum requirements of the specification, it may be required that all shipments of material shall be fully equal to the established standard and recognized quality of that particular brand.

Mr. Hubbard uses the variations in desirable consistency of different asphalts as an argument against blanket type specifications. Assuming that the wide variations which he cites are altogether normal, these are by no means wholly dependent upon the source of the asphalt. The considerations which affect desirable consistency or penetration are:—

1. Purity.
2. Susceptibility to changes in temperature.
3. Character of mineral aggregate.
4. Climatic and traffic conditions.

As to purity, the fluxed Bermudez which he cites contains about 96 per cent. of bitumen, the California about 100 per cent. of bitumen. There is too little difference in this respect to afford an excuse for separate specifications.

As to susceptibility to changes in temperature, the California is much more affected by temperatures up to 140° F.; i.e., softens more readily but, on the other hand, loses less when heated to 325° F.

The character and grading of the mineral aggregate, however, have as great an influence on the desirable penetration as the susceptibility of the asphalt to temperature changes.

The climatic and traffic conditions for any one particular piece of work will be the same in each case and may, therefore, be dismissed from consideration.

Until the material is actually assembled, however, it is impossible to state with certainty just what will be the proper penetration or consistency of the asphalt cement or binder, as it is impossible in most cases to draw a specification which will call for a mineral aggregate possessing a predetermined and definite degree of stability, and upon this the desirable consistency of an asphalt cement or binder largely depends. This consistency is something which the trained and experienced engineer can and should determine while the work is in progress. While this argument applies more forcibly perhaps to sheet asphalt pavements than to asphalt macadam, it is neverthelesse true of both types of construction and may be readily met by a clause in the blanket type specifications to the effect that the exact degree of penetration or consistency within the limits established by the specifications shall be determined by the engineer in charge, depending upon the kind of materials used and the traffic upon the roadway to be paved.

On the other hand, let us assume that a separate specification is to be prepared for each kind of asphalt. Those commonly in use are prepared by refining or fluxing, or both, Gilsonite or crude asphaltic material obtained from California, Cuba, Mexico, Texas, Trinidad and Venezuela. All of these differ essentially in purity and susceptibility to changes in temperature, and from the standpoint of consistency or penetration should, therefore, according to Mr. Hubbard, be considered separately. This would make seven separate specifications. In the case of Gilsonite, the character of

an asphalt cement or binder made from it would depend entirely on the kind of flux used with it, so that Gilsonite products alone might require two or more specifications. The same is true from the road binder standpoint of Trinidad, Cuban and Bermudez, while with California and Mexican asphalts the method of distillation used greatly affects the character of the product. In fact, the New York City paving specifications call for a special type of California asphalt much less ductile and susceptible to temperature changes than the standard California paving asphalt which has been successfully used for many years throughout the United States and is exclusively used on the Pacific Coast. Again, what is to hinder any manufacturer from combining two or more of these asphalts, as has been successfully done in many cases? To carry the separate specification idea, therefore, to a logical conclusion would involve the writing of an encyclopedia which would need constant revision and to separate the materials into two or three classes would be a poor compromise, leading to invidious distinctions, in many cases perhaps even to unfair discrimination, as it has done in the past. Such a compromise would, in the speaker's judgment and experience, be far worse than anything which has been alleged against the blanket type of specification.

In the early days of the paving industry closed specifications and high prices were the rule. As knowledge and experience in the paving industry have been acquired by engineers, closed specifications have become more and more rare and under proper blanket type specifications price has declined and quality has been maintained. The type brand of specifications were tried and abandoned as too cumbersome and the speaker freely admits that some years ago he advocated and drew a number of such specifications, but later became convinced that they were unnecessary and cumbersome and so abandoned them.

The Fixed Carbon Test.—With regard to the fixed carbon test,* the speaker considered that this is solely an identification test and therefore has no place in a specification unless it is desired to call for a particular kind or type of asphalt. This, as Mr. Hubbard states, may be perfectly proper in certain instances, but not in a specification where open competition is desired.

Many excellent pavements have been laid with California asphalt containing 16 per cent. and even 17 per cent. of fixed carbon, and it may, therefore, be considered at least doubtful whether the presence of this amount of fixed carbon in California asphalt is a sign that it has been injured in the process of manufacture.

The specific gravity test is undoubtedly of value as an identification test, but it is perfectly possible to recognize a blown asphalt without having recourse to this test, as, for instance, by the use of the ductility test. It is also questionable whether a certain amount of blowing is not the reverse of injurious so long as the ductility or cementing value is not reduced too greatly. Air blowing during distillation reduces susceptibility to changes in temperature and within limits and for certain purposes this is highly desirable.

A word with regard to the paraffine test.† The speaker believes that it has been conclusively proven that the presence of paraffine scale per se does not necessarily injure asphalt for paving purposes up to, say, 10 per cent., and possibly beyond that. The advocates of this test have recently taken the position that it is valuable as indicating the presence of an undesirable amount of paraffine hydro carbons in an asphalt, oils consisting largely of paraffine hydro carbons being recognized as unsuitable for the production of asphalt. To dispose of this claim it would seem to be only necessary to cite the case of many old and excellent pavements laid with Trinidad and other asphalts which contained over 25 per cent. of a flux composed almost wholly of paraffine hydro carbons. If 25 per cent. of paraffine hydro carbons is not injurious, where is the line to be drawn? It seems only reasonable to relegate this test to the class in which it really belongs, viz., the identification class, and rely on tests measuring the essential qualities of an asphalt when it comes to determining its fitness as a paving or road making material.

With regard to the ductility test, this has frequently been criticized by those who apparently do not understand its true scope or function. It has been claimed that the most ductile materials at ordinary temperatures, say 77° F., are those which are least ductile at low temperatures. This is not true. Great care must be taken in making ductility tests at low temperatures, otherwise the briquette will crack and no ductility will be reported. What is true is that the most highly ductile materials lose relatively a greater proportion of their ductility at low temperatures than do low ductile materials, but it must be remembered that even at 77° F. the latter class have practically no ductility to speak of. In the speaker's experience and in that of many others, the ductility test more nearly measures the cementing value of an asphalt than any other test known, and it is in that that its chief value lies. In this connection I will quote some remarks recently made by Mr. C. N. Forrest, of the Barber Asphalt Paving Comany, concerning the ductility test:—

"There is another fallacy in connection with the ductility test. It has been asked why should not the material be ductile at thirty-two degrees Fahrenheit, the supposition being that when a pavement expands and contracts, the resistance of the asphalt, under those circumstances, is dependent more or less on ductility, but the ductility test as performed according to the general way of doing it, as we know it, is a measure of the cementitious value. To produce a material that is ductile at thirty-two degrees Fahrenheit is to produce a short material; that is, if it is ductile at 32, it is not ductile at 77, and that would be done by the same method as increasing the toughness—by using a blown oil.

"The ductility test has nothing whatever to do with the capacity of the asphalt to give and take with the expansion and contraction. As a matter of fact, the asphalts which are rubbery and show some resistance to impact and show some ductility at a low temperature, will seldom show enough for sheet asphalt. They will crack in cold weather, although they are rubbery and show resistance to temperature changes."

As to variations in results as mentioned by Mr. Hubbard, the writer has often seen determinations reported in hundredths of a per cent. when the method employed was not accurate within tenths of a per cent. In similar cases he has also known material to be rejected because it exceeded the specification limits by two-tenths of a per cent. where the method used was not accurate within one-half of one per cent.

In conclusion, the speaker wishes to most heartily concur in Mr. Hubbard's statement as to the necessity

*See The Canadian Engineer, Vol. 25, pp. 703, 738, 780, 801, 808, and 872.

†See The Canadian Engineer, Vol. 25, p. 838.

for an understanding of the individual significance of the various tests and the relations of the different tests to each other. Without this knowledge the preparation of proper specifications and the interpretation of them is impossible.

INFLUENCE OF THE POSITION OF CROWN HINGE ON THE WEIGHT AND DEFLECTION OF A THREE-HINGED SPANDREL-BRACED ARCH.

THE form of three-hinged spandrel arch most frequently used in bridges is that in which the crown hinge is placed in the lower chord. Often, however, the crown hinge is located midway between the upper and lower chords, or in the upper chord, the weight and deflection of each member varying with different positions of the hinge. Just what the variation is in each case is given in a brief form by Messrs. M. A. Beltaire and R. W. Parkhurst in *The Cornell Civil Engineer* for December, 1913. Their results are from a series of investigations to compare the weights and deflections of three-hinged metallic arches as influenced by the shifting of the crown hinge from its ordinary position in the lower chord, to a position intermediate between the chords, and finally to the upper chord. These three positions are designated in the following as Case B, Case I and Case T respectively.

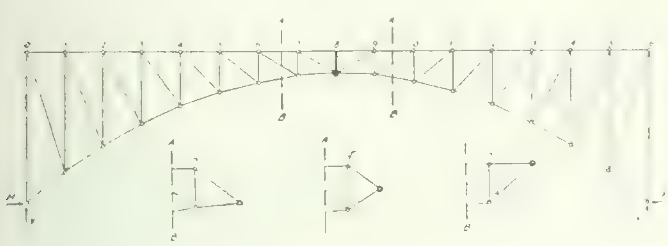

Fig. 1.—Three-Hinged Arch Bridge.

In conducting these investigations it was not thought necessary to work out a new design of a three-hinged metallic arch, a sufficient field for investigation being furnished by a study of the design of the Niagara spandrel-braced arch. This arch has a main span 550 feet long, supporting at each end a trussed span of 115 feet. The form of the main arch is as shown in Fig. 1. Each truss has a batter of 1 horizontal to 10 vertical, with a width between the axes of the upper chord of 30 feet; this makes the axes of the rib 34 feet apart at the crown and 56 feet 7.75 inches at skewback centres. The axis of the rib at the centre is 113.9 feet above the skewback line as measured in the plane of the truss.

Influence on Weight of Truss.—The investigation of the influence of the position of the crown hinge on the weight of the structure, conducted by Mr. Beltaire, was carried out by computing the maximum, minimum and reversed stresses for each member graphically and then computing the required section areas. The area for dead load was found separately from that for live load and to the latter was added 80% of the reserved stress.

In computing the weight of members, the theoretic weight was used, i.e., the weight as computed from the formula

$$W = 3.4 A l$$

in which W = weight of member; A = area of section in square inches; l = length of member in feet and 3.4 = weight of steel bar one foot long and one square inch in cross-section. This ignores all latticing and details at joints and hence it is but a very close approximation; experience shows that this theoretic weight is slightly less than the actual weight, the ratio of actual to theoretic weight averaging about 1.25.

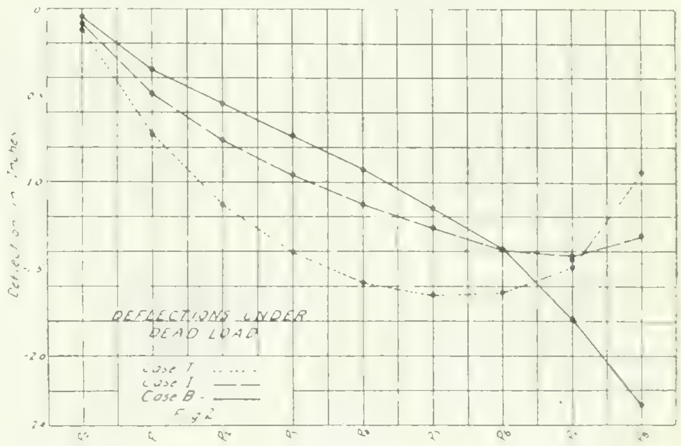

Fig. 2.

The weight of the structure in Case B was found to be 3132.96 kips, of which 12.9% was for the weight of upper chord members, 43.4% for lower chord members, 20.1% for the diagonals, and 23.6% for verticals. The weight in Case I was 2857.616 kips, as follows: Upper chord members, 13.2%; lower chord members, 36.9%; diagonals, 24.8%, and verticals, 25.1%. The weight in Case T was 2762.588 kips, as follows: Upper chord members, 19.1%; lower chord members, 32.8%; diagonals, 23.3%, and verticals, 24.8%. The weight in Case T was 88.17% of that of Case B and Case I 91.21% of that of Case B.

Conclusions.—From the above it is seen that Case T is the most economical design where a three-hinged arch is to be erected, it requiring 11.83 per cent. less material than Case B and 3.4 per cent. less than Case I. In a structure of the magnitude of the arch used for the computations, the economical advantage would amount to

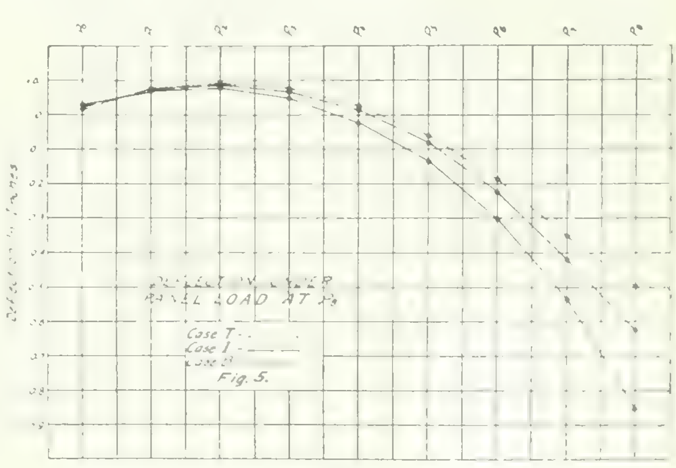

Fig. 3.

about $11,000, or $1,000 for each gain in per cent. The great gain made by Case T was caused by a clause in the specifications in regard to reversal of stress; in this case there was no reversal of stress in the upper chord members, while in Case B every member was reversed; the

same thing was true for the diagonals and verticals with the possible exception of one or two members in each set. Therefore, if the design were made under a smaller factor than 80 per cent., Case T would not be as large.

In view of the above, the writers claim it is only fair to state that where three-hinged spandrel arches are to be designed, Case T will be the cheapest and most advantageous.

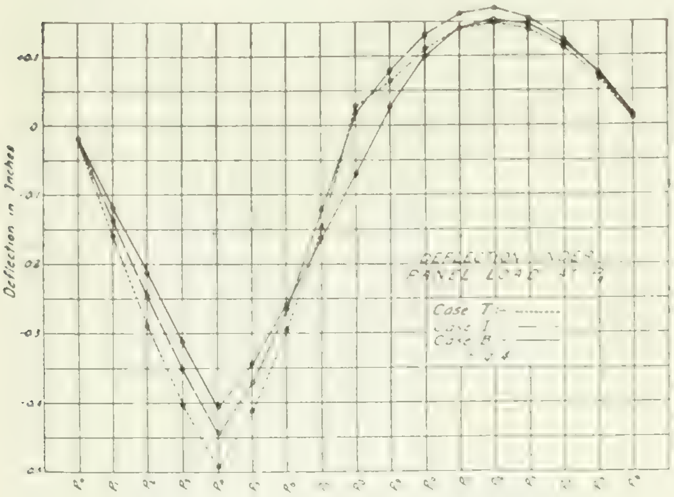

Fig. 4.

Influence of Deflections.—The stresses, sections, etc., which were found in the first study for a comparison of weights were used by R. W. Parkhurst to find deflections. Four cases were considered, those under dead load, full live load, and concentrated panel loads at the quarter points and middle of the span respectively. The stresses due to the load P_4 were computed directly by the analytic method and those for the loads P_8 and P_{12} were found by the graphic method. From the stresses and given sections, the elongations were computed and deflection diagrams drawn. The results are given in the form of curves in Figs. 2, 3, 4 and 5.

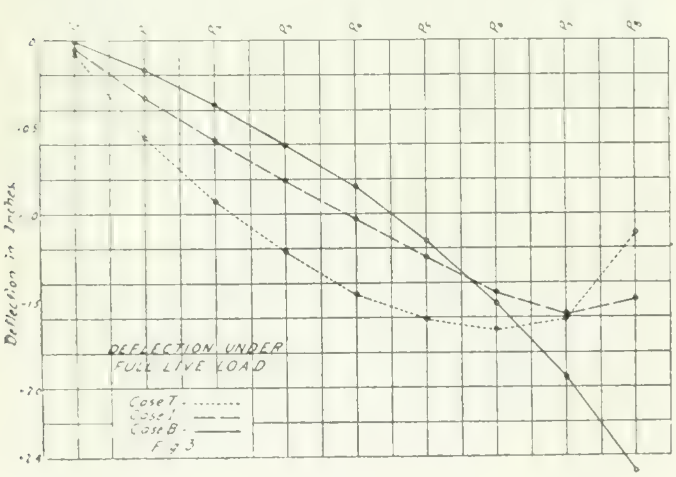

Fig. 5.

Conclusions.—Examination of the curves indicate that under dead load and full live load, Case B possesses greater stiffness at the quarter point than the other types, but deflects considerably at the centre. Case I shows good average values of deflection, while Case T shows great deflection at the quarter point, but comparatively little at the centre.

For the load at the quarter point, Case B shows greater stiffness throughout, while Case T allows considerable deflection under the load, but about the same amount of upward deflection for the unloaded half of the span, as Case B. Case I indicates average deflection under the load, but greater upward deflection. Both Cases I and T remain about stationary at the centre.

Under the load P_8, Case B shows greater deflection than the other types, Case I again ranking as intermediate.

From the preceding results, Case T shows considerable deflection in all cases except under the load P_8, while Case I seems to give the best average throughout. Case B is not considered on account of its comparatively great weight as shown above. For extremely light loads, Case T might be employed on account of cheapness of material, but since Case I is but 3.4 per cent. heavier, the extra cost should not be great, and where the loads are larger, and where additional stiffness is required, the latter arrangement might well be employed to advantage.

ELECTRICITY IN INCINERATOR OPERATION.

THE municipal incinerator just accepted by the city of Pasadena, Cal., has at least one electrical feature that is unique, a system of four elevators which receive the loads from the dump wagons at the ground level. These cars are of iron and each has a capacity of about two tons. The dump wagons shoot their loads directly into the elevator car, which is set with its upper edge flush with the floor, as shown in Fig. 1. The car is then hoisted by electrical power to the top story of the building, running between upright tracks. At the top these tracks are curved in such a way as to turn the car almost upside down, leaving it at an angle

Electric Elevator for Receiving Garbage.

of 45° with its mouth below the base and flat against the furnace door. The door is then hoisted, also by electrical power and the contents of the elevator are shot into the furnace. Besides this automatic dumping device, the fan which adds to the draft of the 152-foot smokestack is electrically operated, while, of course, the lighting is electrical. Current is obtained from the municipal lighting plant, which is only 500 feet distant. It is charged against the incinerator account, and costs about 25 cents a day for operating the hoist and about $1.50 a day for operating the blower. In constructing the incinerator, it was planned to install a large boiler on the top floor to take advantage of the resulting heat from the furnaces and generate steam power to be delivered to the city lighting plant, but this plan has not been carried out as yet. The incinerator is a reinforced concrete structure,

costing $46,000 and has a capacity of 30 tons of garbage a day. It is of the Fredsmith type, and depends largely upon the dry rubbish delivered as a fuel to destroy the wet refuse.

GARBAGE DISPOSAL COSTS.

THE question of garbage disposal has reached an acute stage in Chicago, the dispute between the city and the former contractor for disposal and the inability of the city authorities to decide upon new methods of disposal have continued until the old contract expired and have resulted in a refusal of the contractor to continue pending settlement of the question, so that now the property owners are begged to dispose of the garbage as nearly as possible upon their own premises, and the city is treating with chemicals what it must collect before dumping it in abandoned clay holes.

The discussion has resulted in the presentation of much information of greater or less value upon the comparative values and costs of various methods of disposal. The following information, from "Municipal Engineering," is derived from comparative estimates made by M. de Ronore, of Paris, France:—

An assumption of 1,000 tons of material for disposal per day is made, of which, according to the Parisian average, 40 per cent. will be garbage and street sweepings and 60 per cent. dry, combustible rubbish. The average cost for incineration of wet garbage is said to be $2 a ton and that of incinerating a mixture of equal parts of dry waste and wet garbage over 50 cents a ton. The dry, combustible rubbish has a calorific value one-fifth that of good coal, while the mixture with garbage has no calorific value.

The mixed method of garbage disposal produces a fertilizer weighing about 20 per cent. of the garbage treated, this weight being about one-half that of the portion of the garbage reducible to fertilizer. The remaining three-fifths of the mixture is burned and produces electrical energy. The cost of a plant of twelve groups, each group with a capacity for 10 tons per hour, is estimated as follows:—

Land, 4.5 acres to be furnished by city, is not included:—

Buldings for the plant	$ 300,000
Offices and lodgings	60,000
The Mechanical Installations—	
Wagon-loading apparatus	$ 60,000
Sorting, crushing, etc., machinery	80,000
Producer system incinerators	220,000
Boilers	120,000
Electrical machinery	180,000
Expenses, loading, freight, etc., on construction materials and machinery	30,000
Paving about plant	50,000
Conduits and pipes for water and electricity	80,000
Side track	40,000
Miscellaneous	40,000
Contingencies	80,000
Total estimated cost of plant	$1,340,000

The cost of operation of this plant is not stated, but the amount of labor required is estimated at somewhat less than twice that required in an incinerator plant and about one-fifth that required for a reduction plant of about the same capacity.

The income from the plant using the mixed method is estimated as follows:—

The 400 tons of organic matter per day will produce 200 tons of fertilizer, or 73,000 tons per year. This is valued at $5 a ton, or $365,000 a year. The combustible waste is estimated to produce 50 k.w.-hr. of electricity per ton, and the 600 tons per day (219,000 tons per year) would produce 10,950,000 k.w.-hr. per year. Deducting 2,190,000 k.w.-hr. required about the plant leaves 8,760,000 k.w.-hr. for sale, which, at 2 cents, would produce $175,200. The total gross income from the plant for year would, therefore, be $530,200. In addition, there would be income from sale of rags, metals, etc., recovered.

These estimates may not fit American conditions exactly, but can be modified to fit them, and are certainly interesting. Even after deducting an expense of operation equal to that of running an incinerator plant with the addition of the greater labor cost in the mixed method plant at, say, $1 a ton incinerated, a handsome profit remains for the mixed method.

THE STRENGTH OF WIRE ROPES.

IT is frequently assumed that the stress causes in wires by bending them over pulleys is considerably lower when the wires are twisted in one or several strands than when single wires are tested. According to Bach, the former stress would be only three-eighths of the latter, and some authorities have based their regulations as to the strength of lift-ropes on the assumption of this coefficient. Bach was attacked in 1907 by Isaach-Sen, and the latter was supported by Bock, and last year by Wehage, who directed attention to the strains left in the ropes by the stranding. "Glück Auf," in a recent number, furnishes an interesting contribution to this question, though it is only based on preliminary experiments. Professor G. Benoit and Mr. Woernle are engaged on an investigation of the strength and durability of wire ropes, which they are conducting in the laboratory for hoisting-machinery of the Technical High School at Karlsruhe. This research will occupy them for some time to come; but as their experiments are pretty conclusive about the deleterious influences of twisting, they have published their preliminary results, which were reviewed lately in "Engineering," London.

The experiments in question were made with a patent cast-steel wire, 1 mm. in diameter, which they found had a strength of from 174 kg. to 180 kg. per sq. mm. (110 to 114 tons per sq. in.), the guaranteed strength being 160 kg. per sq. mm. The wire was tested as it was, and also twisted to a strand of seven wires, 3.1 mm. in diameter, there being six steel wires and a core of softer wire of a trength of about 86 kg. per sq. mm. This rope gave a strength of 805 kg.; the soft core was generally not broken in the test, because it stretched considerably. Three of these strands were then combined to a rope of 6.8 mm. in diameter, and five to a rope of 8.5 mm. in diameter; the latter cable was provided with a hemp core, the former not. The wires and ropes were applied to a pulley which was turned to and fro through an angle of about 90 deg. at the rate of 1,000 turns per hour; the bending and unbending of the wires thus took place always in the same direction; further experiments with alternating bending to different radii, etc., are now being made. A turn is understood to signify bending of the wire from the straight and back to the straight.

The size of wire under test was generally such that the stress amounted to 8 kg. per sq. mm. (5 tons per sq. in.). The pulleys were made of cast iron or zinc, and were used either in rough condition or filed or properly

turned true. Though sufficient oil was always supplied, and there seemed to be no damage directly due to friction, the good finish of the pulleys had a very marked beneficial influence on the life of the ropes. The single wires stood 198,710 bends; the twisted strand had one or two wires broken after 44,800 and 47,190 bends. The pulley diameter was 175.4 mm.

A slightly larger pulley, 180.4 mm. in diameter, was then taken. On this single wires stood from 122,000 to 200,000 bends; the twisted strand became injured in three wires after 40,860 bends; the cable of three ropes had one wire broken after 22,860 bends, and was practically done for after 36,440 bends; the five-rope wire began to fail after 35,000 bends, and was given up after 40,000 bends.

The twisted ropes thus proved to be much less safe than the untwisted wires, and it occurred to the investigators that the twisting might in itself be responsible for the loss of strength. The wires, ropes, and cables (except the cable with a hemp core) were therefore annealed. In the case of the wires and wire bundles the annealing was fully carried through; the strength of the wire was thereby reduced to 93 kg. per sq. mm. In the case of the twisted ropes the heating was only carried so far, that the cut rope did not show any tendency to uncoil. The wires stood 47,700 bends, the twisted wires 37,000 and 42,000 bends, when the rope was destroyed; the cable of three ropes failed after 15,400 bends, and was quite destroyed by 21,850 bends. In other tests the untwisted wires stood from 47,700 to 70,900 bends; in the simple rope wires began to break after 50,850 bends, and the experiments had to be abandoned after 70,020 bends. That the cable of three ropes proved weakest may be due to special accidental features as to the relative dimensions of the parts. But the experiments thus demonstrate that the twisting leaves considerable strains in wire ropes, and especially on those made of high-class steels, which are chiefly used in mine haulage and winding.

LAYING SIDEWALKS IN WASHINGTON.

One-half of the cost of laying sidewalks in Washington, D.C., is assessed against the abutting property, and ordinarily the commissioners do not order sidewalk construction until they have received a petition from the owners of more than one-half of the frontage along a block. An exception is made, however, where a walk becomes dangerous, the commissioners order the work done in such cases without waiting for a petition. The law requires them to advertise for two weeks their intention to lay sidewalks and curbs, and, after a hearing, to order the work done when, in their opinion, it is necessary for the public safety, health, comfort and convenience.

During the last fiscal year, $225,000, according to The Municipal Journal, was expended in paving sidewalks abutting private property, and $7,000 in placing sidewalks and curbs around government reservations. The sidewalks were constructed of cement by contract. The alleys were paved with asphalt block or vitrified block by day labor, 23,422 square yards of vitrified block and 18,214 square yards of asphalt block, both on a gravel base, having been laid last year. Cement sidewalks were laid by contract for the following prices: Large jobs adjoining paved streets, 90 cents per square yard; large jobs adjoining unpaved streets and all small jobs, $1.20 a square yard. Contracts have been let for next year's sidewalk work at 92¾ cents and $1.16¾, respectively.

PRODUCER GAS FROM WOOD.

Producer gas from wood was dealt with in a lecture recently delivered by G. E. Lygo before the Junior Institution of Engineers. It was only recently, he said, that gas plant makers had given serious attention to the subject of utilizing wood for use in gas producers. This was no doubt due to the higher price of a wood waste plant as compared with an anthracite plant and the low price of anthracite, but with the increased cost of coal, manufacturers having combustible waste materials of little value and difficult to dispose of were looking out for means of utilizing them, and the advent of reliable wood waste suction plants had given them an opportunity of effecting considerable economy. In these plants all kinds of wood, from sawdust to pieces 6 inches in diameter, cotton seeds, cocoanut shells, fiber, and dust, sugarcane, coffee husks, rice husks, spent tanning bark, rubber leaf waste, surface peat, etc., could be used.

Referring to the design of the plant, many points had to be taken into consideration which were not needed with an anthracite plant. The area of the generator was governed by the nature and size of the fuel, but, roughly speaking, it was 2½ times that required for coal fuel. The depth of the fuel depended upon its size and density. A deep fuel bed was necessary for large pieces of wood, else air passed through and ignited the gas in the top of the generator.

Small, dense fuel, such as sawdust and coffee husks, required a comparatively shallow bed, or its resistance would interfere with the working of the engine. The internal hopper must be designed to suit the fuel, some fuels falling evenly in the generator, while others formed a cone in the centre. The external hopper was of large capacity. A vaporizer was not required, as there was no necessity to keep down the temperature in the combustion zone, and the loss of hydrogen was more than made up by the volatile gases in the fuel.

The gas must be cooled and washed immediately it left the generator, else the heavy tar and dust in suspension would be deposited and choke the connecting piping. In Whitfield plants an anti-fluctuator was provided, which insured a steady flow of gas from the generator. The variation of pressure on the suction stroke rarely exceeded 1 inch of water, whereas 6 inches was not uncommon in plants without the anti-fluctuator.

The calorific value of wood when air-dried was approximately 6,000 B.t.u. per pound. The amount consumed per brake horse-power depended upon the moisture, which amounted to 10 to 20 per cent. in air-dried wood and 30 to 50 per cent. in fresh timber. Fuel which contained excess of moisture had to be dried until it did not exceed 60 per cent., otherwise it was difficult to make the generator fire burn evenly. The gas produced was of higher value than that from anthracite, namely, about 150 B.t.u. to 170 B.t.u. per cubic foot, as against 120 B.t.u. to 140 B.t.u. from the latter.

As regards cost of working, a test made with a Whitfield producer supplying an 84 brake-horse-power engine coupled to a 105 volts dynamo gave 540 B.t.u. for 2,072 pounds of fuel consumed, or 3.83 pounds of fuel per kilowatt. The test extended over 10 hours, and the fuel consisting of oak and elm sawdust and chips from working machinery, had no value for other purposes.

In one factory, before the installation of the producer, the same work had been done by a steam plant, when, in addition to the same amount of wood waste, upward of 500 tons of coal per annum were consumed.

CONTENTS OF THIS ISSUE.

ADOPTION OF LIQUID FUEL FOR MARINE WORK IN BRITISH COLUMBIA.

That oil for fuel is speedily replacing coal on British Columbia harbor craft is a fact that is daily becoming more noticeable. Practically all the Government vessels plying in and out of Canadian ports on the Pacific Coast are using oil burners, or will be using them in another six months. The Marine Department was the first to make the change, while now the tug boats, dredges, snag-scows, tenders, etc., operated by the Department of Public Works in Vancouver and Victoria harbors, and on the Fraser River, are experiencing a similar conversion.

It has been found that this is a change for greater efficiency, and particularly so in the operation of dredging machinery. A reduced pay roll is noticeable in the stoke-hold of the vessels that have adopted the new system, about half the number of firemen being required as when coal was the steam producer.

Of course, the adoption of oil has advanced its price. At the present time, merchants are maintaining but a slight difference in the matter of cost between oil and coal. Nevertheless, the marine yards at Esquimalt are doing a rushing business in the conversion into oil burners of a veritable fleet of dredges, tugs, and the like.

Among those vessels upon which the oil system has been found to give excellent service are the Mastodon, operating around Vancouver; The Fruhling, keeping down the sand banks on the Fraser, and the Lobnitz, engaged in rock excavating in Vancouver harbor. The New Westminster stern-wheel suction dredge, King Edward, and the dipper dredge, Ajax, of Victoria, are among the craft at present at Esquimalt undergoing the installation of the oil system of steam generation.

FEDERAL CITY PLANNING COMMISSION.

Ottawa, like Washington, seems destined to become a purely parliamentary centre. The House and the Senate have never been enthusiastic about making the city a great manufacturing or industrial point. Early this month the Ottawa citizens voted by a decisive majority against the continuance of the publicity bureau that had been organized to attract industries. The civic body seems to be in sympathy with the desire of Parliament to make Ottawa a real Capital—a Federal City—a place of dignity, impressiveness and majesty.

In this work the chief factor will be the Federal City Planning Commission, recently appointed and as yet without permanent staff. This Commission is said to be contemplating improvements for Ottawa and surrounding district that will likely total fifty million dollars. The work will be spread over a period of twenty or twenty-five years, in all probability. Federal buildings, parks, railroads, streets, boulevards and the general view from Capital Hill will be within the scope of the Commission's activities. A Capital of a half million population will be planned for—the Commission will not be near-sighted.

The work includes Hull as well as Ottawa—on account of the importance of Hull as the background for the Capital. The Rideau Canal and the Ottawa, Rideau and Gatineau Rivers are also included—with the possibility of the Rideau River being diverted—and of a huge joint power scheme being developed. Great changes will gradually be wrought in a territory about sixteen miles square.

And may we add the hope that when in 1934 the visitor to Ottawa has been duly impressed with the dignity and importance of Canada's Capital, that he will be able to obtain a drink of pure water—whether from the Gatineau Lakes or from a mechanical filtration plant.

FACTORY CONSTRUCTION IN REINFORCED CONCRETE.

There are two types of reinforced concrete factory construction—the one with outside bearing walls of concrete and few openings, the other, the skeleton type of construction, the walls being simply filling-in panels, built afterwards. It has been pointed out that the latter is the easier to build and the more economical, but that it calls for a consideration of the following points: The column and pilaster footings only need go down to a solid bearing, unless an excavated basement is required. Where there is a basement light walls reinforced horizontally from column to column, or vertically from the basement floor to the first floor, will retain the earth, the reactions being taken by the columns or by the basement and the first floor, while the walls may be reinforced to carry themselves from footing to footing, requiring no foundations of their own.

Where there is no basement the outside walls need only go far enough down to prevent frost working in under them, with possibly a shallow trench filled with cinders or gravel underneath. They can be reinforced to carry themselves from pier to pier and to support the walls above. By building the footings first, and carefully filling, settling, and levelling the earth and laying the floor on the ground, the shores to support the false work can be cut of even lengths, and there will be a good level surface to shore from. Columns and floors are built first, as in skeleton steel construction, and the outside panel walls are self-supporting, but not weight-bearing. They are built in between the pilasters entirely independently of the floors. They may be built at a later time, furnishing a convenient method of keeping the concrete gang busy while the concrete floors are setting or the wood forms are being shifted from floor to floor, or when the weather is too wet or too cold to permit of the laying of the more-important work of floor construction.

CANADIAN RAILWAY CONSTRUCTION IN 1913.

During the past year Canada's railway lines were extended by a total of over 3,000 miles of single track, not including some 450 miles of second tracking. Comparing this with 2,230 miles in 1912, 1,898 miles in 1911, 1,844 miles in 1910, 1,488 miles in 1909, and 1,250 miles in 1908, the mileage returns exhibit a rapid increase.

As will be noted by the table of statistics given on another page of this issue, the volume of construction work that has developed during the year greatly exceeds the figures of any previous year. There are over 3,000 miles in various stages of actual construction at the present time.

The Canadian Northern added over 1,275 miles to its trackage; 206 miles in British Columbia, 500 miles in Alberta, Saskatchewan and Manitoba, and about 580 miles in Quebec and Ontario. The Canadian Pacific laid nearly 600 miles and 200 miles on its Western and Eastern lines respectively. The Grand Trunk Pacific laid 480 miles in the West. The Transcontinental added 90 miles.

In addition to the above figures the Canadian Pacific built over 450 miles of second track, approximately two-thirds of which belongs to the main line west of Winnipeg.

Comparing Canada's 1913 railway building with other American countries, it is noticeable that the total single track construction of United States' railways during the same period of time is approximately equal to Canadian development, the difference being remarkably small. In 1912, the difference was approximately 750 miles. During both years, however, the United States railways have exceeded Canada's second track additions by about 900 miles.

The tempestuous conditions that have obtained in Mexico during the past year have made an enormous difference in the returns for construction activities in that country. During last year only 38 miles of line were completed as against 210 miles in 1912, and 350 miles in 1911.

LETTERS TO THE EDITOR.

Re the Proposed New Water Supply for Ottawa.

Sir,—It is a most extraordinary thing to find to-day in this country a plan to go to distant lakes at an expenditure of about $8,000,000 for the water supply of a city of the size and location of Ottawa, seriously recommended. Still more extraordinary is it to find it seriously considered.

There are to-day dozens of purification plants in this country and over the border in successful operation which, with some slight modifications to meet conditions of the Ottawa River water, would satisfactorily purify and render colorless the present Ottawa supply.

From the writer's experience with a 25,000,000-gallon filter plant, handling during part of each year the same water as obtains at Ottawa in the Ottawa River, he can say that $550,000 would erect and completely equip a 25,000,000-gallon filter plant of the highest efficiency at Ottawa which would give an absolutely satisfactory result using the Ottawa River water.

The above figure does not include the necessary connections with the city's present pumping plant as the cost of this would depend upon the relative location of the two plants.

But, as to the feasibility and absolute fitness of a modern so-called mechanical gravity filtration plant for the Ottawa water supply, there is not the least doubt.

Why throw away about $7,450,000 on the undertaking and then perhaps leave doubt as to the absolute safety of the supply?

F. H. PITCHER,
General Manager and Chief Engineer,
Montreal Water and Power Company.

Montreal, Jan. 6th, 1914.

On Expert Opinions of the Fixed Carbon Test.

Sir,—The writer has followed with considerable interest the series of articles appearing in your publication on the fixed carbon question and, with your permission, will supplement his original contribution with the following remarks:—

Three of your contributors advocate a fixed carbon requirement in some form or other; yet their different

views as to its application add more to the uncertainty of the subject than they accomplish as arguments for such a requirement.

Let us assume for the present that the test itself is a scientific determination which gives consistent results in the hands of skilled operators and that engineers are not interested in requirements which favor or discriminate against any special product or class of bituminous materials. With this hypothesis, let us review the statements of your fixed carbon advocates.

In your issue of November 13th, Mr. Pullar recommends that different fixed carbon limits be set for the various classes of asphalts in competition. This would, of course, be fair to all materials provided, of course, the engineer did not neglect any of the "classes" in his specification, but would it not be a step in a dangerous direction? Would not a manufacturer be justified in asking that different limits be set for other requirements such as ductility, susceptibility, etc., in order to suit the characteristics of his special product? At best this would involve complicated specifications likely to revert us to the practice of purchasing by "brand," the elimination of which is the very fundamental principle of the open scientific specification.

Furthermore, how would the method take care of mixtures of asphalts often used with much success, also fluxed materials. I have in mind the practice of some cities which base their requirements not on a crude or refined material but draw the specification for the finished asphalt cement ready for the paving mixture.

In Mr. Kirschbraun's discussion of December 4th, it is recommended that fixed carbon be limited by a purely arbitrary formula of which two essential factors are the fixed carbon and asphalt yield of the crude. As there is considerable variation in refining practice, how will the testing laboratory arrive at the yield of asphalt? Will they determine this by some laboratory test which may or may not represent manufacturing figures or will they look to the producer for this data? Without means of verification in either case, the inspecting chemist will be safer in basing judgment on the finished product alone.

Mr. Richardson, in the issue of December 18th, voices our indebtedness to Messrs. Pullar and Kirschbraun for their efforts in showing the direction of importance and interpretation of the fixed carbon requirement. How do these directions coincide with his recommendations as a result of so many years of experience? Both commentaries oppose any definite maximum limit but, to use his words "if the highest grade of material is desired to the exclusion of the cheaper residual pitches made from oils . . . . ," let us see what protection the city will secure by adopting Mr. Richardson's maximum limit of 15%.

In the sixth paragraph of Mr. Pullar's argument he mentions an asphalt showing 12.32 per cent. of fixed carbon which "was very poor and not suitable for bituminous work." Later on, in the twelfth paragraph we have, in striking contrast, the statement that "owing to peculiar characteristics of oils obtained from Mexico . . . a much higher fixed carbon is obtained . . . averaging between 14% and 18% for the well-known brands," and still further on we read that "Mexican oils will give satisfactory results despite comparatively high fixed carbon." I quite agree that the two gentlemen have done much to clear up the fixed carbon subject certainly in so far as a definite maximum limit is concerned.

The writer has not approached this subject in a commercial manner with the object of exploiting or condemning a brand or class of material, neither is he adverse to tests which show up inferiority but he has, independent of this discussion, found "fixed carbon" too empirical to be of any use as a refinery or inspecting test.

We may theorize as to "cracking," "over-heating" or other evidences of "improper refining," but if the test by which these defects are to be determined is a variable quantity then our structures of theory and argument become mere creations of sophistry. Take the fixed carbon reports of my sample No. 215, published in your issue of November 27th, 1913. From the variety of results submitted this sample could fall within several of Mr. Pullar's "classes"; would meet a like judgment by Mr. Kirschbraun's formula even knowing the fixed carbon and asphalt yield of the crude; also from the report of laboratory "B" it is within Mr. Richardson's flat limit of 15% though made from Mexican oil. Which of the six reports will one select?

To the writer it would seem that such chemical problems, which are at best uncertain, would be avoided by engineers until settled by the profession to which they more appropriately belong. If, however, the engineers wish a harmless excursion into the less familiar field, let them call for fixed carbon reports from several chemists on the same sample when, I feel sure, the absurdity of the situation will be realized.

LEROY M. LAW.

Baltimore, Md., Jan. 6, 1914.

A Reply to Prof. Richardson re "Fixed Carbon."

Sir,—I notice in your issue of December 18th an article by Mr. Clifford Richardson—who, as he states, has had many years' experience in the determination of the fixed carbon test and other characteristics of native bitumen for the Barber Asphalt Paving Company—as to the desirability of maintaining said fixed carbon determination in specifications drawn for the purchase of asphalt.

Mr. Richardson argues:—

"If an engineer, in the light of service tests, prefers material which has been well proved to be satisfactory, rather than residual pitch which has been a failure or is of an experimental nature, he will properly introduce into his specifications a provision that no bitumen would be acceptable under them which contains more than 15% of fixed carbon."

I am surprised that Mr. Richardson should at last acknowledge the real purpose of the fixed carbon test, and advise that an engineer should introduce that test in his specifications, in order that only the expensive natural asphalts—Trinidad and Bermudez—shall be used, when a franker method would be to specify these materials by name.

The fixed carbon test, except for the purpose of making a market for the so-called "natural asphalts" above stated, is now abandoned, and all up-to-date municipalities by abandoning the same are obtaining the advantage of competition, and are securing asphalt that has been proven better and cheaper than the impure natural asphalts, which were used in the early days of the paving industry, simply because there were no others. Much impartial expert testimony has proven that the fixed carbon test has no value in determining the quality of asphalt or its fitness for paving material.

EDWARD SLADE.

Montreal, January 5th, 1914.

RAILWAY TUNNELLING.

By **Leonard Goodday, C.E., M.E.,**
Late of the British Admiralty.

The following is not presented as being new to engineers, nor to contain formulæ or positive rules for constructing such works, as none can be laid down; no two tunnels ever being exactly alike in conditions affecting their construction. However, it is hoped that assistants to engineers and contractors will find the information of material practical value.

Tunnels should be sparingly used. They require great care and honest workmanship in construction, repairs being generally accompanied by great expense and delay to important traffic.

Light and Heavy Ground.—When a cutting attains 70 feet in depth it is generally advisable to tunnel. A cutting of this depth, for a double line of rails, with 27 feet width at formation, and 1½ to 1 slopes, contains about 1,027 cu. yd. of excavation per yard run. A tunnel in sound rock requiring no lining is a comparatively simple piece of work, but those in unsound ground, requiring a lining, are sometimes very difficult and troublesome, especially where the height to the surface of ground over the tunnel is small.

As a fact, the greater the distance between the surface and the top of the tunnel, the lighter will be the ground generally, and therefore the greater the ease of construction. The reason is that when near the surface, mining operations cause the whole of the intervening ground to be disturbed. Cracks appear on the surface, and the whole weight of the earth has to be borne on the timber and lining. This condition of things is called "heavy ground." When the tunnelling is at a considerable depth, the disturbance caused by mining is arrested before it comes to the surface, and the weight is borne in the ground itself, i.e., "keyed in," while the ground is then called "light." Ground of 50 feet or less is likely to be heavy unless the geological formation is a strong one. When operations are commenced the strata and direction of "dip" should be studied so that the probable pressure may be ascertained. Sinking shafts and driving headings will assist in this work.

"Clay backs" often exist between the faults in rock, the stone having been upheaved and broken in enormous wedges, the sides forming a zigzag line vertical to the line of the tunnel. Water, having run between the sides of these wedges, has deposited clay which readily becomes slippery. The first length may be driven through one of these wedges, with its apex downwards. Two, perhaps three, lengths may be got in, and no great weight encountered, where the wedge is pointing downwards. If the wedge points upwards a great weight is suddenly brought upon the timber, because the rock, having its base cut away, slides down between its clay sides, and an increased thickness of lining will be necessary.

Clay is not a desirable substance to tunnel through, however sound it may appear. Water and air have a great effect upon it. The former renders it unstable and dislodges it from behind the timber, causing the latter to give, while the air makes it swell, crushing and breaking the timber.

In heavy tunnelling a thick lining is required, which cannot be determined upon until the work has been partially opened out. In light tunnelling the same process must also be gone through, but in a modified form.

Sinking Working Shafts.—The line once determined, it does not follow that shafts should be permanent, but one may well be so if the tunnel is over 700 yards long and if there will be much traffic. This shaft will be useful for steam clearance and ventilation purposes. If an engine passing through leaves the tunnel full of steam, the engine driver of the next entering train is unable to see his signals. The number of shafts to be sunk is regulated by length of tunnel and time allowed for its completion. Two faces should be worked from each shaft, and a length for each mined and lined complete for, say, five yards in every 20 shifts or 10 working days and nights. One shift would work from each shaft and one work to the shaft from a "break-up." Allowing 600 working shifts per year and a full gang for every two faces, 30 lengths would be mined and lined per annum in each direction, 15 being worked from "break-up" faces.

Suppose a tunnel of one mile length has to be completed in one year, how many shafts should be sunk?

One should be sunk at each end of the tunnel, and mining carried on from it in one direction only. In the other direction a heading may be driven, for expediting the excavation of the cuttings leading up to the tunnel, if heavy. The possible work to be done in both directions is 300 yards per annum, and in 1½ years 450 yards, leaving 1,310 yards to be worked from, say, 3 intermediate shafts. With this number it may be completed in the specified time. Sinking these 5 shafts and driving the headings will take at least 6 months. A "break-up" should not be commenced in a heading until the headings are all through, and centre line accurately fixed. It will be seen from this that for a tunnel 1 mile in length with 5 shafts 2 years is not too long. Shafts should be nearly equidistant from each other and the lowest points should not always be chosen for a site; for, though of less depth to sink, surface water and pumpage will naturally drain into it. Water is one of the greatest obstacles encountered in tunnel works. Also, the "bank" or top of shafts require raising above the surface, to get tipping room for the excavated material. Temporary shafts should be at least 9 ft. square and of timber, and sunk vertically. The settings of timber should be sound, 10 by 10-in., halved into one another at the angles, and plugged through the halving. They should be 4 ft. apart, centre to centre, the first one placed about surface level. Poling boards 1½ or 2 in. thick will not be too strong for lining, and if thicker ones are necessary short ends of planks will serve efficiently. The first setting having been let in sufficiently to keep steady, the poling boards are set up around the outside and excavation carried out inside and from under the "setting," the boards being hammered down and following the excavation. Temporary props are kept under the angles to prevent settling. When 4 ft. has been excavated another setting can be placed vertically under the first, taking care that the lower ends of the first set of poling boards are behind the second setting, and so on. If the ground around and close to shaft is level, the pit mouth should be built up a few feet, this giving height for a tip for excavation. A "jack roll" may now be set up over this shaft with 2 small skips attached on opposite sides of the winding barrel, so that as one is ascending the empty one is descending. For raising the excavation and water this will serve very well for depth of, say, 40 ft., but a winding engine or horse gin will eventually be required for handling the material.

While the above is going on, arrangements must be made for erecting a "poppet head" over the pit's mouth,

and forming a gin ring with excavation already coming up. When a pit is over 25 yds. deep, a horse gin is too slow, and a winding engine is required. It should not be less than 14 h.p., and should be of the ordinary portable type—with its wheels removed and the engine resting on a solid bed. It should operate by belt, a friction winding gear, allowing continuous operation of the engine, and doing away with dangerous stopping and reversing. The skip descends by gravity and is regulated by a powerful foot-brake. A distinctive mark is often fastened to the steel wire rope to indicate, in passing over the pulley of the head gear, that the skip is at a certain distance from the bottom of the shaft; another mark near the other end of the rope indicating the skip's position when near the top. A bell should also be connected with top and bottom of shaft, and arranged to automatically ring when the skip is nearing top or bottom. When a skip is descending, the engine, although doing no work, should be kept running, and when a full skip is attached, and ready for lifting, the hanger-on at the bottom rings the bell, whereupon the brakesman simply throws the drum into gear with the engine. This does away with all jerking.

Suppose a lining is fixed at 2¼ ft. or 6 half brick courses, that the lengths proposed shall be 5 yards each, and that the bars necessary for supporting the ground while it is being mined and lined shall be 1½ ft. in diameter at the butt end. Suppose also that the weight upon the bars will cause them to sag or settle down 12 in. in depth before the arch is keyed (which is called the "drop"—the bar must be kept up to that extent to allow for such sagging) that the brickwork may be put in of full thickness under the sagged bar. It follows that the top side or "back" of bar must be 2½ ft. higher than the extrados, and that the under side or belly of the headtree of the top heading must be kept higher up and above this to allow for the bar being placed under it. Drive the top heading, and on arriving at the two open ends of the tunnel, the passage through it will be found at a higher level than the formation of cutting, and a consequent lift of some 15 feet for all material passing in or out of the tunnel. Next decide upon the position of the "break-up" between the shafts. A "break-up" is formed by opening out and lining a length midway between two shafts, after the heading is driven between them. This creates at once

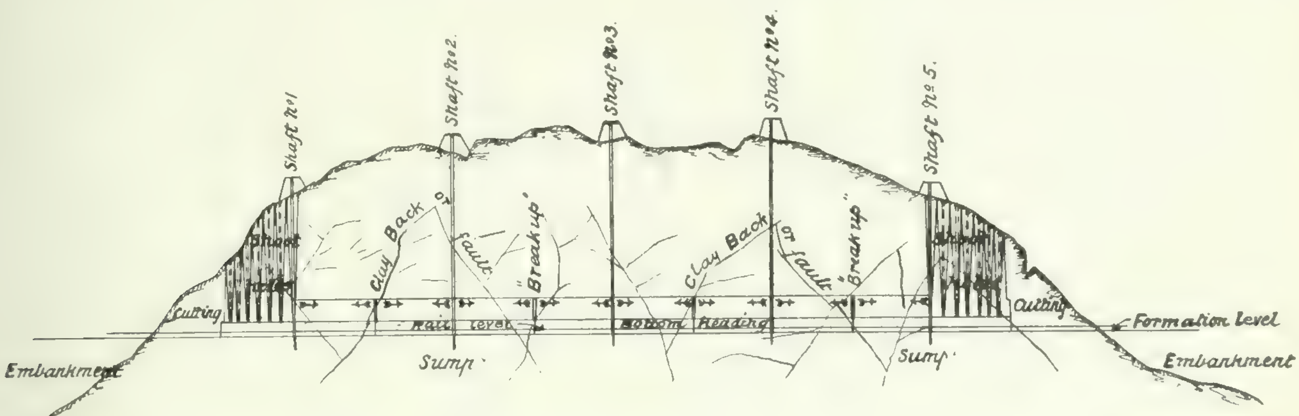

Fig. 1.—Longitudinal Section of a One-mile Tunnel.

Over the pit-mouth a bogie, or rolly, on 4 iron wheels about 12 or 15 in. in diameter and of a gauge equal to the full width of the shaft, should run on light rails laid back into a sort of dock sufficiently far to allow the rolly to be pushed back clear of the pit mouth. On the rolly are laid light rails at 2-ft. or 2-ft. 6-in. gauge on which are run small trollies. The full skip ascends clear of the mouth, the rolly with the trolly on it is pushed over the mouth and the skip then lowered upon the trolly. It is then disconnected from the winding rope and an empty skip attached. The rolly is then pushed back into the dock while the trolly and skip are run to the tip head.

At the bottom of the shaft a sump about 3 yds. deep is formed in the same way as the shaft, to collect water. A frame is built over it to form a cover to withstand stones, etc., which may fall down the shaft.

Headings.—A heading must be driven as a communication all through and between the working faces, and for accurately setting out a centre line below ground. Either a bottom heading at formation, or a top heading with its top a little higher than the extrados of the arch. A top heading must be made for each length, being necessary for lining in. It is necessary, also, for getting the "crownbar" into position. It is argued that, as the driving of this heading is most expensive in mining for the bars, why not drive right through at the outset. This is the only good argument in its favor as against a "bottom heading."

two new working faces, and facilitates the progress of mining and lining. It also permits more hands being employed, and the progress is thereby expedited. Each face is worked by a gang from each shaft. As the "break-up" is formed from a top heading whose bottom is about 15 feet above formation level all excavation below the bottom has to be raised into the heading and to the face working from the shaft; thence down that face to the shaft and up to the surface. Water must be dealt with in the same way until the faces from the shaft and "break-up" meet one another.

These are not the worst arguments against a top heading. Bearing in mind that a certain thickness of lining and that certain bars with a specified drop will be sufficient, the first length is commenced. Before about three are completed the calculations are found valueless, and that a lining 3 feet thick, bars 2 feet diameter with 18 in. drop are absolutely required to take the weight. Top of heading must be raised 1½ ft. or 2 ft. all through the tunnel despite the increased weight owing to the ground having been previously disturbed.

This raising in wet and heavy ground is exceedingly difficult, and will be found to cost fully 50% of the first cost of the heading. It may be claimed that the heading should be driven high enough at first. In this case if the first calculations are borne out this will entail all the more dry packing to be done between the brickwork and the roof of the mined ground. Again, in driving a top

heading at the outset, considerably stronger timber would be used, as some of it must remain under strain for approximately half the time during construction of tunnel; whereas, the timber used for supporting a top heading driven for each length as it is worked, would only remain understrain about 10 days, and consequently need not be so strong.

If "drawing bars" are used, they are placed under the head-trees of the top heading, the head-trees forming the top timber of the settings placed in this heading to support the ground, until the crown bar is in position and staved, remaining there until the brickwork of the length is keyed. The bars are then drawn, and serve for the next length. The head-trees cannot be extradicted and are lost (which supports the contention that this timber should be no stronger than necessary). In a light tunnel no "drawing bars" are needed, what are called "taking out bar" being used instead. In this case the head-trees can come out with them.

There is always considerable face weight in a length, i.e., pressure tending to shove the face forward into the length, and often causing a good deal of movement, more, of course, near the top than near the bottom of the length. This pressure dislocates the top heading timbers and the settings are found to slightly lean over toward the nearest working face. To keep them up, and the heading open, lining or intermediate settings placed between those originally set will be needed, and also lacing boards spiked from head-tree to head-tree, and from side-tree to side-tree. Even with these precautions a collapse due to this cause is not always averted.

Lastly, a bottom heading has the advantage of becoming a drain for all water above it, and so keeps the work in the top dry. It is better not to drive a top heading unless previously assured that there will be little weight, and that reasonable calculations as to lining bars can be depended upon.

Setting Outlines; Driving Headings, and Fixing Position of Working Faces.—As it is more desirable to drive a bottom heading, let it be supposed that all shafts are sunk to formation level, with a good sump under each with, for example, one shaft at each end and three intermediate shafts placed nearly equidistant.

The centre line must be accurately set out on the surface and permanent points fixed upon it, one on each side of each shaft and on the tangent, if there is a curve. They must be clear of all workings and not disturbed. It is well to suspend two copper wires from the top of either of the shafts, set up the transit over one of the points and sight along to the other across the shaft. Fix two pieces of wood on some convenient part of the headgear transversely, one on each side of shaft, and as far apart as the width of shaft will allow, so that the wires may hang freely from them. Cut a notch in each board in the centre line and suspend the wires in the notches with a 10-lb. plumb-bob. These bobs should swing in a pail of muddy water, or oil, care being taken that the wires are clear of timber, etc. Their line can be transferred to some fixed point on either side of the shaft, or by stretching a fine cord across them, which will be sufficiently accurate for driving 10 yds. of heading on either side. When this length is done more accurate lines are required. The wires are again swung and the transit taken down the shaft. Then, with a plumb-bob attached to a fine line, sight on to the line of the wires as nearly as possible with the eye. Indicate in some clay, put on the ground for the purpose, where this bob drops; set the transit over this mark and sight onto the nearest of the two wires. To provide sufficient light for this work, a hole should be pierced in one of the trunnions and a mirror and reflector placed in it, then, by holding a candle to the end of this trunnion and looking through the eye-piece, the hairs will be visible. If electric lights are used this operation will be facilitated. A convenient method of sighting the suspended wire is to have a piece of white paper held behind it, with a light behind the paper. Set the transit on this wire, then have the wire gently moved to one side and the cross hairs should cut the other wire. If not, then the point in the clay is a little out and the transit must be gently shifted until the wires coincide exactly with the cross hairs of the telescope. The centre line being now on the instrument, an iron staple may be driven into the head-tree of the heading, in the setting next but two to the face. In it file a nick exactly on the centre line, and repeat this on the other side of the shaft, without moving the instrument. By hanging plumb lines in these nicks an accurate line is obtained which will serve for another 20 yards or more each way.

Let every point be put in accurately, whether for permanent or temporary use. If a point is put in just for the time and not secure, it gets worked out of line, it causes no end of trouble and delays for rectification if a great error is produced. Too many "line points" cannot be used, provided they are all correct. Some get moved by pressure, shots, slips, etc. If there are plenty of points, suspend lines to all, and notice if they are in line. Take the line of the majority and immediately obliterate those in error.

Setting out a tunnel requires plenty of patience and perseverance in having everything correct.

If the tunnel is straight, and the heading fairly driven, it is easy to put in the working centre line by dropping a single wire down each shaft and ranging in the true centre already found.

Now set the transit at one shaft, and sight to the next; then reverse to that in the opposite direction. If the cross hairs do not cut on to both wires correctly, halve the error at both shafts, shift the instrument forward, and try the next shaft. Thus all five wires may be put into line. Now fix points in the heading between the wires at, say, every half chain, by driving a staple into the head-tree and filing a nick in it. Verify these points now and then by going over this process, as sometimes the mining operations cause the ground above to settle, shifting these points, and throwing the wires out of line.

The best way of giving lines on a curve is to drop one line down the shaft exactly in the centre, set the instrument in the line tangent to the curve, and let a second wire be dropped in this tangent line. Then, with the transit produce the tangent into the heading, placing points at every half chain, measuring the offsets to the curve from each point. Drive in staples and file nicks as before. Make a neat plan of this, setting out the points plainly, and give it to the foreman-miner, who should be a man of intelligence and able to use it. If a point is blown out by a shot, the foreman can help himself if he understands the plan.

Always set out centre lines with an instrument, for if carried out by rule of thumb, errors which, although not serious, are annoying, creep in, causing loss of time. Besides, if headings driven from opposite faces do not meet well, a "jink" is caused in the line of temporary

rails afterwards laid, and wagons will be continually running off at the jink. In a close heading the derailment of a full wagon is a great source of annoyance.

A bench mark having been established at the bottom of each shaft, by downward measurement, a "brob" should be driven into the timber at rail level and painted. If the tunnel is on a gradient a board about 15 ft. long, with one edge level and the other cut to the inclination of the gradient, should be fixed into position. The gauger can then level from the B.M. until sufficient heading is driven to allow of another B.M. being put in. The bottom of the heading should be kept about 1 ft. above the intended formation level. The size of heading, clear of all timber, should be enough to permit the free passage of a tip-wagon, for as soon as the headings are through, a line of rails will be carefully laid through the entire length of tunnel and connected with the cuttings at either end, and also with the outside works. This road will be commenced for bringing in heavy bars, timbers, bricks, mortar, etc., and for removing the excavated material.

A heading 7½ ft. high and 8½ ft. wide at the underside of the head-tree, and between the side-trees, will be sufficient. While sinking the shafts, etc., a good supply of small timber should be provided for this, averaging from 6 to 10 in. diameter, and also plenty of poling boards from 1 to 1½ in. thick, 6 to 9 in. wide, and about 4 ft. long. If the ground is loose and shaky, a great many such boards will be needed, and as the immediate supply of them direct from a lumber merchant is uncertain, and being without them is as bad as being without bricks and mortar, the lumber should be on hand. To ensure a constant supply for a 1-mile tunnel, at least two circular saw benches should be set up, and driven by the engines working the pits. A great many foot blocks, cleats and wedges will be needed, all of which can be cut by these saws. This sawing should not be done by piece-work; it causes much trouble in measuring the work done, and the miners will constantly come up the shaft for boards and wedges, which will not have yet been measured. The result is that the sawyer's word must be taken as to quantity, as it is impossible for the timekeeper or foreman to be always at hand.

The side-trees, when in position in the heading, should each have a 6-in. "sprag," i.e., they should lean inward to that extent. Hence, if the distance between them at the underside head-tree is 8½ ft. at the bottom of the heading, it should be 9½ ft.

Every side-tree in a heavy tunnel should be set upon a foot block of hard wood about 15 in. square and 3 or 4 in. thick, and placed about 6 in. below the proposed floor of the heading. This gives a wider bearing surface, and prevents the tree from sinking or cutting into the ground. Sometimes the floor of the heading will commence to rise or spring up, owing to the pressure above. If there are any signs of this, every second setting of side-trees, and sometimes every setting, should be placed upon a good square timber or sill, running across the heading from one side to the other, below temporary rail level. The weight on the side-trees keeps the ends of this timber in place, and the weight of the road and passing wagons keeps the middle from rising. Two side-trees and one head-tree, and a sill, when necessary, form a "setting." These settings should be placed at least at yard intervals, the poling board reaching from one head-tree to the other, and overlaping 3 or 4 inches. In soft ground these boards must be placed close together throughout.

[NOTE—Mr. Goodday's article will be continued in an early issue.—Editor.]

CALCIUM CARBONATE IN WATER.

AMONG the papers discussed at the annual meeting in London of the Institution of Water Engineers of Great Britain was one by William T. Burgess, F.I.C., on the solubility of carbonate of lime and its bearing on certain processes for the treatment of water supplies. The following constitutes the dominant features of his address:—

The majority of water engineers have to deal with more or less calcareous supplies, and there are two groups in particular who have to study the matter practically. On the one hand, many are in charge of works where the supplies are softened, the operation being mainly the removal of carbonate of lime, and, on the other hand, there is another group concerned in hardening their soft supplies, usually by the addition of carbonate of lime, with the object of neutralizing acidity and preventing possible action on lead.

The fact that carbonate of lime is such a common ingredient in hard waters was doubtless one of the reasons which made the late Dr. Clark select it as the representative substance in his well-known soap test, and to express degrees of hardness in terms of that carbonate.

Some of the best water-bearing formations are entirely, or largely, composed of carbonate of lime—e.g., chalk, oolite, limestone, etc.—but although waters derived from such areas are always hard from the presence of carbonate, the carbonate of lime itself is really a very insoluble substance in pure water. Many chemists have estimated the solubility, the results varying from 1 to 3 parts per 100,000 of pure water. Careful experiments by the author, using water as pure and free from carbonic acid as possible, have shown that 100,000 parts will only dissolve 1.5 parts of the carbonate.

Carbonic acid is the natural agent which accounts for the carbonate of lime in our water supplies, but it is incorrect to assume that the rain water which falls on calcareous areas carries sufficient carbonic acid to effect the solution. Rain water seldom contains more than 1 part of carbonic acid per 100,000, a proportion quite insignificant towards effecting the solution of such amounts as are found in chalk-derived waters. A much larger amount of carbonic acid comes from the decomposition and oxidation of the organic matters in the soil on which the rain falls, and the examination of water from a percolation gauge having a depth of only 3 ft. of soil-covered chalk has shown that such water may already contain half as much carbonate of lime as is found in water from many deep wells in the chalk. The carbonic acid holds the carbonate in solution as bicarbonate. Water saturated with carbonic acid at ordinary pressure and temperature will take up as much as 100 parts of carbonate per 100,000 of water, but nothing like this amount is ever found in public water supplies. From numerous analyses the author has made it appear that the proportion of carbonate of lime in calcareous waters is seldom over 30 parts per 100,000. (Carbonate of magnesia is much more soluble than carbonate of lime, both in pure water and in water saturated, or partly saturated, with carbonic acid.)

The elimination of the carbonic acid, which is loosely combined with the carbonate to form bicarbonate, will cause the separation of the carbonate of lime. Thus, boiling for some time drives the carbonic acid out of the water, and results in the deposition of the carbonate; the

water is softer after the operation, and on this account the hardness due to carbonate of lime is described as "temporary" to distinguish it from the "permanent" hardness caused by other soap-destroying ingredients which are not affected by boiling. Heat does not drive off the carbonic acid readily, and consequently the boiling process is neither economical nor efficient for softening water. It is not sufficient to heat the water to boiling-point; it must actually boil, and often five minutes' brisk boiling will only reduce the hardness due to carbonate of lime by about 50 per cent. In the ordinary domestic hot-water services to baths, the water rarely reaches boiling-point owing to the circulation, and but little of the carbonate of lime, such as is found in our London supplies, gets deposited in the boilers and pipes. The author has frequently tested the hottest water from bath taps, and seldom found the carbonate hardness reduced by more than one-eighth of the total. If the carbonic acid left the water easily on the application of heat, and thus caused a better separation of the carbonate, the users of calcareous waters would be obliged to have their hot-water boilers and pipes cleaned out at much shorter intervals of time than they do now.

After long storage calcareous waters tend to lose carbonic acid, particularly in open reservoirs where vegetation flourishes. In such cases the carbonic acid is utilized by the plants, and deposition of a certain amount of carbonate takes place, with corresponding reduction of the hardness of the water.

Most calcareous waters contain a little carbonic acid in excess of that in hypothetical combination as bicarbonate, and this excess can be partly removed by agitation with air; the removal of the excess causes a slight separation of the carbonate of lime. This is not a practical method of softening, but the author found that the carbonate hardness of a chalk well water was reduced from 23.5 to 10.4 parts per 100,000 in the course of some months by storage and occasional agitation with air. (Vegetation had no part in the reduction, as the water under experiment was kept in the dark.)

Many chemical substances may be added to water to combine with the carbonic acid, and thus reduce the precipitation of the carbonate; but of all these lime is the cheapest and best.

Removal of Carbonate of Lime from Water by Clark's Lime Process.—As is well known, the hard water is mixed with a proportion of lime water just sufficient to react with the carbonic acid which holds the carbonate of lime in solution; the carbonate originally present, together with that formed by the combination of the carbonic acid and lime, becomes insoluble, and falls out as a fine crystalline precipitate, leaving the water softened. This general statement requires a little qualification, for, as already explained, carbonate of lime has a slight degree of solubility in water entirely free from carbonic acid, the amount being 1.5 parts per 100,000. From this it follows that it is impossible to reduce the carbonate of lime hardness in the most favorable water below that figure—at any rate, by any simple lime process. (As an illustration of how close works practice may approach the theoretical limit, it is, perhaps, worth mentioning that the author has on many occasions found the carbonate hardness of softened water below 2 parts per 100,000.) The carbonate of lime is either allowed to settle down in large subsidence tanks, or, after giving a short time for the reaction, it is filtered off.

Considering, first of all, the method of subsidence in tanks, it is a matter of common observation that the time taken before the water clears is by no means constant. Sometimes the water is bright in six or seven hours, while at other times twelve to fourteen hours elapse before the precipitated carbonate has properly subsided. The reason for this variation, where the conditions are apparently identical, is obscure; but it probably depends on the way in which the lime water and hard water happen to mix, intimate mixture and good agitation favoring the formation of a fine precipitate. Although twelve to fourteen hours is usually sufficient for the subsidence and the production of brilliant water, there is a great advantage in allowing many hours more, for the water, although clear, is often in the condition of a super-saturated solution of carbonate of lime, and from such a solution the excess carbonate, while it does not form a further precipitate, will crystallize out slowly on the sides of the tanks, or, if sent out too soon, in the mains. One of the objects of this communication is to call attention to the fact that the full separation of the carbonate is often a matter which requires a much longer time than is usually supposed. The subject is best illustrated by the results of a few laboratory experiments. In the tests the waters were treated with the proper proportions of lime water to effect good softening, and after the precipitate had subsided, the perfectly clear top was carefully syphoned off at intervals and examined for total carbonate in solution.

A. **Chalk-derived Water.**—Total carbonate hardness in untreated water 22.5 parts per 100,000.

	Total carbonate found in clear water after softening.			
Time of subsidence ..	10 hrs.	25 hrs.	49 hrs	73 hrs.
Total carbonate in clear softened water in parts per 100,000	4.8	3.9	3.6	3.6

B. **Calcareous Water.**—Total carbonate hardness in untreated water 17.6 parts per 100,000.

	Total carbonate found in clear water after softening.			
Time of subsidence..	10 hrs.	22 hrs.	46 hrs.	70 hrs.
Total carbonate in clear softened water in parts per 100,000	3.1	2.8	2.4	2.1

C. **Chalk-derived Water.**—Total carbonate hardness in untreated water 22.4 parts per 100,000.

	Total carbonate found in clear water after softening.				
Time of subsidence..	12 hrs.	24 hrs.	36 hrs.	60 hrs.	84 hrs.
Total carbonate in clear softened water in parts per 100,000	3.7	3.3	3.2	3.0	3.0

A consideration of the above results is quite sufficient to show that even when perfectly clear water is drawn off and pumped to distribution there is more than a probability of the crystallization or separation of a small amount of carbonate of lime in the mains. The longer the time the water is stored before distribution the less the probability of deposit.

The author has made many experiments to ascertain the effect of partial softening in the delayed separation of the carbonate. In the tests recorded below the waters were treated with the correct proportion of lime water (A), and also with smaller proportions to effect less softening (B, C and D).

Calcareous Water.—Total carbonate hardness in untreated water 17.2 parts per 100,000.

Time of subsidence.	Total carbonate found in clear softened water, in parts per 100,000. A	B	C	D
10 hours	3.3	3.8	4.1	5.8
22 "	3.0	3.6	4.0	5.8
34 "	2.6	3.3	3.7	5.7
46 "	2.5	3.1	3.6	5.6
70 "	2.3	3.0	3.5	5.5
94 "	2.1	2.9	3.4	5.4
Total carbonate which separated out after the water had first cleared	1.2	0.9	0.7	0.4

Chalk-derived Water.—Total carbonate hardness in untreated water 20.1 parts per 100,000.

Time of subsidence.	Total carbonate found in clear softened water, in parts per 100,000. A	B	C	D
11 hours	3.4	4.2	5.8	7.2
23 "	3.2	4.0	5.6	7.2
47 "	3.1	3.8	5.4	7.1
71 "	2.2	3.7	5.4	7.1
Total carbonate which separated out after the water had first cleared	0.5	0.5	0.4	0.1

Only one conclusion can be drawn from the above figures, and that is that the more perfectly the water is softened the greater is the necessity for giving it a long period for subsidence, and it is the irony of fate that at works where the most efficient softening is aimed at the probability of deposition of carbonate in the mains is greater than at places where partial softening is the rule.

With regard to softening works where filtration is relied on for the removal of the carbonate, the question arises: Is such filtered water more or less liable to form an after deposition of carbonate than the clear water obtained from subsidence water? In the author's opinion the liability is certainly not greater.

At what may be termed filtration works the hard water and the lime water are intimately mixed in their proper proportions at once; this favors the formation of a very fine precipitate, a large portion of which remains suspended in the water during the short time, usually about one hour, until the turbid water reaches the filtering cloths, where the precipitate is arrested. The surfaces and pores of the cloths soon become coated with the fine crystalline precipitate, and in making its way through what is practically a porous surface of carbonate of lime crystals, the water tends to part with any excess carbonate which it really holds in solution. This action compensates for the shorter time taken in the filtration process, and thus places the clear products of the two systems nearly level with regard to their liability to form deposits in mains and pipes.

After all, it may be argued that at well-conducted works not much trouble arises from deposition in the mains, but the author desires to point out that it may be practically prevented by simple chemical means. The addition of a very small amount of acid to the treated water from either subsidence or filtration works will entirely prevent the after-separation of the carbonate, and carbonic acid is probably the cheapest and easiest applied. In this connection members may be reminded that in the rapid softening process of Archbutt and Deeley,* in order to prevent the after-separation of carbonates from the treated water, the water leaving the softening tanks is "carbonated" by the introduction of air charged with carbonic acid drawn from the chimney of a coke stove. The author has reasons for thinking that the application of such "carbonating" at ordinary softening works would often be useful to engineers. The introduction of a very small proportion of carbonic acid, even as little as 0.3 part per 100,000, is sufficient to check or stop the after-deposition of carbonate, and at places where smokeless, or nearly smokeless fuel is burned there is no reason why the ordinary flue gases, after washing, etc., should not be utilized. At subsidence works the possible output might be greatly increased, for with slight "carbonating" the water could be drawn off and pumped to distribution, or reservoirs, immediately after it had first cleared. In carrying out any experiments it would be necessary to proceed with caution, because the introduction of too much carbonic acid might lead to other troubles, but the author believes that the complete control of carbonating plant would not be difficult.

Introduction of Carbonate of Lime Into Water: Hardening.—The amount of carbonate that a soft moorland water is capable of taking into solution is strictly limited, and is governed by the degree of acidity, which can, of course, be determined by analysis. Moorland waters always contain some free carbonic acid, and often, in addition, other acid or acids. If the free acid is simply carbonic acid, any proportion less than 0.7 part per 100,000 will only affect the solution of 1.5 parts of carbonate of lime, the same proportion as pure water will take up. With greater amounts of carbonic acid the proportion capable of passing into solution is exactly that which corresponds to the possible formation of bicarbonate; thus a soft water containing 1 part of carbonic acid will dissolve 2.4 parts of carbonate of lime. When the water contains, in addition, another free acid, this will determine the solution of a certain amount of carbonate and liberate a corresponding quantity of carbonic acid, which can take up a further proportion in the form of bicarbonate. Knowing the amount of acidity in the water, the chemist can therefore calculate the maximum proportion of carbonate which is possible of solution.

The carbonate is usually applied to soft waters in the form of powdered chalk, or whitening, and if the question of cost could be neglected, theory suggests that the material should be in the finest possible state of division. The fine particles expose a great surface to the water, and have the advantage of remaining in suspension for a long time. This is not altogether a matter of theory, for the author's laboratory experiments with carbonate in various states of division show the advantage of using very fine particles.

The president was kind enough to furnish the author with samples of untreated and treated waters from the Wakefield Corporation works. Members who visited the works this year will remember that the water is treated with both carbonate of lime and lime water in order to harden it slightly. The author treated the raw water with a considerable excess of pure carbonate of lime for two days in a closed vessel, and afterwards estimated the amount which had passed into solution. The result was 3.4 parts of carbonate per 100,000, and this figure was exactly the proportion which was indicated as possible

*Journal of the Society of Chemical Industry for 1891, page 511.

from the analytical determinations of the original acidity of the water. The author found that combined carbonate and lime treatment employed at the works had increased the hardness by the equivalent of 2.5 parts per 100,000, and that the process had been so carefully adjusted that the product contained neither free lime nor free carbonic acid. The above notes show what can be done in the way of hardening by carbonate of lime, and indicate the limits of the process.

"Excess Lime" Method of Sterilizing Water.—In the Eighth Research Report to the Metropolitan Water Board, Dr. Houston gave an account of experiments demonstrating the sterilization of raw Thames water by treating it with lime considerably in excess of that necessary to effect softening alone. The treatment of soft waters was also dealt with, and in the Ninth Report (April, 1913), this matter is followed up and notes are given showing the practical sterilization of a "very soft, peaty river water" by small quantities of lime. Experiments are quoted showing that purposely polluted water could be brought to a reasonable standard of bacteriological purity by the germicidal action of 2 parts, or even 1 part, of lime per 100,000 of water, the former proportion being effective in forty-eight hours and the latter in 144 hours. With regard to the free lime left in the water, Dr. Houston states that, if thought desirable, it could be removed by the addition of bicarbonate of soda. Dr. Houston recognizes that there would be cheaper methods of neutralizing the excess of lime "although none perhaps so apparently free from any disadvantages."

The expense of the suggested treatment will be better understood when it is explained that any free lime left in solution will require to neutralize it exactly three times its weight of bicarbonate of soda, and as this substance costs about £6 a ton, or roughly six times as much as lime, it follows that the expense of neutralizing will be 18 times the cost of the free lime left in the water after sterilization. However, neglecting the question of cost, the method may be examined from the chemical point of view. The reaction which takes place is—

$$Ca(HO)_2 + 2NaHCO_3 = CaCO_3 + Na_2CO_3 + 2H_2O.$$

Hydrate of lime + Bicarbonate of soda = Carbonate of lime + Carbonate of soda + Water

The solubility of the carbonate of lime formed has an important practical bearing on the possibilities of the process, and the matter is best illustrated by giving the results of some experiments. Samples of pure water, free from carbonic acid, were treated respectively with lime in the proportions of 1, 2 and 3 parts per 100,000, and were afterwards "neutralized" with 3, 6 and 9 parts of bicarbonate of soda. In the case of the experiment with 1 part of lime + 3 parts of bicarbonate of soda no precipitation or separation of carbonate of lime occurred, even after keeping the samples three days; but in the other two cases the precipitate formed slowly, and then settled down in about twelve hours, leaving the water perfectly clear and brilliant; but these waters were left in the condition of supersaturated solutions, from which the carbonate slowly crystallized out on the sides of the containing vessels, and were thus in states favorable for making deposits in mains. Further, it was found that the waters which were originally treated with 2 and 3 parts of lime, and neutralized with bicarbonate of soda, deposited, in the secondary separation, larger amounts of carbonate than might have been expected after allowing for the known solubility in pure water. The experiments were repeated several times, but always with the same results, and further tests established the fact that carbonate of lime is really more insoluble in water containing a little carbonate of soda than it is in pure water. (Thus, in water containing 3 parts of carbonate of soda, carbonate of lime is only soluble to the extent of 0.27 part per 100,000, as against 1.5 parts per 100,000 in pure water.)

It is fairly evident that if the free lime to be neutralized by bicarbonate of soda in the "excess lime" process exceeded 1 part per 100,000, special precautions would have to be taken, otherwise considerable deposits of carbonate of lime might readily occur in the mains.

THE CONSTRUCTION OF A REINFORCED CONCRETE RESERVOIR.

THE accompanying illustrations and the following data respecting the design and construction of a reservoir and coagulation plant for the Anheuser-Busch Brewery at St. Louis, Mo., are from a paper to be read by Mr. Ed. Flad, M. Am. Soc. C.E., at the February 4th, 1914, meeting of the society. His paper includes a short explanation of the waterworks system of the company, the system having a capacity of over six million gallons per day, this water supply coming from the Mississippi River through two 20-in. cast iron intake pipes, being syphoned into intake wells, pumped into settling tanks, and clarified by chemical coagulant and rapid filtration before distribution. The chemical treatment was adopted in 1901, several years before the City of St. Louis itself began the treatment of water supply.

The low-service pumps of the system are in a brick pit, 30 ft. in diameter and 40 ft. deep. There are three centrifugal pumps having a combined capacity of 13,000,000 gal. per day, and one triplex, direct-acting pump having a capacity of 2,000,000 gal. per day.

There are two steel settling tanks, 75 ft. in diameter and 28 ft. high, one circular concrete reservoir approximately 150 ft. in diameter and 30 ft. deep, and one rectangular covered reservoir having a capacity of about 1,000,000 gal.

The filter plant comprises six Jewell filters, circular in plan, each 16 ft. in diameter, and three Reisert filters, recently completed, which are rectangular in plan, each being approximately 34 by 15 ft.

Chemical Treatment.—The water is settled by adding sulphate of aluminum (alum) and lime. A special three-story reinforced concrete building is provided for storing and preparing the chemicals.

The hopper for storing the lime is 36 by 9 by 14 ft. high, and has a capacity of 90 tons. It is placed in a pit so that it can be filled directly by shoveling from the cars. An electric elevator conveys to the third floor the hand-cars containing the lime or alum.

The alum is dissolved in a concrete tank, and is fed to the water by gravity. This alum tank has three rectangular divisions, each 10 by 7 by 5 ft. deep. Each division is charged with from 500 to 2,000 lb. of alum which is dissolved in water. It requires from 2 to 5 hours to dissolve one charge. The lime is slacked in iron tanks on the third floor. These tanks are rectangular, 12 by 12 by 7 ft. deep, with sloping bottoms. A false perforated bottom is provided at a depth of 30 in., on which the lime is placed and partly submerged in 1 ft. of water. After slaking, which requires about 1 hour, the attendant stirs the mixture, which passes readily through

the perforated bottom and into the lime tanks below. This milk of lime is stored in three vertical cylindrical iron tanks, 12 ft. in diameter and 18 ft. high, with conical bottoms. One charge of lime consists of from 2,000 to 6,000 lb., and the tank holds about 10,000 gal. of water, giving a 2½ to 7% solution. In these tanks the milk of lime is kept agitated by compressed air admitted at the bottom through a small perforated pipe.

The flow of both the alum and lime solutions is regulated by standardized orifices operating under fixed heads. The milk of lime is pumped into the supply pipe or settling tanks by a centrifugal pump. As a general rule, the lime is added to the water as it enters the first settling tank, and the alum as the water enters the second settling tank.

Consumption.—The maximum consumption of water during the summer is about 6,000,000 gal. per day, for which at times, 1,600 lb. of alum and 5,600 lb. of lime are required, or about 2 grains of alum and 7 grains of lime per gallon of water.

The water is used for boiler purposes, for condensing and cooling in connection with the ice machine, as well as for washing barrels, bottles, etc. It is not used in brewing beer, partly because of the natural prejudice against water taken from the river below the outlet of the large city sewers.

Reinforced Concrete Reservoir.—Reverting now to the reinforced concrete reservoir completed: After due consideration of the various possibilities as to the shape and location of the reservoir, a circular shape was decided on, and the diameter was made as large as the available space permitted. The elevation of the top was fixed by that of the water in the old settling tanks, which operate in series with the new reservoir; and the bottom was placed sufficiently low to pass below the fill of cinders and rubbish, and rest on the river silt.

Estimates were made of the comparative cost of a steel tank and a reinforced concrete reservoir. Exclusive of the foundations, pipes, gate-house, and accessories common to both designs, the steel tank was estimated to cost $32,000, and the reinforced concrete reservoir, $30,800. The reinforced concrete reservoir was supposed to have some advantage, being a more permanent form of construction and not requiring painting, and perhaps a desire to follow the latest fashion had a minor influence; at all events it was decided to use reinforced concrete.

The reservoir has vertical sides and is 153 ft. 6 in. in diameter at the top and 35 ft. deep at the centre. The side-wall extends 25 ft. 6 in. above the ground. The capacity is approximately 4,250,000 gal. There is a central partition, consisting of a 4-in. reinforced concrete wall, with buttresses, which starts at one side of the reservoir and passes diametrically across to within 14 ft. of the other side. The object of this partition is to make the entering water circulate around the reservoir before reaching the outlet. The diameter of the intake and outlet pipes is 30 in., and that of the waste pipe 24 in. The outlet pipe has a float and a hinged joint, so that water is always taken from near the surface. The valves controlling the flow are in a gate-chamber outside the reservoir.

Foundation.—The foundation is a 12-in. layer of concrete resting directly on the river silt and reinforced, in two directions at right angles, with 1 in. square bars, 2 ft. from centre to centre, making ½% reinforcement each way.

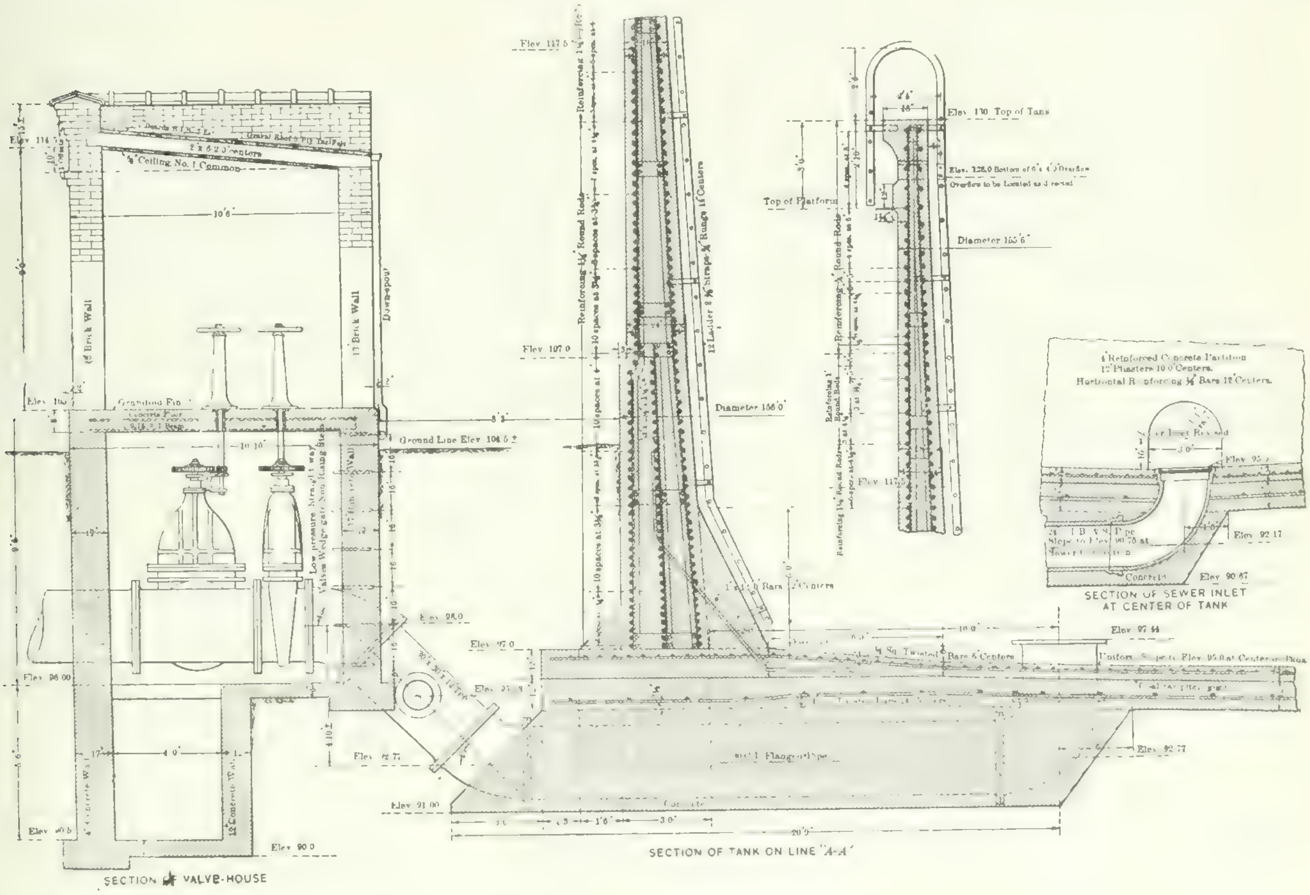

Fig. 1.—Section Details of Settling Tank.

On top of this foundation rests the bottom of the reservoir, which is 6 in. thick and reinforced in a manner similar to the foundation, except that the bars are ½ in. square and 6 in. from centre to centre.

The top of the foundation was coated with a thin layer of coal-tar, the object being to provide for expansion and contraction of the bottom independent of the foundation.

Side-Walls.—The thickness of the concrete side-walls is 7 ft. 6 in. at the base, 2 ft. 5 in. at the ground line, and 12 in. at the top. The pressure of the water is carried by hoop tension, the side-walls being reinforced circumferentially with corrugated round bars, under the assumption that the concrete carries no tension. There are three lines of 1¼-in. round bars at the bottom and two lines of ¾-in. round bars at the top, the sections and spacing being varied from bottom to top to correspond with the pressure. It was intended to allow a stress of 15,000 lb. per sq. in. on the bars. Owing to an error in the calculation, which, happily, was on the safe side, an excess of steel was used, making the stress per square inch somewhat less than originally contemplated.

The thickness of the concrete wall was fixed at each point so that the concrete would not be stressed more than 290 lb. per sq. in., under the assumption that no vertical cracks would develop under this tension. Assuming the modulus of elasticity of steel at 30,000,000 and concrete at 3,000,000, the actual maximum stress, if no vertical cracks develop, will be 2,900 lb. per sq. in. of steel and 290 lb. sq. in. of concrete.

The following formulas were used in determining the dimensions and spacing of the steel bars and the thickness of the concrete:

A = Area of bars, in square inches per foot of height of wall;

D = Vertical distance, in inches, between two layers of bars at the point selected;

T = Thickness of concrete wall, in inches, at the point selected;

p = Water pressure, in pounds per square foot, at the point selected;

r = Radius of reservoir, in feet;

s = Stress in steel, in pounds per square inch, allowed, under the assumption that the concrete carries no tension;

c = Stress in concrete, in pounds per square inch, allowed;

a = Area, in square inches, of steel in each layer.

The area of the bars required per foot of height of wall is

$$A = \frac{p\,r}{s}$$

The vertical distance between the layers of bars is

$$D = \frac{12\,a}{A}$$

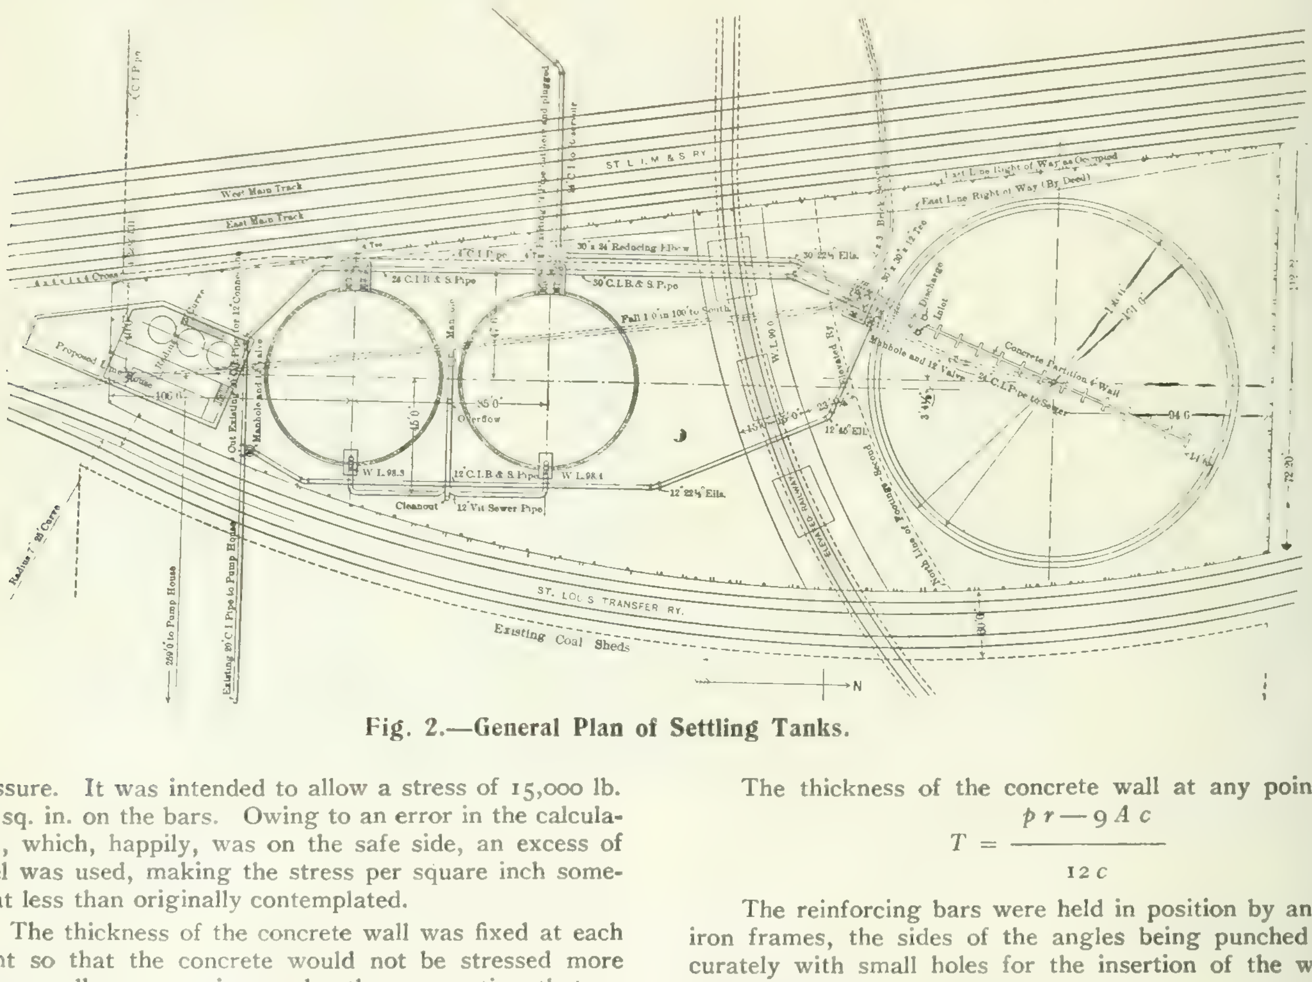

Fig. 2.—General Plan of Settling Tanks.

The thickness of the concrete wall at any point is

$$T = \frac{p\,r - 9\,A\,c}{12\,c}$$

The reinforcing bars were held in position by angle-iron frames, the sides of the angles being punched accurately with small holes for the insertion of the wires which tied the bars to the frame.

Splices.—The circumferential bars were in lengths of from 50 to 55 ft., and were spliced by lapping forty diameters and attaching two Crosby clips at each lap. The strength of this joint was tested by making up sample joints and pulling the bars in a testing machine. Two tests were made on each diameter of bar used, one with bars and clips without any mortar, and the other with the same joint embedded in cement mortar of the same mixture as that used for the walls of the reservoir.

The tests showed that the presence of the mortar did not add materially to the strength of the joint, as it failed either by slippage or by breaking off the clip. The first sign of slippage occurred at a stress of from 18,000 to

35,000 lb., and the ultimate strength of the joint varied from 25,000 to 75,00 lb.

Table I. gives the results of the tests.

Table I.—Tests of Bars.

Kind of bar.	Began slipping.	Broke at.
*1 ¼-in. round bar, plain......	....	75,600 lb.
† " " " with mortar	....	40,500 lb.
1 ⅛-in. round bar plain	37,400 lb.	....
" " " with mortar	32,200 lb.	32,200 lb.
1-in. round bar, plain	35,000 lb.	....
" " " with mortar..	25,600 lb.	25,600 lb.
¾-in. round bar, plain	27,300 lb.	30,000 lb.
" " " with mortar..	26,400 lb.	26,400 lb.

*1-in. slip at 18,000 lb.
†Mortar broke at 29,000 lb.

Forms.—The forms for the side-walls were built up of ⅞-in. tongued and grooved flooring, with 2 by 6-in. vertical studs about 2 ft. from centre to centre. The studs on the opposite sides were fastened together with iron wire passing through the forms. These wires were approximately 2 ft. apart horizontally and 4 ft. vertically.

The concrete was placed in the forms with a tower and dump cars running on a circular track.

Arrangements for Washing Out.—The bottom of the tank slopes toward the centre from all sides, the 24-in. waste outlet being at the centre. The slope toward the centre could not readily be made more than 2 in 75, being limited by the depth of the sewer which was already built. In order to facilitate the removal of sediment, therefore, the bottom was laid out in a series of star-shaped mounds, as indicated in Fig. 3, each mound draining into a shallow gutter. Hose connections furnish water under pressure for cleaning out.

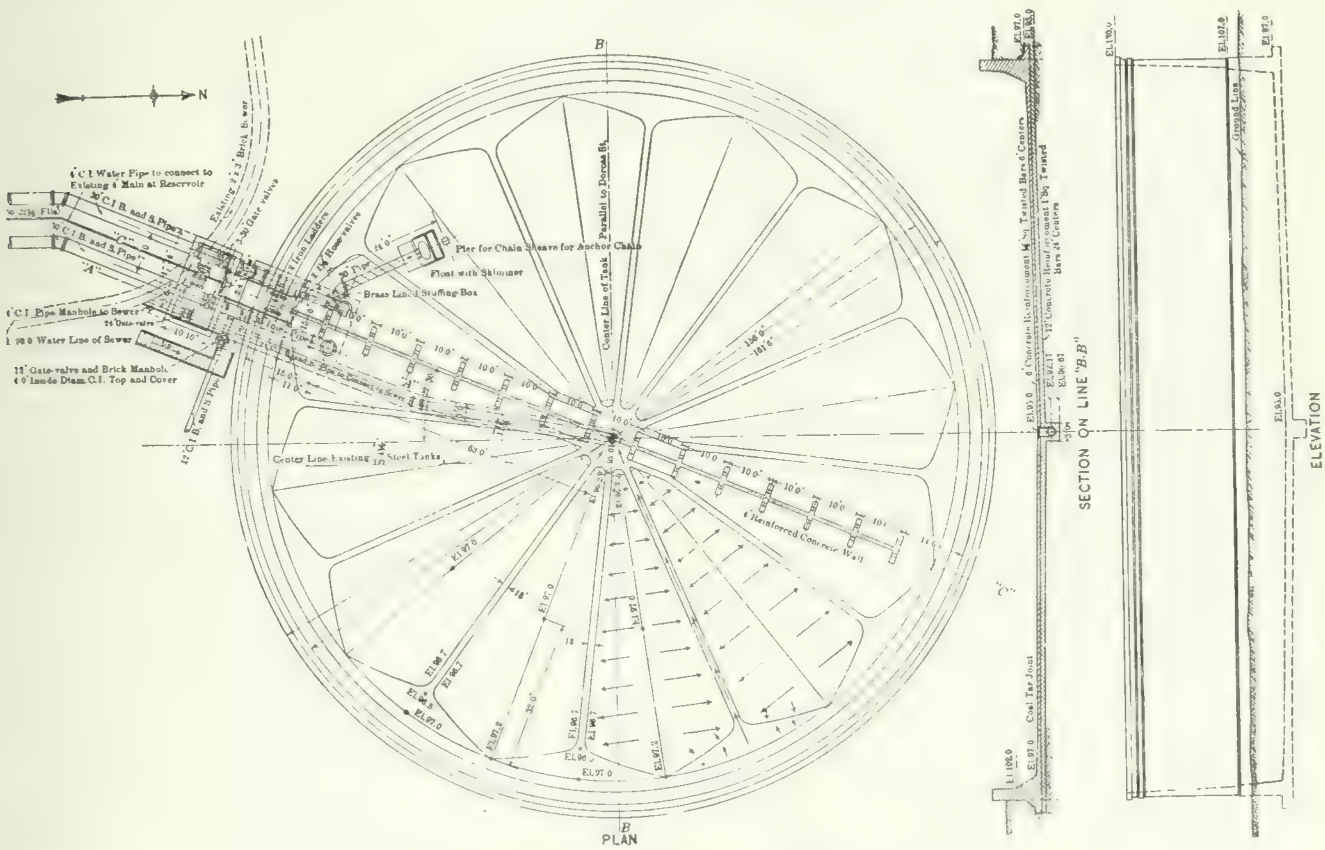

Fig. 3.—Foundation Plan of Settling Tank.

At the junction of the side-wall with the bottom, knee-bars are provided to reinforce this connection. These bars are 1 in. square and 12 in. from centre to centre.

Mixture.—The concrete in the walls and bottom is a mixture of 1 part cement, 1½ parts sand, and 3 parts limestone screenings run through a ¾-in. mesh screen, with the addition of 10½ lb. of Shamrock waterproofing to each barrel of cement. The composition of this water proofing is approximately as follows:—

Silica	60.0	per cent.
Alumina	15.0	" "
Lime	6.5	" "
Oxide of iron	1.5	" "
Combined water	10.0	" "
Gelatinous material	7.0	" "

This material cost 73½ cents per bbl. of cement.

Bond in Concrete.—Special precaution was taken to obtain a good bond between the successive layers of concrete. The old surfaces were scrubbed with brushes and a stream of water. In addition, 6-in. strips of corrugated plates, about 1/16 in. thick, were placed vertically in the joints. In spite of these precautions, when the reservoir was filled, small leaks developed along most of the joints, and efflorescence was quite extensive. These leaks appear to be closing up gradually, and it is probable that in the course of time they will disappear entirely. The intention, however, is to empty the reservoir and treat the joints with some waterproofing compound.

After completion the outside of the wall was rubbed with carborundum blocks and brushed with cement mortar.

The reservoir was designed by the writer's company, and was built under contract by the Fruin-Colnon Con-

tracting Company. The cost, including pipes and accessories, was approximately $52,000. The unit prices and total cost of the various classes of work were as follows:

Excavation, 7,801 cu. yd. at $0.80	$ 6,240.80
Plain concrete, Class A, 58.2 cu. yd. at $4.00	232.80
Plain concrete, Class B, 281.3 cu. yd. at $5.00	1,406.50
Reinforced concrete, 12-in. base, 759 cu. yd. at $5.00	3,795.00
Reinforced concrete, 6-in. bottom, 473.1 cu. yd. at $8.00	3,784.80
Reinforced concrete side-walls, 1,178.3 cu. yd. at $11.00	12,961.30
Reinforced concrete partition, 120 cu. yd. at $20	2,400.00
Reinforcing bars, 582,668 lb. at 1¾ cents	10,196.69
Clips for reinforcing bars	650.00
Ladders and angle-iron supports	852.16
Cast-iron pipes and valves	7,283.00
Gate-house	1,200.00
Miscellaneous	844.59
Total cost	$51,847.64

RAILWAY DEVELOPMENT IN 1913.

A FEW figures showing the extent of Canadian railway development during 1913, appear below. Those relating to single tracking do not take into account a vast amount of extension work that is in the preliminary stage, but refer entirely to lines upon which steel has been or is being laid.

Single Track.	Miles.
Algoma Central & Hudson Bay—In Ontario, one mi. north of Oba to Hearst	49.47
Algoma Eastern—In Ontario, from end of track to Little Current on Manitoulin Island	6.55
Campbellford, Lake Ontario & Western (Can. Pac.)—Glen Tay, Ontario, to Agincourt	182.30
Canadian Northern—British Columbia, 6.07 mi.; Alberta, 256.89 mi.; Saskatchewan, 166.82 mi.; Manitoba, 65.66 mi.; total	495.40
Canadian Northern Ontario (Can. Nor.)—Quebec, 8.00 mi.; Ontario, (between Ottawa and Port Arthur), 536.00 mi.; (between Sydenham and Ottawa,) 36.00 mi.; total	580.00
Canadian Northern Pacific (Can. Nor.)—British Columbia, Hope to Cisco, 62.00 mi.; Kamloops north to Cottonwood, 123.00 mi.; Westminster to Steveston, Lulu Island, 12.00 mi.; between Cisco and Kamloops, 9.00 mi.; total	206.00
Canadian Pacific—In Manitoba, Snowflake west 10.00 mi.; Virden branch between Virden and McAuley, 23.00 mi.; between Boissevain and Lauder, 28.80 mi.; in Saskatchewan, Estevan northwest, 54.5 mi.; Kerrobert northeast, 36.10 mi.; between Swift Current, Sask., and Bassano, Alta., 60.8 mi.; between Weyburn, Sask., and Stirling, Alta., 162.00 mi.; in Alberta, Suffield southwest, 32.3 mi.; between Gleichen and Shepard, 25.00 mi.; on Alberta Central branch, 40.20 mi.; Lacombe east, 12.00 mi.; in British Columbia, on Kootenay Central 63.5 mi.; on White-water-Kaslo line, 16.00 mi.; total	574.20
Esquimalt & Nanaimo (Can. Pac.)—McBride Junction to Little Jualienne river	8.50
Fredericton & Grand Lake Coal & Railway (Can. Pac.)—In New Brunswick, Mile 11 to Mile 23	12.00
Grand Trunk Pacific—In Saskatchewan, Cut Knife branch, 30.00 mi.; Biggar-Calgary branch, 67.00 mi.; Prince Albert branch, 8.00 mi.; Moose Jaw northwest branch, 52.00 mi.; Regina Boundary branch, 48.00 mi.; in Alberta, Tofield Calgary branch, 36.00 mi.; in British Columbia, west of Yellowhead, 122.00 mi.; and east of Prince Rupert, 117.00 mi.; total	480.00
Hudson Bay—Between The Pas, Man., and Port Nelson	100.00
Intercolonial—Georges river, N.S., to Sydney mines	8.80
Interprovincial & James Bay Ry. (Can. Pac.)—Lumsden's Mills, Que., north	10.00
Kettle Valley—In British Columbia	80.00
National Transcontinental Railway—In province of Quebec, 88.26 mi.; Manitoba, 2.22 mi.; total	90.48
Pacific Great Eastern—Between North Vancouver, B.C., and Dundrave, 4.50 mi.; between Newport, B.C., and Cheakamus, 13.50 mi.; total	18.00
Quebec Central—St. Sabine, Dorchester county, to St. Camille, Bellechase county	5.00
Reid Newfoundland Co.—In Newfoundland, Trepassey branch, Biscay Bay to Trepassey, 5.00 mi.; Carbonear to Bay-de-Verde, 53.00 mi.; Goobies to Black River, 15.00 mi.; extension Heart's Content branch to Heart's Content, 1.00 mi.; total	74.00
St. John & Quebec—Between Centerville, N.B., and Gagetown	90.00
Sydney & Louisburg—Waterford Lake, N.S., to Victoria Mines, 1.00 mi.; Morien Junction to Morien Village, 2.00 mi.; total	3.00
Temiskaming & Northern Ontario— Porquis Junction, Ont., to Iroquois Falls	7.25
Vancouver, Victoria & Eastern (Gt. Nor.)—Between Kilgard, B.C., and Sumas Landing	5.05
Total	3,086.00

The following figures give in detail the double tracking that was laid during 1913, or was nearing completion at the close of the year:

Canadian Pacific—Farnham, Que., to St. John's, 13.20 mi.; Agincourt, Ont., to Leaside Jct., 6.20 mi.; Islington, Ont., to Guelph Jct., 29.20 mi.; Azilda, Ont., to Cartier, 9.50 mi.; Hemegos, Ont., to Devon, 12.40 mi.; Ester, Ont., to Shumka, 32.90 mi.; Tarpon, Ont., to Mobert, 20.2 mi.; Navilus, Ont., to Port Arthur, 1.60 mi.; Semlin, Ont., to Paysiplate, 15 mi.; Gravel, Ont., to Dublin, 11 mi.; Bergen, Man., northeast, 20 mi.; Kemmay, Man., to Virden, 39 mi.; between Whitewood, Sask., and Grenfell, 8 mi.; Indian Head, Sask., to Regina, 42.00 mi.; Regina, Sask., to Pasqua, 34.80 mi.; Caron, Sask., to S. Current, 94.80 mi.; Ruby Creek, B.C., to Westminster Jct., 64.4 mi.; total	454.30
Toronto, Hamilton & Buffalo—Welland, Ont., to Fenwick	5.91
Vancouver, Victoria & Eastern—Ardley, B.C., to Still Creek	7.12
Total	467.33

A comparison of mileages of single tracking in Canada and the United States during the past 10 years is as follows:

Year.	Canada.	United States.
1904	316	3,832
1905	1,181	4,388
1906	1,007	5,623
1907	976	5,212
1908	1,249	3,214
1909	1,488	3,748
1910	1,844	4,122
1911	1,898	3,066
1912	2,232	2,997
1913	3,086	3,071

The Panama Railroad is now engaged in building a concrete sea wall along the front of the fill between the fire station at Cristobal and the end of the mole for the new piers, to be used by the buildings of the steamship companies. The total length of the wall will be about 350 ft. It is composed of concrete cubes, one yard on a side, which are laid in brick style and faced above the water line with a wall of concrete one foot thick.

COAST TO COAST.

Paris, Ont.—Hydro-Electric light was used in Paris for the first time on January 8th.

Nelson, B.C.—The plant of the Nelson Coke and Gas Company is being operated by the municipality.

Vegreville, Alta.—The main street of Vegreville is now illuminated by the town's recently discovered utility, natural gas.

Belleville, Ont.—The new branch of the C.P.R., known as the Campbellford, Lake Ontario, and Western Railway, which will connect Toronto and other Lake Ontario points with Belleville, will be opened for traffic shortly. The line runs between Agincourt and Glen Tay, a distance of 182 miles.

Montreal, Que.—The Intercolonial Railway of Canada has under way the following new construction: Nelson, N.B., to Derby Junction, diversion of line, 2.67 miles; St. Romuald, Quebec, to Chaudiere Junction, double tracking 3.75 miles; Pt. Tupper, N.S., to Sydney, N.S., grade revision, 91 miles; Oxford Junction, N.S., to Painsec, N.B., double track, 73.7 miles; Halifax Ocean terminals; passenger station at Sussex, N.B.; automatic blocks from Halifax, N.S., to Windsor Junction, 13.9 miles; from Moncton, N.B., to Painsec Junction, 7.2 miles; from St. John, N.B., to Hampton, N.B., 22 miles; and a line from North Sydney, N.S., to a point near Leitches Creek, 4.3 miles.

Vancouver, B.C.—Some indications that a regular service will be commenced next year on the P.G.E. railway north of Newport are an order recently placed by the company for 150 steel freight cars to be delivered at Newport during the months of March, April, and May next; the possible issue of an interim order by the provincial department of railways at an early date permitting the P.G.E. to operate trains over the completed portions of the line north of Newport in order to transport settlers going into the interior; the fact that steel rails sufficient to lay 30 miles of track are now being delivered at Newport, and that these are to be distributed along the new line early in the spring; and, finally, track has been laid 13 miles north of Newport and grading has been finished for a distance of more than 150 miles from the Pacific terminals, being well advanced beyond Lillooet.

Montreal, Que.—To guard against a subsidence of the soil, which might occur when the frost leaves the ground at any point where excavation has approached too closely to the base of the conduit, carloads of stone are being hauled to the place where the break occurred, which will be used to strengthen the aqueduct bank. A cribwork will be built along the conduit at a distance of a few feet; and after the crib has been filled with stone, earth will be used to fill in the space between the aqueduct and the crib. This work will form part of the programme for protection against water famine in case of emergency. The tapping of the Lachine Canal, the work for which is announced in the *Construction News* columns of this journal, is another phase of the same scheme.

Victoria, B.C.—Though about $2,000,000 of the sum of $9,682,600, appropriated last year by the Provincial Public Works Department, has not yet been spent, the amount of new construction which has been undertaken in public buildings, roads, bridges, wharves, etc., has exceeded greatly that of any previous year in the history of the Provincial Government. The mileage of new roads constructed amounts to over 700, and the mileage on which the department has been engaged, including the work done in repairs and improvements, amounts to over 12,000. Prominent among these roads is the Banff-Windermere highway, on which 16 miles of ungravelled roadbed have been constructed during the past season; and on the transprovincial road, at least 20 miles have been constructed through an abnormally difficult section. At Strathcona Park, under the supervision of Col. Thompson, Messrs. Casey & Lewis have cleared and grubbed 7.25 miles, which is now ready to grade, and have also built a permanent bridge. A large number of important bridges, from time to time noted in *The Canadian Engineer*, have been completed and a number are under construction at the present time. In view of the fact, however, that a large number of buildings cared for by last year's appropriations have not been completed, and also of the general relaxation in building activity, it is probable that the amount to be devoted to public works during the coming year will not approach the record sum expended last year.

Moose Jaw, Sask.—The total expenditure for the work carried out by the civic engineering department in 1913 was $378,059.13. Out of an estimated expenditure of $32,000 for the city engineer's office, when an expenditure of $18,761.26 was deducted for salaries and purchase, there was left a balance of $13,238.74. The total expenditure for the year on contracts covering the work on the high pressure dam, 11th Avenue subway, high pressure mains, sidewalks, curbs and gutters, Algoma Avenue sewer and water extensions, River Park bridge and abutments, was $212,86?.12. The only bridges constructed were those over the high pressure dam on Manitoba street east, and the park bridge over the Moose Jaw river. In the sewer and water extension branch of the department, the annual report shows that 2,139 houses in Moose Jaw are now connected with the mains and sewers. Also in the street cleaning department, an expenditure of $9,600 has sufficed to keep in excellent condition a certain area of paved streets; and the report advises that by increasing the area, the cost could be lowered proportionately. Finally, the water supply of the city, it is stated, is in better condition than ever before; and there is now no danger of shortage during the dry months. There is kept in the reservoirs a supply of 37,990,000 gallons, to which another 30,000,000 gallons can be added at will. Realizing that steps should be taken to increase the water supply to keep pace with the increasing population, the commissioners have investigated the possibility of utilizing the water in the Moose Jaw river and have obtained the consent of the government to proceed with the work. They recommend, therefore, in their report, that particulars as to cost be obtained.

Vancouver, B.C.—The park scheme for some time being planned by park board officials, under the guidance of Park Superintendent W. S. Rawlings and Engineer A. S. Wootten, embraces the development of the point of land in the old C.P.R. hotel site as a picnic ground, the laying out of the parks adjacent to the beach, and the building of a permanent bath-house. The park officials believe that the whole improvement could be completed for $150,000, an equal amount of this being expended each year for the next four years. The plan provides also for the construction of a pier, which would cost probably $75,000; but it is not proposed to build this until necessary. A rearrangement of the car tracks of the C.P.R. operated by the B.C. Electric Railway will have to be made; and several new streets will also be laid out and approaches will be boulevarded so as to form a chain from Stanley Park and English Bay across the proposed Burrard Street bridge and out to Point Grey. The seawall will be constructed of rock taken from the foreshore, to be used as a facing, and to be backed by concrete. Towards the north end, it will be about 4 feet in height, increasing to about 10 feet towards the west; and, at intervals, there will be shelters and steps down to the beach. It will provide for a 40-foot promenade of asphalt with ornamental lighting standards every 75 feet along the edge. The bath-house will be built on the pivotal point of the scheme, equidistant from each end of the promenade; and will harmonize with the

construction of the embankment. The seawall is expected to cost about $30,000 and the bath house an equal amount. Many changes and improvements are planned for the grounds surrounding the beach, chief among which is a fill of 2 to 4 ft. that will be necessary immediately east of the northern portion of the beach. Though the board will be forced to forego much of the work this year, it will commence the clearing up of the west end of the beach, now strewn with rocks, and the piling up of those rocks preparatory to building the seawall at that section. The filling of the other section of the park, now undeveloped, must be proceeded with before permanent improvements can be performed there; and for this work, the park board expects to get the sand to be dredged out of English Bay in connection with the harbor work in False Creek.

PERSONAL.

JAMES E. WILSON, superintendent of the sewer department for the city of Calgary, has recently tendered his resignation. Mr. Wilson is leaving the city's service to engage in private contracting.

E. A. CLEVELAND, of Cleveland & Cameron, Vancouver, B.C., gave an illustrated lecture on the Panama Canal to the Vancouver Branch of the Canadian Society of Civil Engineers at its meeting on January 7th.

C. E. CARTWRIGHT and C. M. ODELL addressed the Mining Section of the Canadian Society of Civil Engineers at its meeting in Montreal on the 8th instant. The former's paper was entitled, "The Outlook for Mining in British Columbia." Mr. Odell spoke on "Initial Proceedings in Opening Up a Coal Mine."

JOHN R. FREEMAN, consulting engineer of New York, is at present conducting an investigation into the condition of the Montreal water supply conduit, before and after its collapse, for a body of prominent citizens. According to a statement he will report upon the advisability of installing a high pressure water system independent of the present waterworks plant.

J. H. HOUGH, president of the Hughes Owens Company, Limited, of Montreal, has just returned home after an extended trip to Europe and the West Indies. Mr. Hough well deserved this vacation, his first in fifteen years, during which time he has built up his business from a one-room affair to the present large company, owning valuable buildings in Toronto and Montreal, with three other important branches.

C. R. MURDOCH, B.A.Sc., has discontinued his services as waterworks engineer for Edmonton, Alta. Since August last Mr. Murdoch has been designing a filtration plant for the city, and has recently completed his work. He also had charge of the repair of the waterworks intake, which is nearing completion. Through a change of policy the position of waterworks engineer is being discontinued, the department being placed directly under the control of the City Engineer.

T. C. FORD, B.S., Ch.E., A.M., formerly chief chemist for the American Asphaltum and Rubber Company, has joined Messrs. Pullar & Enzenroth, engineering chemists of Detroit, Mich., and the firm will be known in the future as the H. B. Pullar Company. Mr. Ford has been closely associated with Mr. Pullar for the past five years, Mr. Pullar having been assistant general manager of the American Asphaltum and Rubber Company until about a year ago. Mr. Ford is not only familiar with the testing of bituminous materials, but has had wide experience in the actual building of roads and pavements. He was one of the first four engineers to complete the special post-graduate course of highway engineering at Columbia University.

REGINALD W. BROCK, Director of the Geological Survey of Canada, has been appointed Deputy Minister of Mines, to succeed DR. A. P. LOW, resigned. Professor Brock has been director of the Survey for the past twelve years, during which time his ability has been well recognized by the geological and mining authorities of the Dominion and abroad. He was previously a professor at the School of Mines, Kingston. He received his technical education at Ottawa Collegiate Institute, Queen's University, the University of Toronto, and Heidelburg. He was born in Perth forty years ago.

TORONTO BRANCH—CANADIAN SOCIETY OF CIVIL ENGINEERS.

The annual meeting of the Toronto Branch of the Canadian Society of Civil Engineers will be held on Wednesday, January 21st, 1914, at 8 o'clock p.m., in the lecture room at the Engineers' Club, 94 King Street W. Election of officers for the coming year and the presentation of annual reports will be included in the proceedings of the meeting.

COMING MEETINGS.

AMERICAN SOCIETY OF ENGINEERING CONTRACTORS.—Annual Convention to be held in New York City, January 16th, 1914. Secretary, J. R. Wemlinger, 13 Park Row, New York City.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Annual meeting will be held in Montreal, Que., January 27-29, 1914. Secretary, Prof. C. H. McLeod, 176 Mansfield Street, Montreal, Que.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

NATIONAL CONFERENCE ON CONCRETE ROAD BUILDING.—Meeting will be held in Chicago, Ill., February 12th to 14th, 1914. Secretary, J. P. Beck, 72 W. Adams Street, Chicago, Ill.

AMERICAN SOCIETY OF HEATING AND VENTILATING ENGINEERS.—Annual Meeting to be held in New York, January 21st to 23rd, 1914. Secretary, E. A. Scott, 29 W. 39th Street, New York City.

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

CANADIAN SOCIETY OF CIVIL ENGINEERS

TWENTY-EIGHTH ANNUAL MEETING TO BE HELD AT MONTREAL NEXT TUESDAY, WEDNESDAY AND THURSDAY — M. J. BUTLER IS PRESIDENTIAL NOMINEE—REPORTS OF COMMITTEES—VISIT TO ST. LAWRENCE BRIDGE WORKS

FOR the first time in their new building on Mansfield Street, Montreal, The Canadian Society of Civil Engineers will hold their annual meeting next Tuesday, Wednesday and Thursday. Only a reception was held in the building—which was then only partially completed — during last year's annual meeting. Nineteen - fourteen, therefore, marks the beginning of a new era in the affairs of the Society, the members now formally inaugurating into their service the splendid new building of which the Society can properly be proud. The Engineers' Club of Montreal, at which there will be considerable entertainment for visiting members of the Society, have also greatly enlarged and handsomely remodelled their building during the past year, so the meetings this year will have the advantage of much greater facilities, both for work and pleasure, than have existed at any previous annual meeting.

Phelps Johnson

President of the Canadian Society of Civil Engineers in 1913; president of St. Lawrence and Dominion Bridge Co's.

M. J. Butler

President-elect of the Canadian Society of Civil Engineers for 1914; head of Armstrong, Whitworth of Canada, Ltd.

There will be five business meetings—at 10 a.m. and 3 p.m. Tuesday, at 3 p.m. Wednesday, and at 10 a.m. and 2.30 p.m. Thursday. The retiring president's address will be delivered Tuesday afternoon.

All visiting members will be guests of the Montreal members at a luncheon in the Windsor Hotel at 1 p.m. Tuesday. A complimentary smoking concert will be held at 8 p.m. Tuesday in the Society's building. The annual dinner will be served in The Engineers' Club at 8 p.m. Wednesday.

It is thought that there will most probably be a trip through the Mount Royal Tunnel, but the only excursion officially noted on the programme is to the works of the St. Lawrence Bridge Company, Limited, at Rockfield, near Montreal. The party will leave the Windsor Hotel at 10 o'clock sharp, Wednesday morning. By courtesy of the Montreal Tramways Company, special street cars will be provided to carry the party to and from the works. After the inspection of the works, the Bridge Company will entertain the visiting members at luncheon.

The president of the Bridge Company is the retiring president of the Society, Mr. Phelps Johnson. Mr. Johnson was born in the United States and practised as an engineer for bridge companies for some years before coming to Canada. From 1872 to 1879 he was engineer for the Hawkins Iron Works, at Springfield, Mass. In 1879 he became assistant engineer of the Wrought Iron Bridge Company, of Canton, Ohio.

In 1882 Mr. Johnson went to Toronto as engineer and manager of the Toronto Bridge Company, which afterwards became the Dominion Bridge Company. In 1888 he became chief engineer of the Dominion Bridge Company, at Lachine, P.Q., which position he retained until 1892, when he was appointed general manager of the company. He was elected president of the company at the last annual meeting, succeeding Mr. James Ross, deceased. Mr. Johnson had previously acted as

vice-president of the company. He is a member of the St. James Club, the Engineers' Club and the Royal St. Lawrence Yacht Club of Montreal. Mr. Johnson was vice-president of the Society in 1907 and was also a councillor for two terms of three years each. What is probably Mr. Johnson's most notable work was in connection with the design of the new Quebec Bridge, which will be an enduring monument to his ability as an engineer.

His successor as President of the Society will be Mr. M. J. Butler, of Montreal. Mr. Butler, like Mr. Johnson, will be elected by acclamation, as he was the sole choice of the nominating committee. Mr. Butler is well known as the former general manager of the Dominion Steel Corporation. Prior to that he was chairman of the board of management of the Canadian Government railways, and previously deputy-minister and

Prof. C. H. McLeod, Ma.E.
Secretary of the Canadian Society of Civil Engineers since 1891

chief engineer of the Department of Railways and Canals of the Federal Government. He is a member of several engineering societies and of a number of clubs, and has been engaged in some notable engineering projects in various parts of the Dominion. Mr. Butler is now the executive head of Armstrong, Whitworth of Canada, Limited. It was largely through the efforts of Mr. Butler and of Sir Percy Girouard, who is an honorary member of the Society, that there is now being erected at Longueuil, Que., a million-dollar Canadian branch of the well-known English steel-makers, Sir W. G. Armstrong, Whitworth Company, Limited. Mr. Butler was a vice-president of the Society in 1906 and 1907. He had previously been a councillor for two terms of two years each.

The nominees for vice-president are Mr. R. A. Ross, of Montreal, and Mr. A. F. Stewart, of Toronto. The retiring vice-president is Mr. J. G. Sullivan, of Winnipeg, who was a councillor in 1910 and a vice-president in 1911, 1912 and 1913. Mr. Sullivan is the well-known chief engineer of the Canadian Pacific Railway. Mr. H. H. Vaughan, of Montreal, and Mr. F. C. Gamble, of Victoria, will remain as vice-presidents during 1914, Mr. Vaughan having served two years and Mr. Gamble only one year of their three-year terms of office.

Mr. R. A. Ross was a councillor in 1903, 1906, 1907 and 1909. He is a consulting electrical engineer who has built up a national reputation, having been connected with a large amount of very important work.

Mr. A. F. Stewart was a councillor in 1911, 1912 and 1913. He is chief engineer of the Canadian Northern Ontario Railway and one of the chief men to whom credit is due for the success and rapid growth of the Mackenzie, Mann railway systems.

Either Mr. Ross or Mr. Stewart would, together with Messrs. Vaughan and Gamble, make a trio of excellent assistants to Mr. Butler in an effort to make 1914 a notable year in the history of the Society.

COMMITTEE REPORTS.

Among the committee reports which will be considered at the annual meeting, the report of the Committee on Reinforced Concrete is especially notable. The members of this committee are Mr. Walter J. Francis, chairman, and Messrs. S. Baulne, E. Brown, E. Brydone-Jack, J. Galbraith, P. Gillespie, H. M. MacKay, E. S. Mattice, C. N. Monsarrat, Michael Morssen, P. B. Motley and H. Rolph. They present a draft of standard general specifications for concrete and reinforced concrete as follows, certain subsequent modifications being noted at the end of the specifications:

MATERIALS.

1. CEMENT.

"Cement" shall be Portland cement complying in every particular with the "Specification for Portland Cement and Standard Methods of Testing" adopted by the Canadian Society of Civil Engineers.

As far as practicable the same brand shall be used throughout each piece of work.

2. SAND.

"Sand" shall be natural or artificial silicious material having particles graded from fine to coarse. It shall be free from dust, soft particles, vegetable loam or other foreign matter. The particles shall be of such a size that all will pass through a circular hole ⅛" in diameter in a thin plate and that none will pass through a circular hole 1-100" in diameter in a thin plate.

3. CRUSHED STONE.

"Crushed Stone" shall be silicious or calcareous material having fragments graded from fine to coarse. It shall be made by crushing natural rock or boulders having a crushing strength of at least 6,000 pounds per square inch, and be free from flat pieces, dust, soft particles and foreign matter. It shall be clean, hard and durable. The fragments shall be generally uniform in shape and of such a size as to pass through a circular hole 2½" in diameter in a thin plate and that none will pass through a circular hole ⅛" in diameter in a thin plate.

4. GRAVEL.

"Gravel" shall be the naturally produced material corresponding in every particular to the requirements of crushed stone.

5. CINDERS.

"Cinders" shall be hard, clean, vitreous clinker, thoroughly vitrified, crushed to such a size that all will pass through a circular hole 2½" in diameter in a thin plate and none will pass through a circular hole ⅛"

in diameter in a thin plate, and be free from sulphides, ashes, coal, coke or any material combustible at a temperature below 1,500° Fahrenheit.

6. WATER.

"Water" shall be fresh water and be free from oil, acid, alkalies or organic matter.

7. STEEL.

"Steel" shall have the properties set forth in Section 30, and be free from loose mill scale, excessive rust, oil or other foreign matter.

8. MORTAR.

"Mortar" shall be composed of cement, sand and water.

9. CONCRETE.

"Concrete" shall be composed of mortar and crushed stone or gravel, or of mortar and crushed stone and gravel.

10. CINDER CONCRETE.

"Cinder Concrete" shall be composed of mortar and cinders.

11. REINFORCED CONCRETE.

"Reinforced Concrete" shall be composed of concrete in which steel of small sectional area is systematically embedded at the time of depositing the concrete for the purpose of forming a composite structure in which the component parts act in unison in resisting applied forces.

12. REINFORCED CINDER CONCRETE.

"Reinforced Cinder Concrete" shall be composed of cinder concrete in which steel of small sectional area is systematically embedded at the time of depositing the cinder concrete for the purpose of forming a composite structure in which the component parts act in unison in resisting applied forces.

13. RUBBLE CONCRETE.

"Rubble Concrete" shall be the mass obtained by embedding boulders, fragments of rock, or both, in concrete while being deposited in place

METHODS OF CALCULATION

14. PROPORTIONING OF PARTS.

Every structure of concrete or of reinforced concrete shall be so designed that any possible combination of loading thereon will not produce stresses of greater intensity than the unit stresses given in this specification

15. LOADING GENERALLY.

The loads to be resisted shall be considered to consist of the dead load and the live load.

The dead load shall be the weight of the structure itself and any other fixed loads.

The live load shall be all loads other than dead loads.

The loads shall be reduced to their static equivalents by a recognized method of design. All dynamic, vibratory and impact effects shall be considered and provided for.

16. LOADS ON BUILDING COLUMNS.

In the case of columns in buildings which support three or more floors, reduction of live load may be made in accordance with this section, except in the case of buildings such as warehouses in which the floors are liable to be fully loaded simultaneously. For the columns supporting the roof and top floor the full live load shall be taken. For the succeeding columns taken in order, the full live load on such columns may be reduced successively by 5% until a reduction of 50% is reached. For all lower columns the live load shall be taken as at least 50% of that used in calculating the floors.

17. SPAN OF BEAMS AND SLABS.

The span of beams or slabs shall be the clear span plus the depth of beam or slab, but need not exceed the distance from centre to centre of supports. Brackets shall not be considered as affecting the clear span in this connection.

18. BENDING MOMENTS OF BEAMS AND SLABS.

Taking "w" to represent the equivalent static load per unit length of span of beam or slab, and "l" to represent the span length, the following bending moments shall be used,—

(1) For beams or slabs supported at both ends without constraint, $+\frac{wl}{8}$

(2) For beams or slabs continuous over three or more equal spans, $+\frac{wl^2}{12}$ at centres of interior spans and $-\frac{wl^2}{12}$ over their intermediate supports; and $+\frac{wl^2}{10}$ at the section of maximum bending moment in end spans and $-\frac{wl}{10}$ over their inner supports.

(3) For beams or slabs continuous over two equal spans only, $-\frac{wl}{8}$ over the centre support, and $+\frac{wl^2}{10}$ at the section of maximum bending moment in the spans.

When the spans are of unequal lengths, or when special cases of loading arise, the bending moments shall be computed on statical principles and due regard shall be paid to the influence of constraint at the supports in determining the maximum bending moments in the spans.

19. ASSUMPTIONS FOR STRESSES IN BEAMS AND SLABS.

The stresses in beams and slabs due to the bending moment shall be determined from the principles of the bending of homogeneous beams using the following assumptions,—

(a) that the modulus of elasticity of concrete in compression is constant,

(b) that the tensile resistance of concrete is negligible, and the steel reinforcement carries all the tension,

(c) that plane transverse sections of a beam before bending remain plane after bending,

(d) that the steel and concrete are properly bonded together, and that in beams reinforced on the compression side the two materials are stressed in compression in the ratio of their moduli of elasticity,

(e) that initial stress in the beam due to shrinkage of the concrete is negligible,

(f) that the depth of a beam is measured from the extreme compression layer to the centre line of the tension reinforcement.

20. PROPORTIONING OF TEE-BEAMS.

In beam and slab construction the design shall provide efficient bond between the slab and beam. The slab shall be regarded as forming part of the compression area of the beam. The effective width of slab so acting shall not exceed one-fourth of the span of the beam, and the overhang on either side of the stem of the beam shall not exceed four times the slab thickness, nor twice the width of stem of the beam.

Where a tee-beam is continuous, as at a column, and the bending moment undergoes reversal the stresses due to the end moment shall be computed as for a rectangular beam reinforced on both tension and compression sides. The compressive stress in the concrete may be 15% greater than the maximum specified in Section 27.

21. PROPORTIONING OF SLABS.

When the reinforcement of the slab runs in one direction only computations shall be made by the formulae for simple beams.

When employing slab systems where the reinforcement runs in two or more directions the designer shall use his judgment in the interpretation of theories regarding stresses therein, and of experimental results obtained from slabs so reinforced.

22. PROPORTIONING OF PIERS AND COLUMNS.

When the unsupported length of a compression member subjected to axial load does not exceed six times the least dimension of its effective area, it shall be deemed a pier, and if its unsupported length exceed the above limit it shall be deemed a column. All columns shall be reinforced.

The effective area of a column shall be the area included within the line circumscribing and touching the outermost reinforcing.

The diameter of a column shall be the least dimension of its effective area.

The length of a column shall be measured between its lateral supports, neglecting bracketing, and shall not exceed fifteen times its diameter.

UNIT STRESSES

23. ULTIMATE COMPRESSIVE STRENGTH OF CONCRETE.

In the absence of tests on concrete made from the materials to be used, the following values shall be taken as the ultimate compressive strength of concrete, twenty-eight days after mixing, having the proportions of ingredients as set forth.

[NOTE.—Reports to the annual meeting of other standing committees of the Canadian Society of Civil Engineers will be published in an early issue of *The Canadian Engineer*. EDITOR.]

Proportion of ingredients (cement, sand, crushed stone or gravel).......	Ultimate compressive strength in pounds per square inch				
	1:1:2	1:1½:3	1:2:4	1:2½:5	1:3:6
Kind of crushed stone or gravel............					
Granite, trap rock.......	3300	2800	2200	1800	1400
Gravel, hard limestone or hard sandstone.......	3000	2500	2000	1600	1300
Soft limestone or soft sandstone............	2200	1800	1500	1200	1000

24. Compressive Stress in Piers and Abutments.

The compressive stress in concrete piers and abutments shall not exceed 22.5% of the ultimate compressive strength of the concrete.

25. Bearing Stress on Piers and Abutments.

The bearing stress on piers and abutments shall not exceed one-third of the ultimate compressive strength of the concrete, if the compression be applied to a surface of concrete less than one-half the surface of the pier or abutment, otherwise the bearing stress shall not exceed 22.5% of the ultimate compressive strength of the concrete.

26. Compressive Stress in Columns.

The safe axial load on columns shall be determined by the following formulae,—

(1) Columns with longitudinal reinforcing only,

$$P = Af_c\,[1+(n-1)p]$$

(2) Hooped columns,

$$P = Af_c\,[1+(n-1)\,(2.4\,h+p)]$$

in which P = safe axial load, in pounds.

A = effective area of column, in square inches.

A_s = sectional area of longitudinal steel embedded in the concrete, in square inches.

$p = \frac{A_s}{A}$

f_c = 22.5% of the ultimate compressive strength of the concrete, in pounds per square inch.

n = modular ratio of steel to concrete = 15.

$h = \frac{\text{volume of circumferential reinforcing}}{\text{volume of column enclosed}}$

$\frac{P}{A}$ shall not exceed 45% of the ultimate compressive strength of the concrete.

For columns with longitudinal reinforcing only, p shall not be less than 0.01 nor more than 0.04.

Columns shall be deemed hooped columns when h is not less than 0.0075 nor more than 0.015, and when p is not less than 0.01. The value of (h+p) for hooped columns shall not exceed 0.05, and h shall not exceed p.

The length of a hooped column shall not exceed ten times its diameter as defined in Section 22.

27. Compressive Stress in Beams.

The compressive stress at the extreme layer of beams shall not exceed 30.0% of the ultimate compression strength of the concrete. The estimated compressive stress due to the end moment on a continuous beam may be allowed to exceed this value by 15%.

28. Shearing Stress in Beams.

The shearing stress, v, in the concrete of beams shall be computed by the following formula,—

$$v = \frac{V}{bjd}$$

in which V = total shear at any section, in pounds.

b = breadth of a rectangular beam, or of stem of tee-beam, in inches.

d = depth of beam, in inches.

jd = distance from tensile reinforcing to centre of compression, in inches.

For beams having tension reinforcing only, v shall not exceed 2% of the ultimate compressive strength of the concrete.

For beams in which part of the tension reinforcing is bent, as opportunity offers, so as to provide inclined shear reinforcing, the value of v shall not exceed 3% of the ultimate compressive strength of the concrete.

For beams in which v exceeds 3% of the ultimate compressive strength of the concrete additional shear reinforcing shall be provided in the form of stirrups inclined or normal to the tension reinforcing and looped around or connected to it. Using the above notation and letting s = spacing of stirrups, in inches, each stirrup shall be designed to withstand a pull of $\frac{2}{3}\,\frac{V_s}{jd}$ if set normally to the tension reinforcement, and a pull of seven-tenths of this amount if inclined at 45° to the tension reinforcing. The spacing of the stirrups shall not exceed the depth of the beam. Stirrups shall be of such a length that they approach within two inches of opposite faces of the beam, and they shall be so anchored or bonded that they can develop the pull for which they are designed. The value of v for beams so reinforced shall not exceed 6% of the ultimate compressive strength of the concrete.

29. Bond Stress.

The bond stress between concrete and steel shall not exceed 4% of the ultimate compressive strength of the concrete for plain or deformed bars, nor 2% of the ultimate compressive strength of the concrete for drawn wire.

30. Modular Ratio.

The ratio of the modulus of elasticity of steel to that of concrete shall be taken as 15.

31. Steel.

Steel for reinforcing shall have the following physical properties,—

	Medium Steel Bars		High Carbon Steel Bars		Cold-Twisted Bars from Medium Steel as specified
	Plain	Deformed	Plain	Deformed	
Ultimate Tensile Strength, in pounds per sq. inch = T.......	55,000 to 70,000	55,000 to 70,000	Minimum of 80,000	Minimum of 80,000	
Elastic Limit, Minimum, in pounds per sq. inch.	33,000	33,000	50,000	50,000	55,000
Elongation, Minimum, per cent. in 8 ins....	$\frac{1,400,000}{T}$	$\frac{1,250,000}{T}$	$\frac{1,200,000}{T}$	$\frac{1,000,000}{T}$	5%
Cold Bend Without Fracture (d = diameter, t = thickness)......					
For bars where d or t is less than ¾″	180° d=t	180° d=t	180° d=3t	180° d=4t	180° d=2t
For bars where d or t equals or is greater than ¾″	180° d=t	180° d=2t	90° d=3t	90° d=4t	180° d=3t

For each 1-8″ increase in diameter or thickness above ¾″ nominal diameter or thickness, and for each 1-16″ decrease in diameter or thickness for bars below 7-16″ nominal diameter or thickness a deduction of 1% shall be made from the above specified percentage of elongation; but these modifications for elongation shall not apply to cold twisted bars.

Material shall be free from injurious seams, flaws or cracks, and shall have a workmanlike finish.

Bars shall preferably be rolled from billets.

Cold twisted bars shall have at least one complete twist in a length equal to twelve times the thickness of the bar.

Re-rolled bars more than 1″ in diameter shall not be accepted.

32. Unit Stresses for Steel.

The following unit stresses for steel shall not be exceeded,—

In Tension,

Medium steel, 16,000 pounds per square inch

High carbon steel and cold-twisted bars, 20,000 pounds per square inch.

Re-rolled bars, 12,000 pounds per square inch.

In Compression,

All steel, 15 times the specified unit stress for the concrete in which it is embedded.

GENERAL REQUIREMENTS IN DESIGN

33. Limiting Proportions of Ingredients of Mortar Generally

Not more than three parts of sand shall be added to one part of cement

To make mortar, the exact proportions shall be determined before the commencement of the work, having in mind the strength and density required and the characteristics of the materials to be used.

34. Limiting Proportions of Ingredients of Concrete Generally.

To make concrete when using a mortar composed of one part of cement and one part of sand, not more than two parts of crushed stone or gravel shall be used; when using a mortar composed of one part of cement to one and one-half parts of sand, not more than three parts of crushed stone or gravel shall be used; when using a mortar composed of one part of cement to two parts of sand, not more than four parts of crushed stone or gravel shall be used; when using a mortar composed of one part of cement to two and one-half parts of sand not more than five parts of crushed stone or gravel shall be used; when using a mortar composed of one part of cement to three parts of sand, not more than six parts of crushed stone or gravel shall be used.

The exact proportions of the ingredients shall be determined before the commencement of the work, having in mind the strength and density required and the characteristics of the materials to be used.

35. Proportioning of Ingredients for Waterproof Concrete.

Where waterproofness is necessary the proportions of ingredients of the concrete shall be determined by experiment to obtain the requisite strength and the maximum density.

36. Limiting Proportions of Ingredients in Concrete for Beams etc.

In building construction one mixture shall be used throughout for girders, beams and slabs. In no case shall there be used a mortar containing more than two and one-half parts of sand to one part of cement, and to this mortar there shall be added not more than five parts of crushed stone or gravel.

37. Limiting Proportions of Ingredients in Concrete for Columns.

In building construction one mixture shall be used throughout for columns. In no case shall there be used a mortar containing more than two parts of sand to one part of cement, and to this mortar there shall be added not more than four parts of crushed stone or gravel.

38. Crushed Stone or Gravel for Fireproof Concrete.

Where fireproofness is necessary, crushed stone or gravel containing more than 5% of limestone shall not be used.

39. Fireproofing.

The steel reinforcing shall be protected by at least 3-4″ of concrete in floor slabs, by at least 1½″ of concrete in beams, and by at least 2″ of concrete in columns.

In concrete piers and abutments which may be subjected to the action of fire the outside concrete for a depth of 1½″ shall be considered as a protective covering and shall not be computed in determining the effective area of the pier or abutment.

40. Spacing of Steel.

The distance from centre to centre of adjacent bars shall not be less than the perimeter of the larger of the bars.

In slabs the distance from centre to centre of adjacent bars shall not exceed twice the depth of the slab.

41. Splicing of Steel.

As far as practicable all reinforcing bars shall be in one length. Welds shall be made, and the length of laps determined, so as to develop the full strength of the bar.

42. Minimum Lengths of Slab Reinforcing.

The ends of slab reinforcing shall completely cross the beam or girder on which the slab rests.

43. Reinforcing in Columns.

Vertical reinforcing bars shall be carried into the footings a sufficient distance to transmit the stress in the steel to the concrete of the footing by means of bearing and bond stresses. The bars of the lower sections of columns shall extend above the upper surface of the slab a sufficient distance to enable the bars of the next succeeding section of column to be effectively bonded with them.

Reinforcing bars over 1″ diameter may have their ends faced true and be butted with a sleeve not less than 12″ long.

The steel ties holding the vertical reinforcing in its assigned position shall not be more than 12″ apart.

44. Contraction Joints.

Contraction joints shall be provided unless sufficient steel is embedded to safely withstand temperature changes.

In mass concrete subjected to temperature changes construction joints shall be provided at abrupt changes of section, and preferably at sections not more than forty feet apart.

WORKMANSHIP

Mortar and Concrete

45. Foundations.

The foundations shall be trimmed as accurately as practicable and shall be at least as large as the dimensions on the approved drawings. Form work shall be erected wherever foreign material can become mixed with the concrete or mortar while the same is being deposited.

The bearing stratum shall be cleaned of all foreign material. It shall also be free from water if practicable. Under no circumstances shall mortar or concrete be deposited in running water.

46. Form Work.

Form work shall be substantially and accurately constructed. It shall be plumb and true to line, well fixed, braced and supported to carry the imposed loads, and be rigid enough to retain proper alignment and correct contours until the concrete will have become well set. Form work shall be sufficiently tight to prevent leakage. Immediately before depositing concrete the form shall be carefully cleaned out, after having been finally trued up. A coating of soft soap or oil may be applied to new forms. Such a coating shall be applied in every instance where form work is to be used more than once. Form work that has been previously used shall be thoroughly cleaned before re-erection and given a protecting coat of the same material as that already used on it. Form work shall be so fastened together that it may be removed without injury to any part of the permanent structure.

47. Storage of Cement.

Cement shall be stored in a weather-tight ventilated building. The floor of the building shall be raised above the ground to ensure dryness.

The cement shall be neatly piled in carload lots in the original sacks, and be marked in a distinctive manner for identification purposes.

48. Storage of Sand, Crushed Stone and Gravel.

All sand, crushed stone and gravel shall be piled on a site which has been cleaned free from vegetable and other foreign materials.

49. Measuring of Ingredients.

One sack of cement containing 87½ pounds net shall be taken as equivalent to one cubic foot of cement. All sand, crushed stone and gravel shall be measured by loose volume.

The necessary amount of water to produce the required consistency of mortar or concrete shall be determined from time to time taking into account the atmospheric conditions and the variations of moisture in the sand, crushed stone or gravel before mixing.

All of the materials shall be systematically measured throughout the whole of the work, and the required proportions shall be accurately maintained.

50. Mixing of Ingredients.

All mortar and concrete shall be made in batch mixers unless it is impracticable to do so, in which case it shall be mixed by hand.

Mixing by hand shall be done on a smooth water-tight platform. The sand and cement shall first be mixed dry until the whole mass is homogeneous and of perfectly even color throughout. Sufficient water

shall then be added to make flowing mortar. In the process of making the mortar the materials shall be turned over at least five times. If concrete is to be made the crushed stone or gravel shall then be added and the whole mass turned over at least four times and until it has become homogeneous and of even color and consistency.

Mixing by machine shall produce a homogeneous mass of concrete perfectly uniform in color and even in consistency, and the whole mass shall be in continuous motion within the machine for a period of not less than one minute.

The re-mixing or re-tempering of mortar or concrete which has partly set shall not be permitted.

The general consistency of the mortar or concrete shall be such that the mass will flow readily in the forms, and that it can be conveyed from the mixer to the forms without separation of the ingredients.

The temperature of the mixture on completion of the mixing shall not be less than 40° Fahrenheit. The crushed stone or gravel shall be heated artificially, if necessary, to obtain this result. In no case shall crystals of ice either in the sand or in the crushed stone be permitted to reach the mixing platform or the mixing machine.

51. Placing above Water.

The surface on which concrete is to be deposited shall be specially cleaned for the purpose. If the surface be rock it shall be given a coat of grout composed of equal parts of cement and sand well brushed into the surface and all the crevices. If the surface, vertical or otherwise, be of concrete which has set hard it shall be spalled or roughened and afterwards thoroughly brushed over with grout composed of equal parts of cement and sand. If the surface be of concrete which has not set hard the spalling or roughness may be omitted, but grout composed of equal parts of cement and sand shall be applied as specified above.

Mortar and concrete shall be placed immediately after being mixed.

Mortar or concrete which has partly set shall not be used.

Concrete shall be deposited in such a manner that the ingredients will not be separated, and the mass shall be consolidated by being worked after placing. The coarser ingredients shall be removed from contact with the formwork by the manipulation of a special tool.

The depositing of concrete at expansion joints shall be done with the same care and attention as that required to ensure a smooth finish to exposed surfaces.

In all cases laitance which may have formed on the surface of deposited concrete shall be carefully and entirely removed.

Concrete shall be deposited in approximately horizontal masses, and the work shall be stopped only at regular or temporary vertical bulkheads.

During freezing weather concrete shall be taken from the mixer and deposited in the forms so that no part of it shall be frozen and the temperature of the mass when deposited shall not be less than 35° Fahrenheit. The concrete shall be prevented from freezing until setting has taken place and until the process of hardening has begun.

Trowelled or floated horizontal surfaces shall be not less than one inch in thickness. They shall be composed of mortar or concrete proportioned according to the requirements for wear. The mortar shall contain at least one part of cement to two parts of sand. The concrete shall contain at least one part of cement to one part of sand and one part of finely crushed rock or gravel.

If possible the surfacing shall be applied immediately after the placing of the mass concrete, but when this is impracticable the mass concrete shall be thoroughly washed and treated with a coat of grout composed of equal parts of cement and sand thoroughly brushed in before the surfacing is applied. In trowelling or floating the surface pure cement shall not be used.

52. Curing.

Concrete shall be protected from the direct rays of the sun for at least three days after being deposited when the maximum temperature is above 60° Fahrenheit in the sun.

For a period of seven days after being deposited concrete shall be kept moistened when the maximum temperature in the shade is above 60° Fahrenheit.

53. Form Removal.

The forms shall not be removed from concrete work until the concrete is safely self-supporting, and, where additional concrete is to be added, until it has sufficient strength to safely sustain the superimposed load.

54. Placing Under Water.

When concrete is to be deposited under water the site shall be cleaned from all foreign matter and all currents of water shall be eliminated. The concrete shall be deposited immediately after mixing in such a way as to displace the water and at the same time to obviate the separation of the ingredients. The work shall be carried on in such a manner as to prevent the formation of laitance between successive masses of concrete.

Reinforced Concrete

55. General.

All the requirements of the preceding sections shall apply to reinforced concrete as far as consistent.

56. Crushed Stone and Gravel.

The largest fragments of crushed stone or pieces of gravel for reinforced concrete shall be of such a size as to pass through a circular hole ¾" in diameter in a thin plate.

57. Storage of Steel.

Steel shall be stored on skids clear of the ground and protected from rain and snow.

58. Fabrication and Placing of Steel Reinforcing.

All steel reinforcing shall be fabricated and placed in strict conformity with the dimensions on the approved drawings, and it shall be truly lined up and so held in position that displacement shall not occur during the depositing or manipulation of the concrete. All bars shall be free from bonds not specifically required by the approved drawings.

No material shall be permitted to adhere to the surface of the steel reinforcing until the concrete in which it is to be embedded is being deposited.

59. Cleaning of Form Work.

Immediately before depositing the concrete the form work shall be entirely cleaned of all foreign material, preferably by the use of a pressure hose and nozzle discharging water, steam or air.

In column forms an opening shall be provided at the bottom of the form work of every column in order that every particle of foreign material may be readily removed.

60. Depositing of Concrete.

The concrete shall be deposited in small quantities preferably as a uniform stream. It shall be manipulated in such a manner as to ensure perfect adhesion to the entire surface of the steel reinforcing and to remove all impounded water or air.

In depositing concrete in columns the work shall be discontinued at the elevation of the bottom of beams for a period of not less than three hours before depositing the beam concrete. In the absence of beams the elevation of the bottom of the slab shall be taken as the stopping plane. Before commencing the depositing of the beam concrete (or slab concrete in beamless systems), every column shall be examined for laitance, which if present shall be immediately removed.

The concrete for slabs shall be deposited continuously with the beams. Special care shall be exercised to procure perfect homogeneity of tee-beam construction.

61. Discontinuance of Work.

Every structural element shall be completed without discontinuance if practicable. Unless completed in one operation, beams and slabs shall be discontinued only by the use of vertical bulkheads placed at the section of maximum bending moment.

62. Freezing Weather.

In protecting reinforced concrete from frost a system which will drive the moisture out of the concrete shall not be used.

63. Form Removal.

The forms shall not be removed until the times named in the following table have elapsed after depositing concrete, not counting periods in which the temperature has been below 35° Fahrenheit.

Part	Minimum number of 24-hour days elapsed after depositing
Posts under beams and girders......	20
Floor slab panels..........	10
Wall forms...........	2
Column forms..............	4
Sides of beams and girders.........	4
All other parts................	10

Cinder Concrete

64. General.

All the requirements of the preceding sections shall apply to cinder concrete as far as consistent.

65. Storage of Cinders.

Cinders shall be stored on a site which has been cleaned free from vegetable and other foreign materials.

Reinforced Cinder Concrete

66. General.

All the requirements of the preceding sections shall apply to reinforced cinder concrete as far as consistent.

67. Size of Cinders.

The largest particles of cinders for reinforced cinder concrete shall pass through a circular hole ¾" in diameter in a thin plate, and none shall pass through a circular hole 1-8" in diameter in a thin plate.

Rubble Concrete

68. Soundness of Boulders and Rock.

All boulders and pieces of rock shall be perfectly sound, impervious and durable.

69. Embedding Rubble.

All boulders and pieces of rock shall be throughly cleaned of foreign material, and after being wetted they shall be either floated into the concrete matrix or placed upon a floating bed with full bearing, in which case the concrete, as it is being raised around them, shall be manipulated in a manner similar to that required for exposed faces of walls. The mortar in the concrete shall be made to adhere perfectly to every part of the surface of the boulders and rock.

TESTS AND INSPECTION

70. Tests of Materials.

All the materials shall be systematically tested in accordance with the recognized rules of the art for each material. The results of the tests shall comply with the requirements of these specifications.

71. Field Tests of Concrete.

Tests shall be made on concrete and mortar as the work progresses to check the density of the mixtures and the rate of setting. The test pieces shall be cubes, rectangular prisms or cylinders, having a volume of about one-fourth of a cubic foot. They shall be poured from the regular run of the mortar or concrete as deposited, and be left to set under the same conditions as the material in the structure. There shall be two such test pieces made from each day's work. The test pieces shall be carefully examined before the form work is removed.

72. Test Loads on Floors.

Test loads may be applied to a floor at any time after sixty days from the hardening of the concrete, but they shall not exceed one and one-half times the live load for which the floor has been designed. If no permanent deformations result from such loading the test shall be considered satisfactory.

73. Inspection.

There shall be constant competent inspection throughout the whole of the work

MODIFICATIONS AND CORRECTIONS BY COMMITTEE.

Section 7, first line, "Section 30" should read "Section 31."

Section 11, third line, Delete "composite."

Section 12, third line, Delete "composite."

Section 31, first line, Between "shall" and "have" add "preferably be made by the open hearth process and shall."

Section 31, second division, left hand column, Delete "Elastic Limit" and substitute "Yield Point."

Section 31, fourth division, Delete whole division and substitute the following:—

Cold Bend without Fracture, (t=thickness or diameter, d inside diameter of bend).					
For bars where t is less than ¾".	180° flat	180° flat	180° d=3t	180° d=4t	180° d=2t
For bars where t equals or is greater than ¾"	180° d=t	180° d=t	90° d=3t	90° d=4t	180° d=3t

Section 32, fourth line, Delete "20,000" and substitute "16,000."

Section 36, third line. Place period after "cement" and delete remainder of sentence.

Section 37, Delete first sentence and substitute "In building construction one mixture shall be used for the columns throughout the same story." Third line, Place period after "cement" and delete remainder of sentence.

Section 44, fifth line, Delete "forty" and substitute "thirty."

Section 46, seventh line, Between "A" and "coating" insert "thin, even."

Section 50, seventh and eighth lines. Delete "If concrete is to be made the" and substitute "If concrete is to be made, wetted."

Section 50, twelfth line, Delete "and" after "consistency."

Section 50, fourteenth line, Change period to comma after "minute" and add "and the entire batch shall be discharged before any further materials are placed in the machine."

Section 50, twenty-first line, Between "the" and "crushed" insert "water, sand and."

Section 50, twenty-second line, Delete "artificially."

Section 51, twelfth line, Between "be" and "deposited" insert "conveyed in water-tight carriers and be."

Section 51, after seventh paragraph insert two paragraphs as follows:—

"Arch rings shall be built in sections of such length as will permit of all concrete in any one section being placed without stopping. If circumstances render this impracticable, bulkheads shall be placed normal to the line of pressure.

"In building bench walls or abutments of arches, the tops of such walls shall be finished normal to the line of pressure, and no horizontal joints shall be made."

* * * *

REPORT OF THE COMMITTEE ON TRACK

Mr. C. H. McLeod,
Secretary, Canadian Society of Civil Engineers,
Montreal.

Dear Sir,—

Referring to your letter of May 15th, announcing the creation of a Committee on Track, composed of Messrs. F. P. Gutelius and A. C. MacKenzie and the writer, I beg to advise that, owing to a tremendous pressure of business, we were not able to hold a meeting until the 1st instant. This meeting was attended by Mr. MacKenzie and myself.

The subject assigned to the Committee is a very large and comprehensive one and the work to be carried on should be in accordance with a well defined programme, and, in order to conform to the wishes of the Council as to procedure, it seems to us that the Council should give a general outline of the subjects which should be first attacked.

This is the procedure generally followed in associations of this nature and is the one which we think will obtain the best results from the Committee.

The Committee is so small that we do not think we can carry on effective research work in a satisfactory manner, because in the work associated with track matters it is quite desirable that results obtained by the Committee should be after a very general study by the Committee, which should be representative not only as to individual railroads but locality. We are, therefore, impressed that there should be an increase in the membership of this Committee to at least eight or ten, and a Committee of this size can accomplish much more effective work.

We, therefore, recommend for consideration by the Council the following action:

1. That the Council shall instruct as to the general subjects it would desire given first attention, and we might suggest that two be selected from the following list:

Recommended specifications for tie plates.
Recommended specifications for angle bars.
Recommended specifications for various classes of tie treatment.
Recommended specifications for bolts, spikes, etc.
Recommended practice as to size of ties.
Recommended practice as to character of timber.
Recommended practice as to proper tie spacing.
Economics of Track Labor, embracing the following:

(a) Proper methods of conducting track work.
(b) Proper methods of measuring efficiency.
(c) Equating track values.
(d) Method of educating section foremen, and numerous other subjects could be suggested.

2. That the Committee membership be increased to ten.

We believe in the creation of this Committee the membership should not be entirely confined to railroad engineers, as there will be some features involved where it would be desirable to have the benefit of the views of men connected with steel manufacture, treatment of ties and other subjects which are associated with materials going into track use.

Respectfully submitted,

H. R. SAFFORD,
Chairman.

COMMITTEE

H. R. Safford, Chairman. A. C. MacKenzie.
F. P. Gutelius

MONTREAL, December 18th, 1913.

REPORT OF THE CANADIAN COMMITTEE OF THE INTERNATIONAL ELECTROTECHNICAL COMMISSION

The above Committee begs to report that during the first part of the year 1913 the Commission was very actively engaged in bringing to their final form the reports of the Special Committees on the Rating of Electrical Machinery, on Symbols, and on Nomenclature; in order that they might be presented at the then forthcoming Congress in Berlin, Germany.

This Congress was held as scheduled in the early part of September, and adopted to a large degree the above Reports, and also the recommendations of the National Laboratories of England, France, Germany, and the United States as to the characteristics of standard annealed copper. Through the courtesy of the Honourable W. B. Nantel, Minister of Inland Revenue, the Canadian Committee was able to send a representative in the person of the local Secretary, Mr. A. B. Lambe. A full report of the Meeting, which was attended by some seventy delegates, representing about twenty-four countries, will be issued shortly and will be obtainable on application to the Secretary of the Canadian Committee, but in the meantime, as evidence of the growing influence of the Commission, it might be mentioned that requests were received that the publications of the Commission be issued in German and Spanish as well as in English and French; further, that the Russian government, through the National Committee of that country, has extended an invitation for the 1917 Congress to be held in St. Petersburgh.

The General Secretary of the Commission, Mr. C. le Maistre, expects to pay Canada a visit early next year, on his way through to New York and San Francisco, in preparation for the next Congress, which is to be held in the latter city in 1915.

With the exception of Mr. J. J. Wright, of Toronto, who has resigned owing to business reasons, the membership and officers of the Canadian Committee remain as last year, namely—

L. A. Herdt, Chairman.	L. W. Gill.
O. Higman, Vice-Chairman.	J. Kynoch.
H. T. Barnes.	J. Murphy.
W. A. Duff.	T. R. Rosebrugh.

A. B. Lambe, Secretary-Treasurer.

L. A. HERDT,
Chairman.

OTTAWA, December 31st, 1913.

SEWAGE DISPOSAL COMMITTEE

820 New Birks Building,
4th June, 1913.

Prof. C. H. McLeod,
Secretary, Canadian Society Civil Engineers,
Mansfield Street, City.

Dear Sir,—

The Committee appointed by the Council, as set forth in your letter of the 14th of March last, to suggest names for the formation of a Committee on Sewage Disposal, and also to outline the duties of such a Committee, beg to report as follows:—

In view of the fact that a Committee on Sewage Disposal, of three years standing, has fully considered the subject and made a report thereon, which report was received at the last Annual Meeting of the Society, and also in view of the fact that since the date of your letter of instructions, a Committee has been appointed by the Council to represent the Society in co-operating with the Committee of the House of Commons in dealing with the same subject and in formulating legislation thereon, we are of the opinion that the appointment of any other committee is unnecessary until after the enactment of the proposed legislation.

Yours truly,
WILLIS CHIPMAN,
JOHN KENNEDY,
R. S. LEA.

SUPPLEMENTARY REPORT OF SEWAGE DISPOSAL COMMITTEE

On the invitation of Mr. George Bradbury, M.P., Chairman of the Committee of the House of Commons on the Pollution of Navigable Streams, Messrs. John Kennedy and R. S. Lea attended a Session of the Committee at the House of Commons, Ottawa, and gave evidence as to the problem in hand.

Professor C. H. McLeod, who was also present at the Committee meeting, testified as to the establishment of special courses in the universities on sanitation and allied problems.

R. S. LEA,
Chairman.

REPORT OF THE CONSERVATION COMMITTEE

In March last, the Chairman of the Committee on Conservation addressed a circular letter to the members of the Committee. Replies were received from a number of the members and are appended to this report.

Last year the Committee presented a report respecting Mr. Sauder's recommendation that the Society "urge strongly upon the Dominion Government the importance of making the necessary appropriations and providing the necessary staff to undertake in an intelligent manner the gauging of all streams of water supply and the location and survey of all sites suitable for reservoirs for the storage of water."

The Committee, in its report, enumerated briefly the requirements for adequate gauging of streams, the principal gauging operations that have been carried on in Canada, and its importance in connection with all water power developments. The collation and subsequent publication of all available data was strongly recommended.

On April 14 the Secretary wrote that Council were of the opinion that the Commission of Conservation should undertake the work of compiling and publishing the stream data above referred to. The pressure of other work did not, at the time, permit the staff of the Commission to undertake the work, but it is hoped that it will be commenced next spring and that all engineers will co-operate by supplying all available information.

The communication of Mr. R. O. Sweezey, Montreal, is as follows:—

"In so much as I am supposed to represent Northern Quebec on this Committee, I prefer to confine my suggestions for discussion to questions affecting that part of the country.

"WATER POWERS.—While I quite realize that the water powers of

Quebec are under Provincial control, I think that nevertheless the local government is open to receive recommendations from this body.

"Immediately north of the city of Quebec is an area of some 3,000 square miles set apart as a game reserve and known as the Laurentides National Park. This area lies between the waters of the Saguenay and St. Lawrence and comprises the headwaters of a number of important streams, including the Jacques-Cartier (drainage area 1,100 square miles), St. Anne de Beaupre (350 square miles), Batiscan and several others.

"In connection with the development of Seven Falls on the St. Anne River under a head of 430 feet, a minimum development of about 6,000 horse power is possible. The head waters of this river offer excellent opportunities for storage, which would increase the minimum available power to at least 12,000 horse power. But here the difficulty arises which seems diametrically opposed to ideas of conservation. The National Park authorities stubbornly resist any move to create storage within the Park, claiming damage to game by flooding areas and thus disturbing caribou, moose etc. It is hard to understand such arguments when it is a well known fact that the beavers, which are so plentiful in this park, do a great deal more damage by flooding than any possible engineering storage could do, yet no effort is made to remedy that evil. Moreover the important storage localities to be flooded are usually in deep valleys and burnt areas where the flooded areas are absolutely valueless. Considering that the city of Quebec is greatly retarded in its manufacturing growth by the lack of cheap power (steam power is now used for city lighting), and, further, in view of the fact that the tract of 3,000 square miles thus reserved is, apart from the timber rights, quite unproductive an area owing to its rough and mountainous nature, one of the least benefits that might be expected from it is the utilization of its natural value as a storage basin for augmenting its water powers.

"There seems to be a strong tendency, both in Dominion and Provincial forest park regulations, to forbid the establishing of artificial storage within park limits. I would like very much to hear any arguments which might be offered in defence of such a policy.

"Indians.—As a natural resource the Indians of Northern Quebec and Northern Ontario are important. They are fast dying off and no effort is being made to alleviate their sufferings or to provide means for their livelihood. In this connection I have recently written to the Rt. Hon. R. L. Borden. Copies of this correspondence are attached hereto.

"I should very much like to have a discussion of this subject by the members of this Committee."

Mr. W. H. Breithaupt, Berlin, Ont., has made a special study of flood conditions on the Grand River, Ont. He has promised a fuller report at a later date, but in the meantime has contributed the following:

WATER CONSERVATION

Control of the Grand River, Ontario

"In the way of preliminary investigation of the economic practicability of control of the flow of the Grand River, Ontario Peninsula, by means of storage, sufficient in volume to impound a large proportion of flood flow, and thus prevent excessive floods and give a well sustained flow in the low yield periods, the Hydro-Electric Power Commission has during the past month carried on, and is still continuing, a survey and various investigations throughout the river valley. A lineal survey from outlet to headwaters, establishing of bench marks with elevations and distances from outlet of the river, flow gaugings, and topographical delimitations of possible storage basins, have been the lines of work. Investigation of the basin in Pilkington township on the main river remains to be completed, and a satisfactory site for a sufficient reservoir on the Conestoga tributary, which empties into the main river a short distance below Pilkington township, remains to be found.

"The unfinished present stage of this work has prevented any conclusion being reached as yet. It is hoped that for a later report information that has long been wanted will be available.

"The various cities, towns and smaller communities in the drainage area of the river have made large growth during the past year. To many of them, flood diminution and sustained flow of the river are of vital importance. The spring flood this year was again very high, only slightly under the record flood of 1912, and did much damage along the entire course of the river.

"The rapidly growing manufacturing town of Galt on the river made an extended investigation during the past summer with a view to enabling passage of flood waters without local damage. The river channel is narrowed by encroaching buildings, and obstructed by piers of short span bridges and by small boulders and detritus on the bottom and along the sides. A plan for a smooth, well defined and unobstructed channel was prepared, but for various reasons no action has yet been taken."

Mr. A. E. Doucet, Quebec, writes as follows:

"I am sorry to say that I have not been able to devote very much time to look into possible suggestions for inclusion in the annual report of the Committee. As a railroad man, however, and familiar with the operation of railways through timber country, I am more than ever convinced that our generally accepted width of 100 feet for right of way is very much too limited. I know that this point has already been brought up before the Committee, but it seems to me that in future the right of way through bush lands should certainly not be less than 200 feet, and a law should be passed to this effect for all future construction work."

Mr. J. B. Challies, Ottawa, has contributed a very interesting memorandum respecting the proposed forest reserve in the basin of the Winnipeg River. He says:—

"In response to your request this morning for my views regarding the work of the Conservation Committee of the Canadian Society of Civil Engineers, I would submit the following:

"Engineers both in the Government Service and in private practice have for many years been seriously handicapped in their endeavour to secure quick and authentic information respecting the results of surveys, investigations etc. of the different departments of the Dominion Government and of the several Provincial Governments, by the lack of some central office to which enquiries could be addressed. The situation in the United States has been partially met by the creation of an office for the distribution of public documents issued by the various departments of the United States Government, and a monthly catalogue issued by the Superintendent of Documents. A similar office would meet the situation here.

"The question of the adverse effect on stream flow of the denudation of forest cover is probably one of the most important matters occupying the attention of engineers interested in water power, irrigation, water supply, navigation, or any other activity depending on water. Not only must the question be considered from a remedial point of view but also with a view to preventing existing forest cover at the headwaters of important streams from being burnt or improvidently logged.

"The particular situation in which I am officially interested is that in connection with the water powers of the Winnipeg River. The headwaters of this river are in the province of Ontario, and include the Lake of the Woods district. Fortunately this district abounds in large lake areas suitable for storage purposes and the land areas are, so far as I am able to learn, fairly well covered with forest growth. Owing to the location of this forest cover in close proximity to the prairie country, it has already become a prey to the unscientific lumberman, and it is only a matter of time until the commercial timber will be removed. Unless the lumbering operations are properly supervised and restricted and reforestation provided for, the present facilities that this district offers for storage and conservation of run-off will be dissipated.

"I am not aware that there is at the present time any forest reserve in the vicinity of the Lake of the Woods district, and am convinced that it would be in the best interest if the whole area were placed in a forest reserve in order that all logging operations may be under strict supervision of trained foresters, and also that adequate reforestation may be arranged for. Recommendations from the Conservation Committee of the Canadian Society of Civil Engineers to the proper authorities that such a reserve be created in the interest of the maximum advantageous use of the water resources flowing through and from the Lake of the Woods would surely be a matter worthy of consideration.

"There has been considerable discussion by the Conservation Committee regarding co-ordination or co-relation of the different hydrographic survey organizations of the various departments of the Dominion Service, and also of the Provincial Services. While the matter of internal organization of the hydrographic survey propaganda in Canada might not be one for the attention of the Committee, I do think the Committee might very well consider the advisability of recommending some systematic method of making the results of the various hydrographic survey organizations available to the public quickly and uniformly. My own opinion is that this could best be done by having one representative from each

Department of the Dominion Government connected with the hydro-graphic [illegible] work (a member of the Society) placed on a sub-committee of the Conservation Committee, with a view to giving this question special consideration."

Mr. A. J. McPherson, Regina, suggested the following matters and has promised a report thereon at a later date:

1. The development of methods of treating the large resources in the way of lignite scattered throughout Saskatchewan to make it more serviceable for the use of the people of the Province.

2. The collection and provision for industrial and commercial purposes of the sources of water supply in sections of the Province where the local supplies are shown to be becoming inadequate.

3. The development of the highways of the Province and the direction of the forces making for this so as to produce the largest results for the efforts expended.

4. The reclamation of various areas throughout the Province by drainage.

Mr. McPherson also enclosed an interesting report by Mr. R. O. Wynne-Roberts which deserves wide circulation as a very practical measure of conservation.*

Mr. C. E. W. Dodwell, Halifax, refers to a number of important matters as follows:—

"There is one very important matter that no doubt has engaged the attention not only of our Committee of the C. S. C. E. but the Commission of Conservation, of which you are Assistant Chairman; also I am aware that the Federal Government has done and is doing something in the matter, though I regret to say I have no definite knowledge and no official reports or blue books describing the work done or progress made I refer to the question of forestation, of which the importance is hard to over-estimate.

"If our C. S. C. E. Committee is not already in possession of full information in regard to the notable work that has been accomplished in Germany in forestation, I would suggest that steps be taken immediately to secure such information, with a view to the perfecting of a Forestry Bureau in Canada on similar lines. No doubt you are aware that forestry in Germany is a source of considerable revenue.

"In view of the rate at which timber is being used and our forests depleted, we should have thoroughly efficient and energetic forestry bureaus at work in every Province of the Dominion.

"I know that the Forestry Bureau of the United States Government at Washington is doing good work in the dissemination of literature and information in regard to forestry, and some months ago I obtained from the Forestry Office in Boston a number of interesting pamphlets on the subject.

"One very interesting feature of the question is the influence of forestation upon the climate of our North West. The whole matter is one of such great importance and interest that I feel under no obligation to apologise for mentioning it, though perhaps I should do so for my ignorance of what has been and is being done by the Federal Government.

"There is another important matter, that, so far as I am aware, has not engaged the attention of the Government and which certainly ought to do so.

"I dare say you often use alcohol in your domestic economy, for the purpose of making coffee or heating a chafing dish etc., and that you send to the druggist and pay 25 cents for about a pint or less of so-called methylated spirits, which when burning is often so evil smelling as to be almost unusable.

"In the United States, and I believe in most other civilized countries, denatured alcohol can be bought for about 50 cents per gallon, and it is coming into very general use for domestic cooking and heating purposes, and also for the production of power. There is a concern in New York called, I think, the Alcohol Utilities Company, which makes all kinds of utensils for the use of alcohol in cooking and heating as well as lamps for lighting purposes. The lamps are, of course, of the incandescent mantle type, and they are made of all powers, ranging from about 10 to about 500 c.p., the higher power lamps being, as they claim, very much cheaper in operation than electric lamps. I went through the place about a year ago and was amazed at the variety, simplicity and usefulness of the many utensils seen. Denatured alcohol in the United States is in fact a tremendous boon to the people, and I was told that some four or five immense distilleries in the United States, which, a few years ago were turning out whisky, are now confining their operations exclusively to the production of denatured alcohol, showing that, besides being a tremendous boon to the people, it is a profitable industry and no doubt one capable of very considerable expansion. Such an industry would, I think, be fully as suitable to Canada as it is to the United States, and there is no question whatever that it would be as great a boon here as it is proving to be in the States.

"I have discussed this matter with one or two Members of Parliament, who were all very favourably impressed with it, and they agreed with me that it was a matter that might very properly and profitably be taken up by the Government. My first suggestion would be that in any tariff revision that may come before the Government in the near future, the duty should be removed, in whole or part, from denatured alcohol for domestic, industrial or power purposes, and that encouragement in some way be given to the home production of this valuable article.

"If the Committee deem this matter worth an investigation I shall be glad to do what I can in procuring available information, so that we may be able at an early date to make it the subject of a report that will command the attention and interest of the Government and the people.

"Another matter of minor importance to the above has occurred to me as capable of development. There are in the country to-day many thousands of tons of sawdust lying in huge heaps at and around saw mills and up to the present time almost absolutely useless. It seems to me that some use should be found for this material. For instance, it might be mixed with a small proportion of some adhesive combustible substance, such as coal tar, crude oil or the refuse from oil distilleries, and compressed into briquettes for fuel; possibly some process might be discovered by which it could be converted into paper, but at any rate it might be given some value."

*Note.—Mr. Wynne-Roberts' paper is entitled "The Utilization of the Coal Deposits of Saskatchewan." The report is published by the Government of Saskatchewan and copies of the same may be obtained by those interested on application to Mr. A. J. McPherson, Chairman, Highway Commission, Regina, Sask.

THE ST. LAWRENCE BRIDGE COMPANY'S SHOPS

DESCRIPTION OF THE PLANT BUILT AND EQUIPPED SPECIALLY FOR THE FABRICATION OF THE QUEBEC BRIDGE AND OF THE FIELD EQUIPMENT FOR ITS ERECTION

THE St. Lawrence Bridge Company, Limited, was incorporated August 5th, 1910, with an authorized capital stock of $3,000,000, one-half of which was subscribed for by the Dominion Bridge Company, of Montreal, and one-half by the Canadian Bridge Company, of Walkerville, Ont. Its directors are Messrs. Phelps Johnson, Chas. Cassils, G. H. Duggan, F. L. Wauklum, and J. F. Weber, of Montreal; and Messrs. F. C. McMath, Willard Pope, and B. S. Colburne, of Walkerville. The president is Mr. Phelps Johnson; vice-president, Mr. Chas. Cassils; secretary and treasurer, Mr. J. F. Weber; superintendent, Mr. W. P. Ladd.

The company was organized to tender for the fabrication and erection of the superstructure of the Quebec Bridge, and was awarded the contract in April, 1911. This contract, at a figure approximating $8,650,000, was awarded on the basis of designs submitted by the company, differing from those of the Board of Engineers which had been appointed by the Dominion Government in 1908 to draft designs for a new structure at substantially the same location as stood the partially erected structure which collapsed on August 27th, 1907.

Articles dealing in a comparative way with the accepted design have appeared in *The Canadian Engineer* and elsewhere, as have also descriptions of the design and construction of the substructure. The accepted design, being larger and heavier than that of the old structure, necessitated the construction of new piers and abutments throughout. These are now completed and the approach spans are also in place.

Before giving a description of the company's fabricating plant, the outstanding features of the design of the bridge will be briefly reviewed, to outline the immensity of the problem which devolved upon the company with the award of the contract.

The Quebec Bridge will cross the St. Lawrence River at Neilsonville, about 8 miles above Quebec. It will have a total length of 3,239 ft. between abutments, with clear height of 150 ft. above high tide, while the main posts will rise to a height of 343½ ft. above water. Besides two 515-ft. anchor arm spans 310 ft. deep, it will have a 1,800-ft. centre span consisting of two 580-ft. cantilever arms connected by suspended trusses 640 ft. long. The superstructure will have two lines of pin-connected trusses, in vertical planes 88 ft. apart. It will be made of carbon and nickel steel, with members of a maximum shop length of about 90 ft. and shop weight of 140 tons.

Realizing that the erection of the superstructure was the chief problem connected with it, and that the peculiar design of the bridge would evolve many unprecedented engineering features; and fully cognizant of the effect of the stresses introduced by erection in the old structure, the St. Lawrence Bridge Company decided to build and equip a shop specifically for the work. The great size and weight of many of the truss members, the accuracy of workmanship, and the rapidity of construction required, left little alternative. The result is the present plant, which has cost about $1,000,000 to build. It is situated between Montreal and Lachine, about one mile from the plant of the Dominion Bridge Company, and on the Grand Trunk and the Canadian Pacific Railway. The accompanying figures, some of which are taken from an article in June 7th, 1913, issue of *Engineering Record*, illustrate the shop in plan and elevation. To this article we are also indebted for much of the following information descriptive of the works.

The plant is equipped for the fabrication of 2,000 tons per month of heavy riveted members. It has machine tools for precise work in finishing bearing surfaces up to 10 ft. square and boring long pin-holes up to 4 ft. in diameter through compression members and eye-bars. All fabrication is done in a single long shop, with receiving and shipping storage yards at both ends, with a comprehensive system of surface tracks and traveling cranes. Electric drive is used throughout, individual motors driving most of the principal machine tools and groups of smaller tools.

General Design of Main Shop.—The main building is 660 ft. long, and 160 ft. wide, for 440 ft. of its length and 190 ft. wide for the remainder, with a lean-to to be described later on. It has a concrete roof carried on transverse trusses spaced 20 ft. apart. At the receiving end these trusses have bottom-chord runways for girder cranes and are themselves supported on the wall columns of the building and on a line of centre longitudinal trusses of 100-ft. span, thus eliminating all but three interior obstructing columns in a length of 400 ft. At the other end of the shop all of the roof trusses are supported directly on columns, which support also the crane runways, parallel to the axis of the building.

The columns rest on concrete piers, with footings proportioned for the maximum pressure on bedrock at a depth of about 4 ft. below the surface. The roof trusses have spans of 60, 75 and 80 ft. and are of heavy construction, with riveted connections at panel points and full-depth connections to the columns. The structural steel-work weighs about 2,000 tons and was fabricated by the Structural Steel Company and erected by the Dominion Bridge Company.

The exterior walls are of brick, with concrete foundations, with a stone water table about 8 ft. above the surface of the ground. The floor is of concrete, with timber sleepers for the track rails and provisions for anchoring or clamping movable equipment.

The shop has a great window surface area and is provided with arc and incandescent lighting. It is heated by exhaust steam in a fan blast system designed to maintain a temperature of 50 deg. with the mercury at 20 deg. below zero outside.

Construction was commenced in 1911, and the foundations were finished before the end of the year. The erection of the steel-work was commenced in 1912, and fabrication of steel for the bridge commenced in the spring of 1913.

The plant arrangement provides for the entrance of raw material at one end of the main shop and the performance of successive fabricating operations as it passes continuously through the shop parallel to the longitudinal axis, until the finished members are delivered at the op-

posite end. The equipment is arranged for the amount of the different classes of work in the order of the successive operations, so that the average proportion of different classes of work will keep the shop uniformly

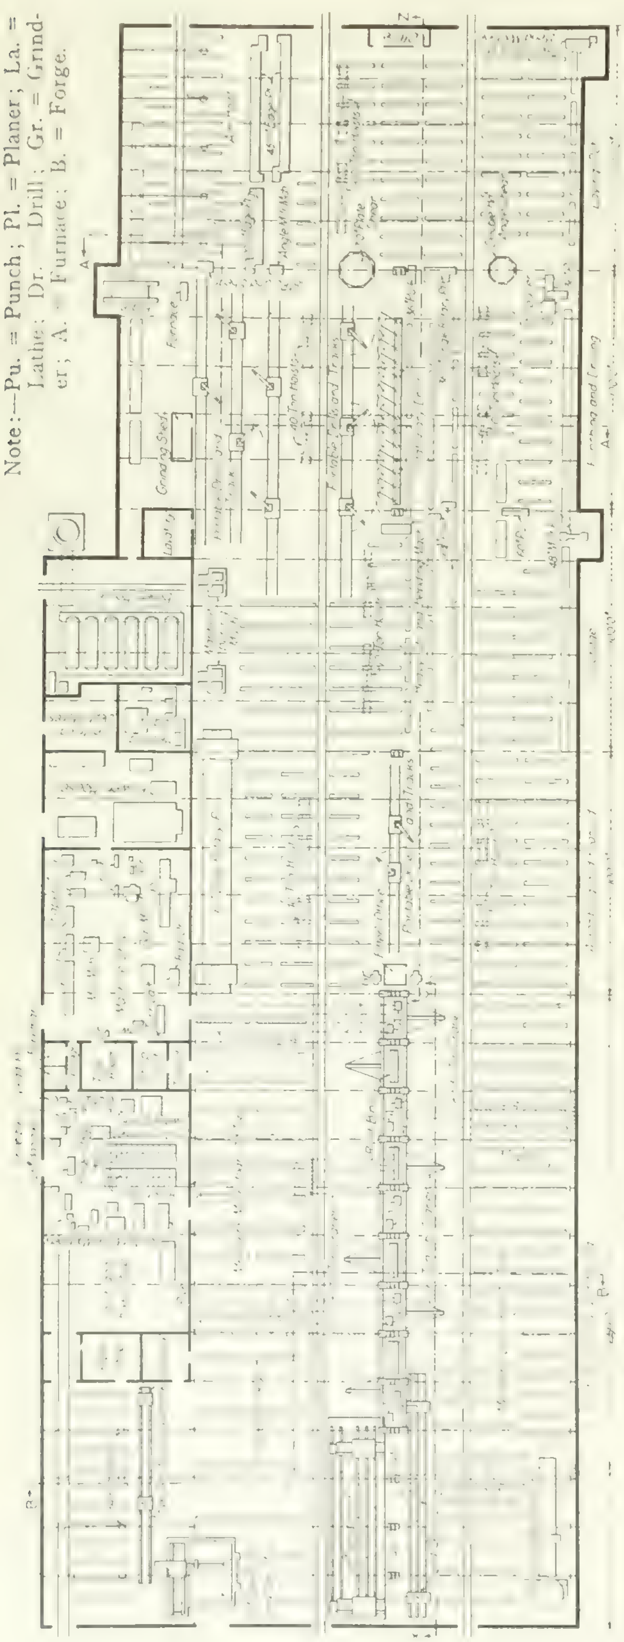

Fig. 1.—Floor Plan of Main Shop, Showing Position of Tracks, Columns, Trusses, and Machines.

busy with a constant progress of material and little lost motion or interference. Materials and supplies are received and products shipped on two tracks running through the plant parallel to the main building and commanded at both ends by cranes traversing the building. These serve the receiving storage yard at one end and the shipping storage yard at the other end of the shop.

Material is handled in the receiving yard by two 7½-ton trolley hoists on a 15-ton electric traveling crane, of 90-ft. span, with runways 500 ft. long, crossing three lines of narrow-gauge service tracks which enter the shop, two of them passing through to the other end and across the shipping yard.

Description by Panels.—The material entering the shop from the storage yard is placed on wooden skids with concrete foundations transverse to the shop axis, which occupy a large portion of the first 100-ft. panel. This panel is 160 ft. wide between main columns, besides a 30-ft. lean-to on one side, as shown in Fig. 2. It has a clear height of 21 ft. from the floor to the underside of the 80-ft. roof trusses, carried at one end of the centre-longitudinal truss. This construction is duplicated in the next panel. In the next two panels the width of the lean-to is increased to 60 ft., giving the entire shop a width of 220 ft.

In the first panel there is on one side a straightening machine with 80-ft. roller tables at each end and three large edge planers. They are served by two 10-ton assembling hoists traveling the full width of the panel on the bottom chords of alternate pairs of roof trusses. In the lean-to there is a 60-ft. roller table at one end of a set of rolls for straightening plates up to 120 in. wide, which are commanded by five 3-ton pneumatic trolley

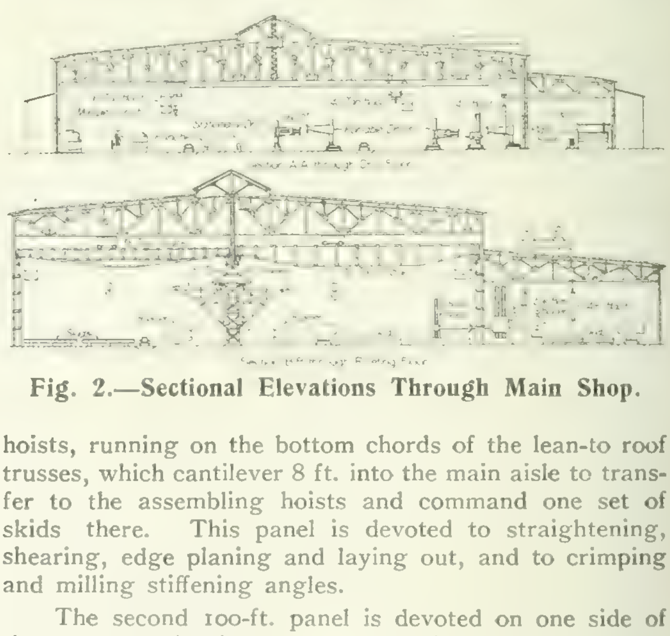

Fig. 2.—Sectional Elevations Through Main Shop.

hoists, running on the bottom chords of the lean-to roof trusses, which cantilever 8 ft. into the main aisle to transfer to the assembling hoists and command one set of skids there. This panel is devoted to straightening, shearing, edge planing and laying out, and to crimping and milling stiffening angles.

The second 100-ft. panel is devoted on one side of the centre longitudinal truss to punching and on the other side to drilling, and is served by two 40-ton and two 10-ton assembling hoists arranged, as are all of the others in this end of the building, like those in the first panel. The punching equipment is quite standard, and the machines, together with the shears, are arranged principally on the transverse lines at the ends of the panel so as to leave the interior space as much unobstructed as possible between main columns.

The special drilling plant includes 16 stationary heavy radial drills mounted on a long foundation, parallel to the shop axis under the centre truss, and 24 similar portable drills, each mounted on an individual truck, which travels on a portable track that can be clamped to the concrete floor. All of the drills have 6-ft. arms with vertical adjustments, have locking devices to the track,

and are driven by variable-speed motors. There are also 12 horizontal drills mounted on trucks to work in conjunction with the radial drills and for later use in drilling the field splices in the main members. It is the intention to assemble the members in temporary sections up to 40-ton weight and drill the rivet holes en masse.

In the third 100-ft. panel, as in the remainder of the shop, except the last 125 ft., the lean-to is separated from the main shop by a solid wall, reducing the width of the shop itself to 160 ft. In the third panel there are located two manhole boring machines to rough-cut pin-holes from 10 to 45 in. in diameter. The remainder of the space there is occupied by longitudinal and transverse skids for the storage of drills and punched materials, which are handled by two 10-ton assembling hoists.

On one side of the fourth 100-ft. panel there is installed a 60-in. duplex rotary planer with a bed 110 ft. long. Provision was also made for the installation as required of the portable drills forming the reeming plant, and the remainder of the space in this panel is devoted to assembling members up to 80 tons, which are handled by two 10-ton and two 40-ton assembling hoists.

Beyond the fourth panel there is a centre longitudinal row of columns, 20 ft. apart, dividing the shop into a 75-ft. and an 85-ft. aisle, and the height of the roof is increased to 38½ ft. from the floor to the under side of the roof trusses. Both of these aisles are 260 ft. long, and the width of the 85-ft. aisle is increased to 145 ft. for a distance of 100 ft. at the extremity by the inclusion of the lean-to space, the dividing wall being here removed and the addition thus provided being occupied by a duplex eye-bar boring machine with a bed 100 ft. long. The 85-ft. aisle is equipped with two 70-ton and one 35-ton cranes of 85-ft. span, traveling the full length of the aisle and serving to handle members weighing above 70 tons each, which will be fabricated here. At the end of this aisle there is a special horizontal boring machine for large shoes and main members, with a capacity for a 45-in. hole 11 ft. long. Each saddle has a vertical movement of 12½ ft., while the main column has a horizontal traverse of 23 ft., thus enabling it to bore several holes in the same piece at one setting.

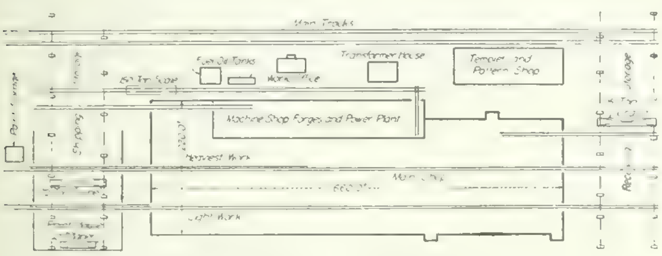

Fig. 3.—Arrangement of Buildings and Tracks.

Opposite the boring machine in the same aisle is a duplex vertical and horizontal planing machine for finishing the ends of large compression members for which rotary planing is not permissible. One of its heads is stationary, while the other has a power traverse on the 25 x 100-ft. bed, to enable it to be set for various lengths of members. The heads can make a 10-ft. cut in either a vertical or horizontal direction and are equipped with patent tool holders for cutting in the four directions, on both direct and return strokes. This machine will finish the 7 x 10-ft. bottom-chord pieces 42 ft. long, which weight 140 tons each.

The 75-ft. aisle is equipped with two 35-ton traveling cranes, one single-headed, 60-in. rotary planer with a 50-ft. bed and a duplex horizontal-chord boring machine with two movable heads on a bed 100 ft. long. This aisle is intended for the fabrication of members weighing less than 70 tons each.

Members in both the 75-ft. and 85-ft. aisles will be riveted by various pneumatic yoke machines with gaps of from 24 to 72 in., handled by 6-ton traveling jib cranes, with runways 180 ft. long on both sides of the centre row of columns. These cranes are 20 ft. high above the floor, with a clearance of about 18 ft. beyond the columns, and are special in that the bottoms are provided with vertical bearing wheels to carry the weight and with inclined reaction wheels in the planes of the braces to receive the thrust on special T-shaped tracks, inclined about 45 deg. to the vertical.

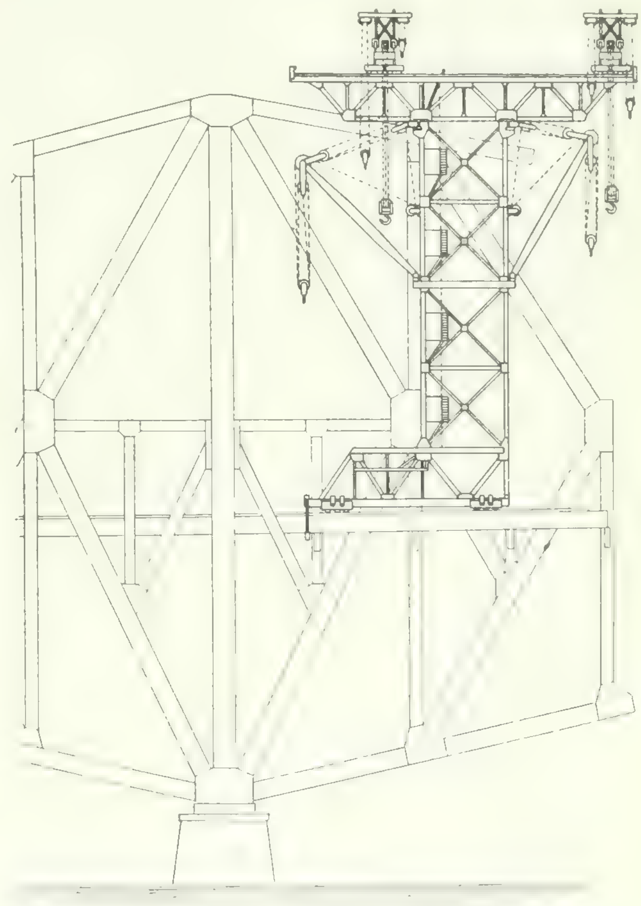

Fig. 4.—Side View of Erection Tower, on Cantilever.

The 60 x 340-ft. enclosed portion of the lean-to is occupied by the bolt and rivet shop, forge shop, the 60 x 80-ft. machine shop, generator and compressor room, boilers, coils, and fans for the heating plant, and by store-rooms, lavatory, offices, etc.

At the end of the shop there is a storage yard for finished members, which is commanded by a 70-ton crane of 80 ft. span, with runways 500 ft. long. One end of the runway is enclosed by a shed 140 ft. wide and 180 ft. long, open at one end, which provides shelter for painting and for a 120 x 120-in. x 30 ft. surface planer for finishing the larger shoes.

Opposite the laying-out panel of the shop is the 60 x 176-ft. two-story brick and steel template and pattern shop, equipped with power-driven wood-working tools and having benches nearly 100 ft. long. There is also a 30 x 50-ft. transformer house and a 25 x 45-ft. office building. The designing offices of the company are in Montreal.

Equipment at Bridge Site.—This reference to the equipment for the fabrication of the Quebec Bridge would not be complete without an outline of some of the methods which have been adopted for the placing of the various members after they arrive at the site. From foregoing descriptions of the design, it will be remembered that it was the intention to erect each of the cantilevers as an entirely separate structure, with its individual erection equipment. The centre span, weighing about 6,000 tons, will be completely assembled on barges at the river bank. When the time arrives for its erection, all navigation will be stopped at this point on the river. The span will then be floated into position, and will be hoisted by hydraulic power into its proper place, 150 ft. above the river.

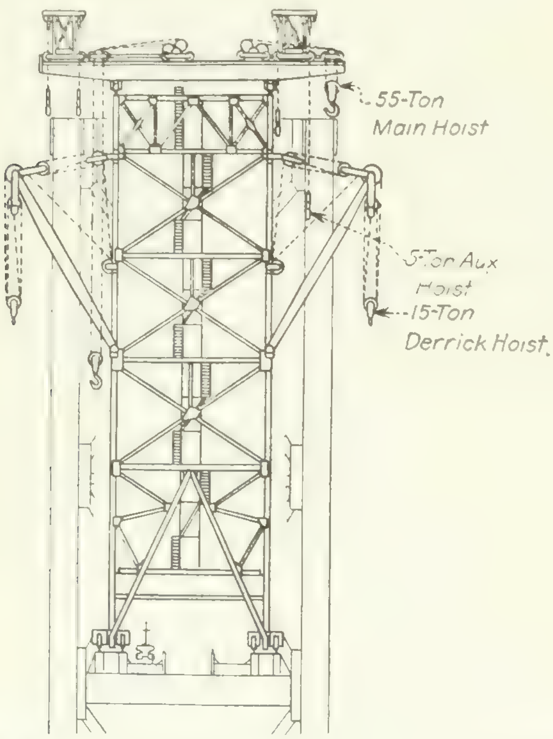

Fig. 5.—End Elevation of Erection Tower, Showing Location of Hoists.

As for this cantilever erection, the scheme and the design of the erection equipment are unparalleled in bridge engineering, and display the greatest ingenuity and exhaustive scientific investigation for the solution of the problem.

The erection of each cantilever of the bridge will be executed by means of a huge erection tower which will be carried by the cantilever itself, and moved outward along the bridge structure as its length extends from shore. These towers are of heavy steel construction with a height of 200 ft. from the carriage to the summit. Each travels by four trucks of six wheels each, spanning a double-track railway spur for the bringing in of bridge material. Each tower weighs approximately 840 tons. At this the weight is a minimum, careful experiment having been carried out to secure requisite strength without undue weight. The crane girders which project over the travellers are of nickel steel.

Each erection tower is equipped with a 90-ft. 15-ton derrick hoist on each of its four corners. Two traveling cranes, each of which carries two 55-ton main hoists and two auxiliary gantry cranes, operate at the top of the tower. Each of these gantry cranes is equipped with two 5-ton hoists, making eight 5-ton hoists for each tower.

With the exception of the travel of the four auxiliary gantry cranes all operations are electrically driven. The motor equipment of each tower is shown in Table I.

Table I.—Motor Equipment for Each Erection Tower.

Crane.	Service.	No. of motors.	Motor h.p.
15-ton derrick hoist	Hoist	4	50
	Swing	4	5
55-ton main traveler	Hoist	4	80
	Bridge	2	16
	Trolley	4	5
5-ton auxiliary gantry	Hoist	8	20
Total		26	752

This does not include, however, the motive drive of the main erection towers themselves along the cantilevers, this movement being accomplished by two of the 50-h.p. motors, which form the hoisting power for the 15-ton derrick hoists.

The electrical energy for these motors is brought to the site on each side of the river by high-tension transmission, where it is stepped down and converted by motor-generator sets to 250-volt d.c. Each sub-station receives its supply from separate systems and they are joined by submerged cables. Each is of sufficient capacity to supply the requirements of all the machinery as well as the air compressors which, in themselves, require in the neighborhood of 1,600 h.p. The object in converting from a.c. to d.c. is to afford better control and to permit the use of dynamic braking, which is necessary in the lowering of such enormous loads into position. The different speeds required during the placing of material are secured by resistances in series with the motor, which, during the period of retardation acts as a generator. The resistances are in the form of cast grids located at the base of the tower where their weight and size do not interfere with operations. Over 5,000 grids are required for this method of regulation.

The dynamic braking action is available for use only in retarding motion, while the motor armature is still rotating. When motion ceases the load is held stationary by magnetic brake. Safety devices on the important hoists prevent the load to over-travel when it nears its position.

Fig. 4 shows part of an uncompleted cantilever carrying one of these erection towers. Fig. 5 is an end view of the tower alone. These views are reproduced from the *Engineering Magazine* for December, 1913, containing an article by H. F. Stratton, descriptive of the erection equipment for the Quebec Bridge. The method of procedure, as described by Mr. Stratton is as follows:

It is planned to erect the north anchor arm over staging by what might be designated, purely for convenience, the first erection tower. When the north anchor arm has been erected, work will start on the south anchor arm by the use of the second erection tower. While the south anchor arm is being erected, the first erection tower will be at work on the north cantilever arm, and this will be finished substantially when the south anchor arm is completed. The first erection tower will then be taken down and reassembled at a point two miles below the bridge site, where it will be again set up for assembling the suspended centre span on barges. During the building of the suspended span, the second erection tower will be assembling the south cantilever arm, and these processes will be completed at substantially the same time. There then re-

mains merely the transportation of the centre span to the bridge site, and its subsequent elevation into place.

On each erection tower there will be built an operating platform at about the second-floor level, from which a clear view can be secured of the material as it comes in on flat cars and as it is later elevated by the cranes and finally properly placed in its permanent position. A house will be built in the centre of this platform for protecting the control apparatus from the weather, except that portion of it which is actually manipulated by the workmen, which will be out-doors on the platform. Six men will be stationed on the operating platform and two men on each of the main cranes at the top of the tower. To secure the proper co-operation by quick, effective communication between these widely separated workmen, a complete telephone system is to be installed with a central switchboard and permanent connections to the shore. An electrically operated passenger elevator will regularly serve the different floor levels.

The following is a brief description of the method of erecting any typical part of the structure. The member is brought in on flat cars underneath the erection tower, and by proper manipulation is elevated and located by two, or possibly four, of the 55-ton main hoists. The pin is then placed and suspended in position by means of one of the 5-ton auxiliary hoists, and a large ram for driving the pin is suspended from another 5-ton auxiliary hoist. The pins are equipped with hardened steel pilots which guide them through the links as they are being driven home to their places.

The date of completion of the bridge has been estimated to be either the year 1917 or 1918.

VALUE OF MELTING POINT TEST OF BITUMINOUS MATERIALS.*

By H. B. Pullar, Assoc. Am. Soc. C.E.
of the H. B. Pullar Co. (Detroit), Engineering Chemists

As in the case of a number of other tests for bituminous materials, the value of the melting point test has been much questioned, and there is considerable variation of opinion among engineers and chemists interested in the testing of bituminous materials as to the value of this test. Some believe that it is an important one in determining the quality and suitability of a bituminous material, some merely use it in conjunction with other tests as a means of identification, while still other authorities do not use the test in their work, and strongly recommend its total elimination from all bituminous work.

On account of bituminous materials being mixtures of hydrocarbons and not true solids, they have no true melting point, and some arbitrary method must be adopted. As nearly all bituminous materials must be heated before being used in actual work, the melting point was naturally one of the first tests to be thought of and many different arbitrary methods were used by chemists for running this test. One of the first of these methods and the one which the writer first used, was what is known as the "Capillary Tube" method. This method consists of using a capillary tube about six inches long, having an outside diameter of about 5 mm. and an inside diameter of about 3 mm. The capillary tube was drawn to a point and sealed at one end. A piece of the bituminous material to be tested was then rolled out until it was small enough to be inserted into the capillary tube. The tube with the material inserted was then placed in a bath of cotton-seed oil or sulphuric acid and the temperature raised at the rate of about 5° F. per minute. When small specks of melted material were noticed on the sides of the tube the first reading was taken and this was designated as "Starts to Melt." The next reading was then taken when the small specks of melted material began to run together and this was designated as "Starts to Run." The third and last reading was taken when the tube was entirely coated with the material and was uniform throughout. This was designated at "Melts All Over." This test was only used for a short time and was not found satisfactory as the results were variable and depended a great deal on a personal equation. The thickness of the tube and the method in which it was constructed also had considerable to do with the results obtained. This method has now been abandoned entirely by those interested in the testing of bituminous materials.

Another of the old melting point tests which was commonly used, was known as the "Mercury Test." The method for making this test is described by Mr. Clifford Richardson in his book "The Asphalt Pavement," as follows:—

"A crystallizing dish, about 2¼ inches in diameter and with 1½-inch sides, filled with clean mercury to a distance of ¼ inch from the top, is placed over a 20-mesh wire gauze and heated by a small flame protected from draughts by a chimney. On the surface of the mercury is placed a thin microscopic cover-glass, No. 2-0, carrying the specimen of asphalt under examination. When dealing with hard asphalts that can be ground rather coarsely, several fragments which will pass a 40-mesh sieve and be retained on a 50-mesh sieve (about .50 mm. diameter) are spread on the cover glass and placed upon the surface of the mercury, covered with a funnel, from which the stem has been cut and the thermometer passed through the orifice until the bulb is immersed in the mercury. It is held in position by a clamp attached to the ring-stand, holding the dish. Under the dish a burner is placed that can be regulated to a small flame and heat so that the rise of temperature will be from three to five degrees per minute. In a short time it will be noticed that the specimens will have changed from the brown or brownish-black color of the powder to that more nearly approaching the original, with a slight rounding of the individual grains. On further heating these globules flow together and form a thin sheet on the glass. The point at which the specimen begins to flow, as indicated by the thermometer, is noted as the melting or flowing point.

"Asphalts that cannot be ground are softened and pulled out to a thread and cut into small pieces, about 1 cubic mm. Several pieces should be placed on the glass together, as one will serve as a check on the other, and thereby lessen the chance of error. The softening point may be noted by the rounding of the particles and the beginning of the flow, or when the specimen begins to spread out, which is always at the point of contact with the cover-glass,

*Paper read before the convention of the American Association for the Advancement of Science at Atlanta, Ga., Dec. 31st, 1913.

is set down as the flowing point or the temperature at which the specimen will melt."

This test was a big improvement on the capillary tube method, but there were also many objections, and as in the case of the capillary tube test, the results were dependent to a great extent on a personal factor.

On account of the rapid development in the bituminous industry new and more scientific methods of testing were desired, and as the result of investigations and tests, two new methods for the taking of melting point have been developed. These methods are more scientific and different chemists in various parts of the country are able to obtain comparable results on the same sample or on the same class of bituminous materials. These two methods are known as the "Cube Method" and the "Ring and Ball Method." The "Cube Method" was recommended for use by a special bituminous committee of the American Society of Civil Engineers, and at the present time is probably used more than any other method. The determination of the melting point by the cube is as follows:—

> A ½-in. cube of the material is placed on the short arm of a No. 12 B. & S. gauge wire bent at right angle and placed in a 400 c.c. Jena glass beaker, tall form. The bottom of the cube to be placed 1 in. from the bottom of the beaker on which is a small piece of filter paper. The beaker is placed in a 600 c.c. common form beaker containing cottonseed oil. The temperature is raised at the rate of 5° C. per minute. When the cube just touches the bottom of the beaker the melting point is read from a thermometer placed within the bulb even with the cube.

The "Ring and Ball" method has been used by a number of chemists and is used more extensively in the testing of tars than asphalts. This determination is made as follows:—

> A brass cylinder ¼ in. high and ⅝ in. inside diameter is supported by wire in beakers as in cube method. The cylinder is filled with bitumen and a ⅜ in. bicycle ball placed on top. The temperature is raised at the rate of 5° C. per minute and when the ball falls to the bottom of the beaker the melting point is read from the thermometer.

There are a number of other methods in use by various chemists throughout the country and in different localities, one of the most popular of these being known as the "Thermometer Test," which consists of placing the sample of bituminous material around the bulb of the thermometer, inserting the thermometer in a test tube and emersing the test tube in an oil or acid bath. The bath is then heated at the rate of about 5° F. per minute, and the temperature at which the bituminous material drops from the thermometer, is taken as the melting point.

Another of the well-known tests is what is known as the "Kramer & Sarrow" method, but on account of its being little used, details will not be given.

As can be seen from the foregoing statements, there are a number of methods used for making melting points. Most of them have been developed during the last five years. On account of the many different methods which have been used and the fact that until very recently none of the methods were of sufficient scientific accuracy to make the results dependable, the value of the melting point test can well be questioned, and in the opinion of the writer, the results which have been obtained are absolutely of no value unless the details of the method used are given.

The results obtained by using the different methods of taking the melting point, are not comparable, and in a recent patent suit this was brought out very clearly; the results on the same sample varying considerably, depending upon the method used and the chemist making the test. On the same sample three different chemists varied more than 60° F. on a material having a melting point of 300° F. With this wide variation in results on the same sample, the melting point test is of little or no value.

In the writer's opinion, the melting point test, like other tests for bituminous materials, if properly used, is of considerable importance. The melting point test indicates in a large measure the lowest possible temperature at which a bituminous material must be heated before using; for instance, a blown oil product having a penetration of about 75 and having a melting point of 200° F., will require heating to at least 350° F. before using in a practical way, whereas an asphalt obtained by the direct distillation of oil having a penetration of 75 but a melting point of only 130° F. would require a heat of not more than 250° F. to 275° F. to be the proper temperature for use, and at a higher heat would likely be injured.

The melting point also is of considerable importance and value in identifying different bituminous materials or the different processes used in the production of these materials. This point is clearly brought out by Mr. Prevost Hubbard in his interpretation of the melting point test which is as follows: (Blanchard & Drowne's Text Book on Highway Engineering).

> "A determination of the melting point of solid bitumens is mainly of value as a means of identification and for control work on the part of manufacturers. The melting point of a bitumen is directly related to its hardness and brittleness, but the relations are not the same for all classes. Thus, at normal temperature, a blown oil with a melting point of 50 degrees Centigrade is neither hard nor brittle, while a tar pitch is both. As the melting point rises, however, they both become harder and more brittle. The climate under which a bitumen is to serve as a road binder, should be considered in connection with its melting point and this is particularly true of tar products."

In view of the fact that there are now two tests which are comparable and which are recognized as being capable of giving uniform results, the value of the melting point test from the present time should be of greater importance than ever before, and will enable intelligent comparisons of materials to be made.

In conclusion, the writer would state that in his opinion, the melting point test is of considerable value and should not be eliminated as one of the tests for bituminous materials, that when properly used, it is of importance in identifying different materials, that when properly used, it tends to give certain indications as to the quality of the bituminous materials under examination. It must, however, be understood that the results obtained at the present time with this test are not comparable with the results obtained even a few years ago, and that in all cases where the melting point is given, the method of testing should be indicated.

With these points in mind the melting point test is of importance and will be of greater importance in the testing of bituminous materials.

THE UNDERGROUND SURVEY WORK FOR THE MOUNT ROYAL TUNNEL

PRECISE ALIGNMENT AND LEVELLING METHODS THE ACCURACY OF WHICH WAS SO CLEARLY MANIFESTED AT THE MEETING OF THE HEADINGS ON DECEMBER 10TH, 1913—THE REWARD OF PERSEVERANCE IN THE ELIMINATION OF ERROR—INSTRUMENTS AND ACCESSORIES USED

By J. L. BUSFIELD, B.Sc., A.C.G.I., A.M. Can. Soc. C.E.

At 7 o'clock on the morning of December 10th, the culmination of the precise surveying and aligning of the Canadian Northern Mount Royal Tunnel was reached by the meeting of the bottom headings from opposite sides of the mountain, with an error of only ¾ in. in alignment and ¼ in. in grade. This exactitude is the result of over 1⅓ years' careful surveying, many calculations and much patience.

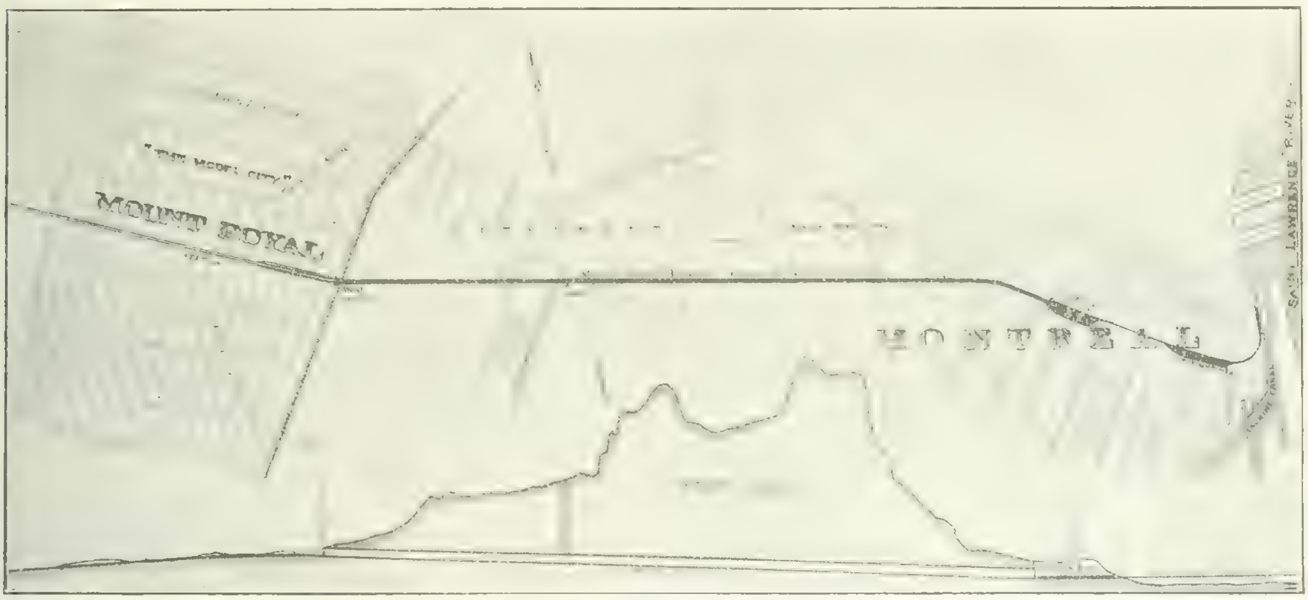

Fig. 1.—Plan and Profile of Tunnel Location.

In order to fully understand the nature of the alignment work performed it will be necessary to refer to Fig. 1, which shows the location in plan and profile of the tunnel. It will be seen that the tunnel is located on two tangents, connected by a 2-deg. curve in the neighborhood of Sherbrooke Street. The main tangent through the mountain is 2.8 mi. long. The method adopted for the construction of the tunnel was that of driving a bottom heading approximately 8 ft. high and 12 ft. wide. With the object of driving the headings from as many points as possible, one was driven towards the city from the West Portal; a shaft was sunk at Maplewood Ave. a depth of 250 ft. to the level of the tunnel, and headings were driven both ways from this shaft; and, at the city end a fourth was started westwards from the bottom of a 55-ft. shaft close to Dorchester and St. Monique Streets. The location of these shafts and the West Portal is shown in Fig. 1.

Previous to the actual commencement of the construction work, the relative location of the important points along the route of the tunnel was obtained by base line traverses around the mountain.* The long tangent was also very precisely located over the mountain, and permanent monuments established at all the transit points. (These were finally reduced to three in number between the West Portal and Sherbrooke St.) East of Sherbrooke Street the centre line of the tunnel was to be coincident with the centre line of McGill College Ave., but as the shaft at Dorchester St. was to be located to the north of this centre line, as shown in Fig. 2, it was found best to reference a line 33,678 ft. to the north of, and parallel to, the centre line of the Avenue, by means of points on the roofs of the most solid structures intersected by this line. It intersected the main tunnel tangent at a point on the roof of Strathcona Hall on Sherbrooke St., and the angle at this point was read a number of times with a 10-second transit until the final intersection angle of 21° 15′ 48″.6 was adopted. The location of this point was tied in to the co-ordinated survey lines. In this way its distance from the West Portal and from the location for the Dorchester Shaft was computed.

The actual work of driving the headings was commenced in July, 1912, when an opening was made under the C.P.R. tracks at the West Portal. In order to give

* For description of these base line traverses and of the precautions against inaccuracies [illegible], see *The Canadian Engineer* for February 27th, 191[illegible]

line for this heading, a concrete monument was built in the open cut west of the Portal at a point so located that it was possible for a transit to be sighted over the C.P.R. tracks on to the mountain to a foresight, and the depressed and sighted along the centre line of the heading (see Fig. 3). Shortly after this heading had been commenced, the Maplewood and Dorchester shafts were started. The former of these could not be located immediately over the tunnel centre line, so a parallel line 24 ft. to the south of it was established by carefully measured offsets, one on the side of the mountain above the shaft, the other on the flat roof of a convenient building between the shaft and West Portal. A transit tower (Fig. 4) was built adjacent to the shaft so that a transit could be set on the offset line by direct sights on to the two offset points, and could be also sighted on to the top of the shaft for setting the plumbing wires.

The alignment was transferred to the centre line of the heading and run both east and west from the shaft.

Monuments and Scales.—Before proceeding with a description of the methods used in laying out the lines described above, note should be made of a piece of apparatus used very frequently, and found almost invaluable in the alignment work. This was a brass scale fitted with a sliding vernier, as shown in Fig. 5. Whenever it was necessary to obtain the average of a number of points set by a transit, one of these scales would be used. Whenever required for this purpose they were rigidly attached to the roof timbers or to plugs set into the roof of the heading, as shown, with plumb-bobs suspended from the sliding verniers in front of "light boxes" or illuminated screens. These scales were only used as a means of obtaining averages and for temporarily holding the line. As soon as a good set of readings was obtained on any scale, the line was transferred to a permanent monument in the floor of the heading. These monuments were mostly of the type illustrated in Fig. 6, being made of a piece of gas pipe with a small piece of solid brass rod rivetted tightly into the top of the pipe. For giving the centre line at the working face, "spads," also illustrated in Fig. 6, were set in the roof every 50 or 60 ft.

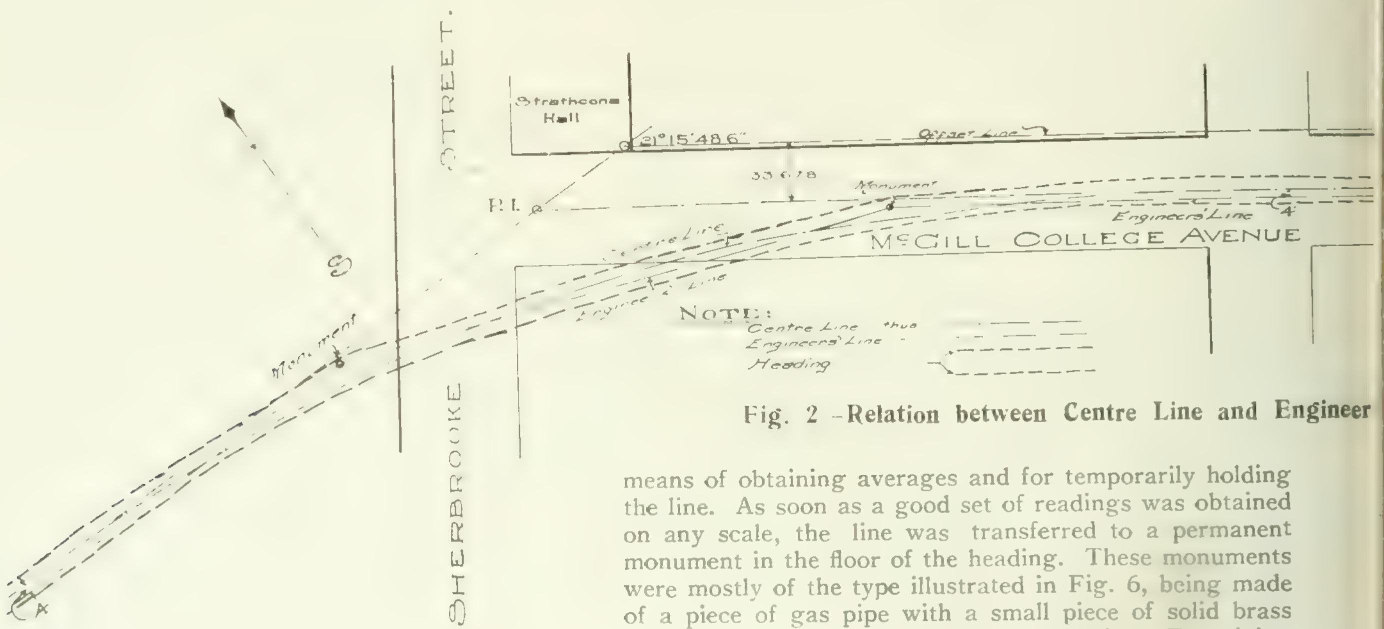

Fig. 2—Relation between Centre Line and Engineer

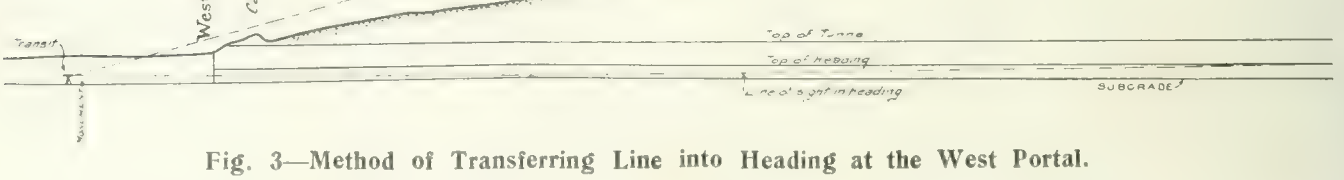

Fig. 3—Method of Transferring Line into Heading at the West Portal.

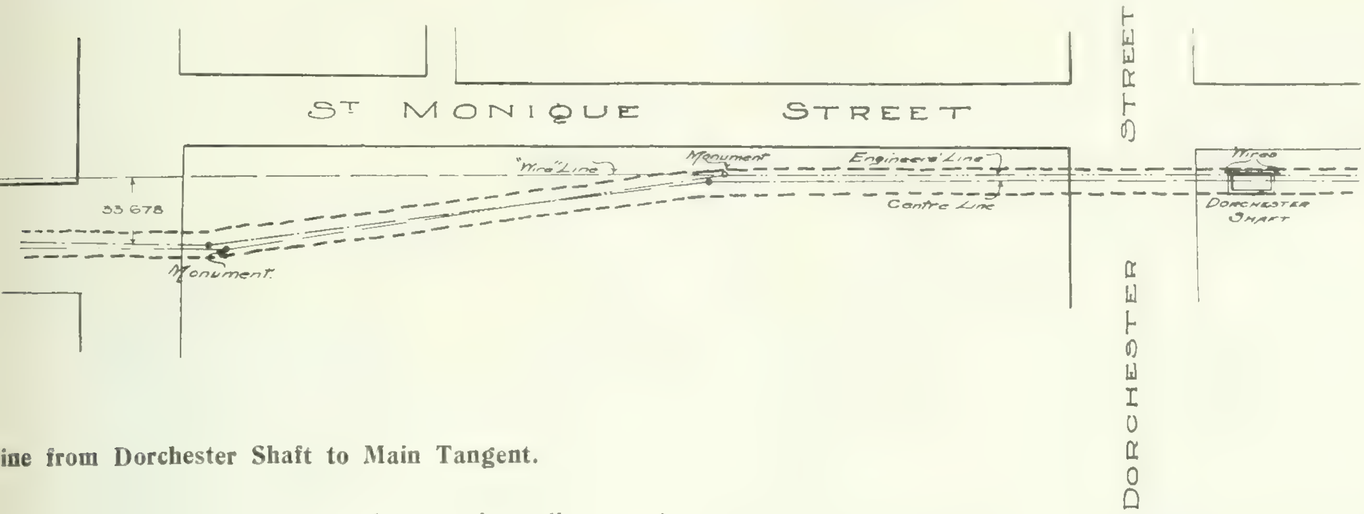
After the westerly heading had been driven 2,100 ft., a junction was made with the one from the West Portal, meeting with an error of less than 1-16 in. in alignment. After this junction had been made, the centre line was carried through from the West Portal to the working face in the heading, being driven east from the shaft. At the city end, as shown in Fig. 2, it was found advisable to run an engineer's line in the heading independent of the centre line. This enabled the alignment to be transferred up McGill College Ave. and around the 2-deg. curve onto the main tangent with a minimum of 4 angles. throughout the tunnel. They were also used for giving elevations and chainage.

Shaft Plumbing.—For transferring the survey lines down the shafts, No. 8 steel piano wires were used, being suspended as far apart as the limits of the shafts would permit. They were hung from reels attached to solid wooden frames, as shown in Fig. 7, and were passed over a notch in a tangent screw on the front of the frame by means of which they were finally adjusted to their exact position at their upper ends. The two wires were very carefully set on line at the surface by a transit, and

an instrument man was kept on watch throughout a series of observations. This precaution was fully justified, as frequently the wires would be jarred very slightly off line by a careless laborer or by some other cause. At the lower ends of the wires, 12-lb. and 30-lb. weights were attached at the Dorchester and Maplewood shafts, respectively. The weights were immersed in water and covered over, as shown in Fig. 8, in order to reduce the vibrations to a minimum. It was impossible to eliminate the oscillation entirely, and the centre of the swing of the wire always had to be estimated by the instrument man. In producing the line into the heading, the instrument man set the transit on line as close as he could estimate by eye, about 10 ft. from the nearest wire, and would then proceed to buck into line until, when he had sighted on the near wire (taking the centre of swing) and produced the line of sight on to the further wire, the latter would be bisected by the transit cross hair. It must be understood that in doing this when one wire was in focus the other was so much out of focus it was entirely invisible. At least 2 scales had been previously set up at each shaft, one being as far away as possible from the wires. When the instrument man had got the transit set on line he would proceed to set the plumb-bob at each scale on the line of his cross hair. When this was done the reading at each vernier would be recorded to the nearest 1,000th ft. This operation was repeated at each shaft a great many times. The observers at transits and scales were frequently changed, and the transit was reversed and set off line between readings. A lateral adjuster was frequently used to facilitate bucking into line. Care was always taken in placing the light boxes and plumb-bobs so that the minimum amount of movement of the telescope was necessary. At the Dorchester shaft it was possible to locate these in such a way that the telescope could be clamped to the verticle circle, and the only movement necessary was that of the focusing screw.



ine from Dorchester Shaft to Main Tangent.

Fig. 4.—Transit Tower at Maplewood Shaft.

At the foot of the Maplewood shaft it was only possible to locate the scales about 80 ft. apart (Fig. 9), and it was necessary to measure the 24-ft. offsets to the north at each scale on to monuments on the tunnel centre line. The precision of the 24-ft. distance was not so important as it was to have the two offsets absolutely identical. A variation of only one 100th ft. in one of these offsets would have meant an error of 3 in. at the meeting point 2,100 ft. away. This, added to a possible error from an inaccuracy in the wire line, might have made quite an appreciable error at the meeting point. A rigid wooden frame was made with needle points set 24 ft. apart and set up at each offset monument. The line was then transferred on to the monuments by means of a transit.

Turning Angles.—In the heading from the Dorchester shaft, 4 angles had to be turned off very precisely, as the exactitude of the main tangent depended largely on the accuracy of these angles. In setting off one of these angles a 10-sec. transit was first set up over the angle point, and in order to eliminate any errors due to inaccurate centering of the plumb-bob, etc., another transit was invariably used to set up the larger transit vertically over the angle point. The transitman would then turn off the angle roughly and have a small mark made on the foresight monument. The precise angle to this rough point would then be obtained by "wrapping up" the angle 5 times, thus giving a reading approximately to 2 seconds. The method of "wrapping up" is as follows: Clamp the plates at zero, sight on to the backsight; (2) unclamp the upper plate, sight on to foresight, and take the first reading of the angle; (3) leaving the upper plate still clamped at the first angle, unclamp the lower plate and turn back on to the backsight again; (4) unclamp the upper plate again and turn to foresight. Repeat the whole operation until 5 readings have been obtained. The last reading, divided by five, should be very close to the first reading and will be a value of the angle practically to 2 sec. if the work has been carefully performed.

After the precise angle to the rough point had been obtained in this manner, by taking the difference between this angle and the angle required, and also knowing the distance between the angle point and the foresight, it

was possible to calculate the amount the true point should be to right or to left of the preliminary mark made on the monument. After a new point had been obtained in this way, the angle was again wrapped up five times by different observers, and the whole operation repeated until there was no possibility of error of even 1 sec. in the angle.

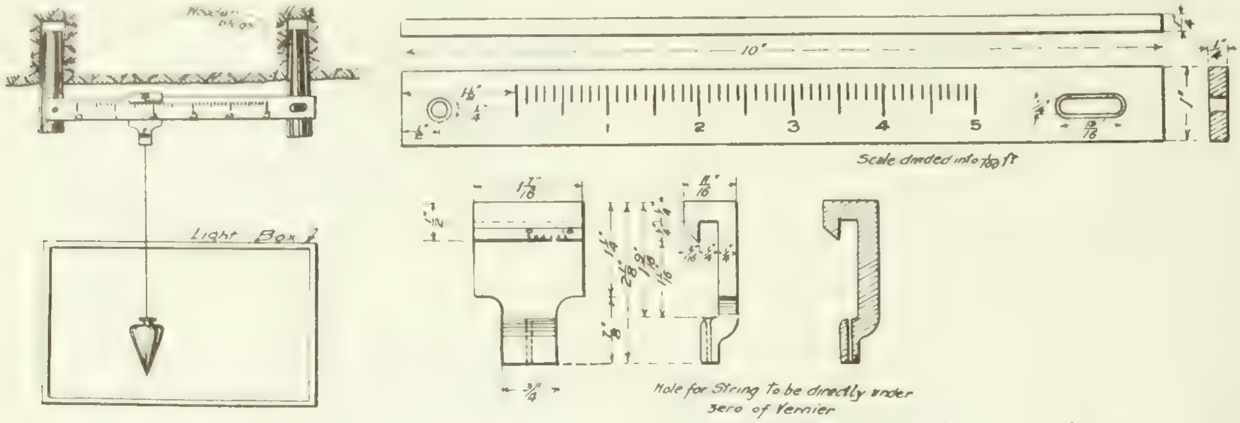


Fig. 5.—Detail of Brass Scale and Method of Fixing in Roof of Heading (on left).

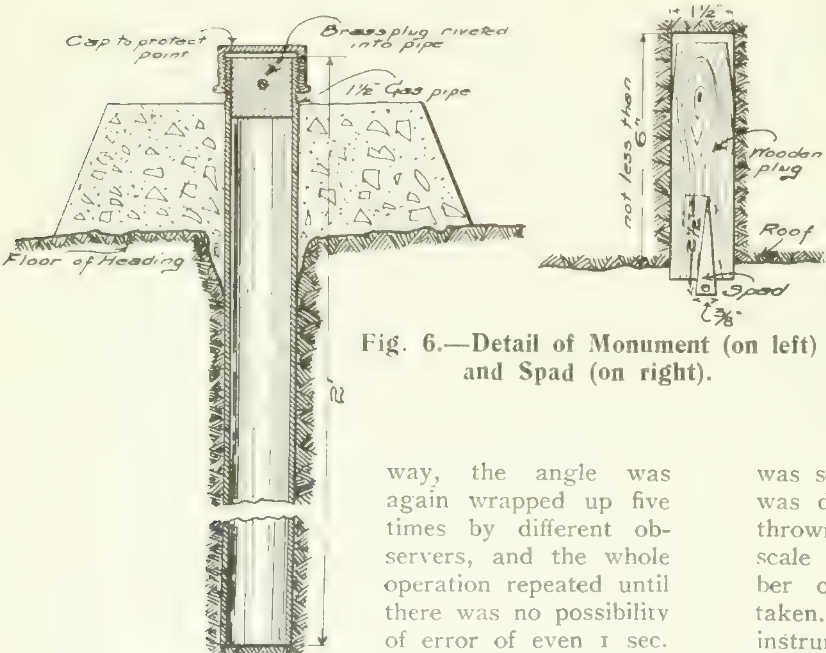

Fig. 6.—Detail of Monument (on left) and Spad (on right).

Producing Tangents.—After the last angle had been turned off to a point as far away as possible, the tangent had to be produced westwards. At the same time the tangent was being gradually prolonged eastwards from the West Portal. In producing a line from any 2 monuments a scale was set up at the foresight and the transit was set up adjacent to the intermediate monument. Instead of being set up over this monument by means of a plumb-bob, the method described in the article previously referred to was used. The transit was set up about 10 ft. away from the monument and bucked into line until the cross hair bisected both the backsight and the punch mark at the monument at which the transit was set up. After this was done the line was thrown ahead to the scale and a large number of readings were taken. By reversing the instrument between each set and having different transitmen take readings, instrumental and personal errors were reduced to the minimum.

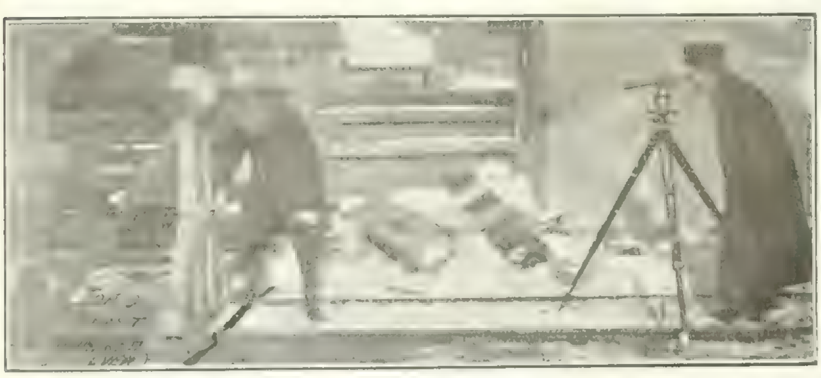

Fig. 7.—Setting Wire on Line at Surface.

Fig. 8.—Taking Line From Wires at Foot of Shaft.

Targets.—In producing the tangents it was naturally advisable to use as long sights as possible, and for sights of over 1,000 to 1,200 ft. the ordinary plumb-bob was not satisfactory. For taking these long sights 2 types of targets were used, from both of which good results were obtained on sights as long as ½ mile, in a smoky heading. The one shown in Fig. 10 was used at points where a fixed backsight was required. The other, shown in Fig. 11, was used at foresight stations where a movable target was required, being attached to a sliding vernier at a scale. The former was made by cutting square holes out of a

piece of sheet tin, with their diagonals located exactly on a straight line, and the tin attached to a piece of wood with similar, but larger, holes cut in it. This target was attached with horizontal and lateral adjustments to the front of a large, light box, containing sockets for about 15 lamps. In practice this box and target were set up so that the centre line was exactly over the punch mark on the monument, and was

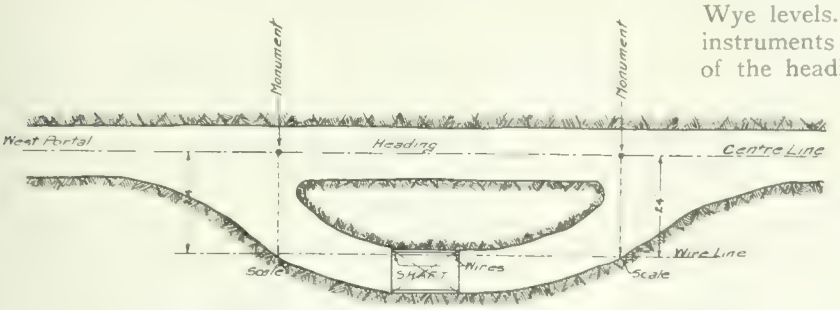

Fig. 9—Alignment at Bottom of Maplewood Shaft.

set vertical by means of a transit set up a short distance away. Once set up the target was clamped and the box kept steady by rocks or by nailing to convenient timbers.

The type of target shown on Fig. 11 was designed by A. F. Duguid, transit man of the party on the Western Division, as a substitute for the plumb-bob in places where a movable target was necessary. Canadian and United States patents have been applied for in connection with it. The one originally used was made from an 18-in. length of 2½-in. seamless steel pipe, by cutting in it pairs of slots 2 in. long and 180° apart at regular intervals. These slots were accurately cut to one 100th in., and the hole in the cap through which the suspending cord was passed was very accurately centered. The ends were weighted with lead in order to give the target stability. When suspended in front of a light box, this target presents a silhouette which encloses a series of bright areas, varying in width. If the vertical cross hair of the transit is made to bisect the bright areas, the line of sight will be in the same vertical plane as the point of suspension. It is immaterial from which direction the target is sighted, as there will always be a number of bright areas in view.

Levelling.—Although the work of levelling through the tunnel, and of keeping the floor of the headings to the correct grade, was not so difficult to carry out as the alignment work, it was even more essential that it should be carried out accurately. An error of 3 in. in line would not have been a very serious matter, but 3 in. difference in grade would have meant 3 in. to have been taken off one heading floor, or an additional amount of concrete or ballast to have been used on the other side. The permanent monuments already described were used for bench marks throughout the tunnel. In levelling between 2 monuments the level was set up equidistant between turning points about 100 ft. from the instrument. The difference in elevation of the turn points was taken by 3 independent operations of setting up, and a mean of all three readings taken. New York rods with sliding targets reading to one 1,000th ft. were used. All elevations were run separately by different observers, and differences of 100th ft., or more, were not accepted. For the working face elevations were taken on each spad. Their chainage being known, the height of the spad above sub-grade could be computed, and by sighting across footrules, or by any other method the foremen might prefer, a line could be marked across the working face a certain number of feet above sub-grade. All elevations were referred to the datum of the Montreal Harbor Commissioners.

Instruments, Etc.—For ordinary work, such as putting in spads and rough surveys, a 30-second transit with a 6¼-in. plate was used; but for all precise work, turning off tunnel angles, etc., a 10-second instrument with a 7-in. plate was used. The levels were all taken with 18-in. Wye levels. Considering the rough use to which these instruments were subjected, due to the dirt and drippings of the headings, it was remarkable how well they kept their adjustments. It should also be borne in mind that the great majority of the work was done under very adverse conditions of atmosphere and surroundings.

A great variety of light boxes was used, all of simple construction, being made from empty boxes, tin cans, and anything to which lamp sockets and reflectors could conveniently be attached.

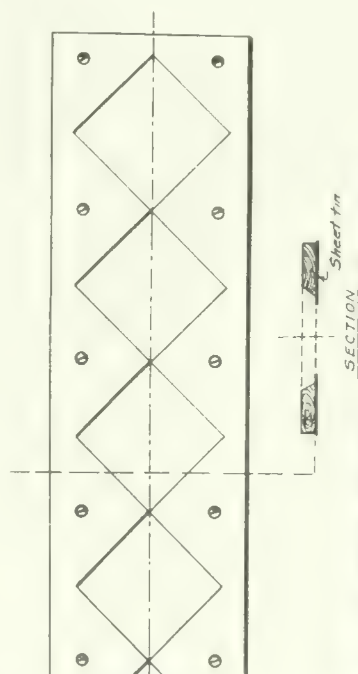

Fig. 10—Target for Fixed Back-sight.

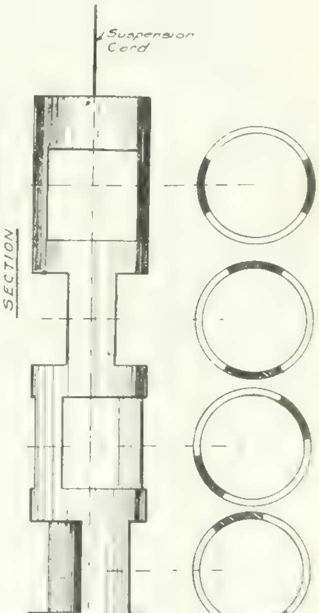

Fig. 11—Target for Movable Fore-sight.

Personnel.—The whole of the alignment work was carried out under the direction of Mr. Howell T. Fisher, M. Can. Soc. C.E., Tunnel Engineer; Mr. R. S. Basset, Asst. Engineer, was in charge of the alignment and survey work for the Western Division and the writer for the Eastern Division.

THE CONSTRUCTION OF CREOSOTED WOOD BLOCK PAVEMENTS.*

By R. S. Manley.

A CREOSOTED wood block pavement should show no evidences of wear for many years if the proper materials are used, and if they are assembled in the proper way. The correct depth of base, or foundation, varies with the soil conditions, but the materials forming this concrete foundation and the methods of mixing are in such common use as to be standard and easily secured.

We are interested principally in the construction placed on top of the concrete. The principal causes of defects of more or less serious nature are (1) irregular or uneven surface due (a) to careless laying, (b) to shifting of sand cushion, (c) breaking or settling of concrete. (2) Expansion difficulties due to the entrance of water into the blocks, either by way of the joints or from below.

The first (irregular or uneven surface) is death to any paving material, because a depression in the surface holds water, and repeated churnings of wagon wheels in the depression are bound to cause an enlargement and deepening of the depression.

To avoid (a) the concrete should be mixed quite wet and finished smoothly with a flat wooden spreader, which gives a surface practically as even and uniform as could be obtained by templet. On this should be spread from one-half to one inch of clean sand, making the sand cushion conform to the contour of the finished street. On this place the blocks quite closely together, roll thoroughly until a perfect surface with no inequalities has been obtained and until the blocks are firmly in place. It will require a great deal of rolling to accomplish this, but the end justifies the means. After this fill all joints two-thirds full of hot bituminous filler of such melting point as is suited to climatic conditions, and spread a thin coating of sand thereon. The use of the bituminous filler is, in my estimation, the most important of all. It converts the street into an effective watershed which, without absorbing any of the water, directs it into storm sewers or other drainage paths. Should any water remain on the surface the wind and the sun, both good evaporative agencies, will rapidly dissipate it.

Now you have an absolutely even surface, waterproofed and converted into a watershed. This surface cannot be worn by traffic, because the pressure of wheels is even and regular, and there is no dropping or jolting of wheels entering and leaving low spots. The blocks are laid tightly together, so that there is no wearing at the joints. There can be no change in the sand cushion as long as the surface remains intact, a solid sheet, in fact, of wood block cemented together by the filler, and consequently the difficulty of shifting cushion is avoided. It is assumed that the concrete is sufficiently strong so that it will not break or settle. In planning the depth, any error should be on the side of too great, rather than too little depth.

Expansion difficulties are eliminated by the use of bituminous filler, for there can be no expansion without absorption of water, and no absorption of water when all rainfall is conducted quickly to drainage sewers. In addition to this it must be remembered that with the bituminous filler each block is surrounded by an individual expansion joint.

The other way of constructing wood block surface which is sometimes recommended is to provide a mixed sand and cement cushion and sand-filled joints or interstices. The sand and cement cushion does not give the opportunity for absolutely smooth surface that the sand cushion gives and is considerably more costly. The sand filler in the joints allows moisture to be absorbed in the pavement, and ultimately this moisture gets into the blocks and trouble ensues. It is only on extremely heavy traffic streets that sand can be used as a filler without expecting some expansion difficulties sooner or later. The proof of the pudding is the eating, and the proof of theories of wood block construction lie in the actual occurrences on the street.

* Read at the annual meeting of the American Wood Preservers' Association, Jan. 22nd, 1914.

MAINTENANCE OF ENGLISH ROADS.

Although the following figures relate to the mileage and cost of maintenance of English roads are for the year 1911, they will be found interesting nevertheless by men in highway work. They appeared recently in connection with the British taxation returns.

It will be seen that the total mileage of roads in England and Wales in 1911 was 150,671, of which 27,754 miles were main roads, the cost of maintenance and repair of which amounted to $14,365,750. Some 122,917 miles were ordinary or district roads which cost, in maintenance and repair for the year, $28,396,000. These sums are exclusive of works of road improvement, and if such be added the total outlay on the roads for the year under review was $73,862,000.

Description of Roads.	Mileage Year 1910-11.	Expenditure on Maintenance and Repairs 1910-11.	Average Per Mile. 1910-11.	Average Per Mile. 1909-10.
1. Main roads repaired by County Councils:				
(i.) In urban districts	631	$[illegible]28,8[illegible]3.64	$1,156.08	$1,108.08
(ii.) In rural districts	17,723	7,594,036.74	427.68	388.80
2. Main roads repaired, on behalf of County Councils, by Councils of:				
(i.) Municipal boroughs	1,243	1,368,532.26	1,103.22	1,074.06
(ii.) Urban districts other than boroughs	2,315	2,375,533.98	1,025.46	967.14
(iii.) Rural districts	5,842	2,298,726.59	393.66	364.50
3. Roads (not being main roads) repaired by Councils of:	4,871	2,626,062.12	539.46	515.16
(i.) Municipal boroughs	11,411	4,712,275.44	413.10	370.08
(ii.) Urban districts other than boroughs	95,077	11,239,158.24	116.64	111.78
(iii.) Rural districts	9,366	6,257,133.36	665.82	631.80
4. Public roads and streets repaired by:				
(i.) Councils of county boroughs	2,144	3,387,084.66	1,579.50	1,545.48
(ii.) Councils of metropolitan boroughs	48	174,289.32	3,630.42	3,965.76

HAMILTON WEST END SEWAGE DISPOSAL WORKS

DESIGN AND CONSTRUCTION DETAILS OF THIS PART OF AN EXTENSIVE SEWERAGE SYSTEM FOR ENTIRE CITY—OUTLINE OF THE SYSTEM AND ITS CHIEF COMPONENTS

By BERNARD E. T. ELLIS, C.E.

Assistant Engineer, in charge of Main Drainage Works, Hamilton

THE City of Hamilton, with a population of over 100,000, is situated at the head of Lake Ontario. The sewers are all on the combined system, as a result of which the discharge of sewage fluctuates considerably. The topography of the city is such that at least two main outfalls are necessary, owing to the Dundurn Ridge, which runs north and south, dividing the city into western and eastern drainage areas, which may be classed as residential and manufacturing districts respectively. In 1911 the west end main trunk sewer was built to calculations for the combined system of drainage, with a maximum drainage area of 1,225 acres.

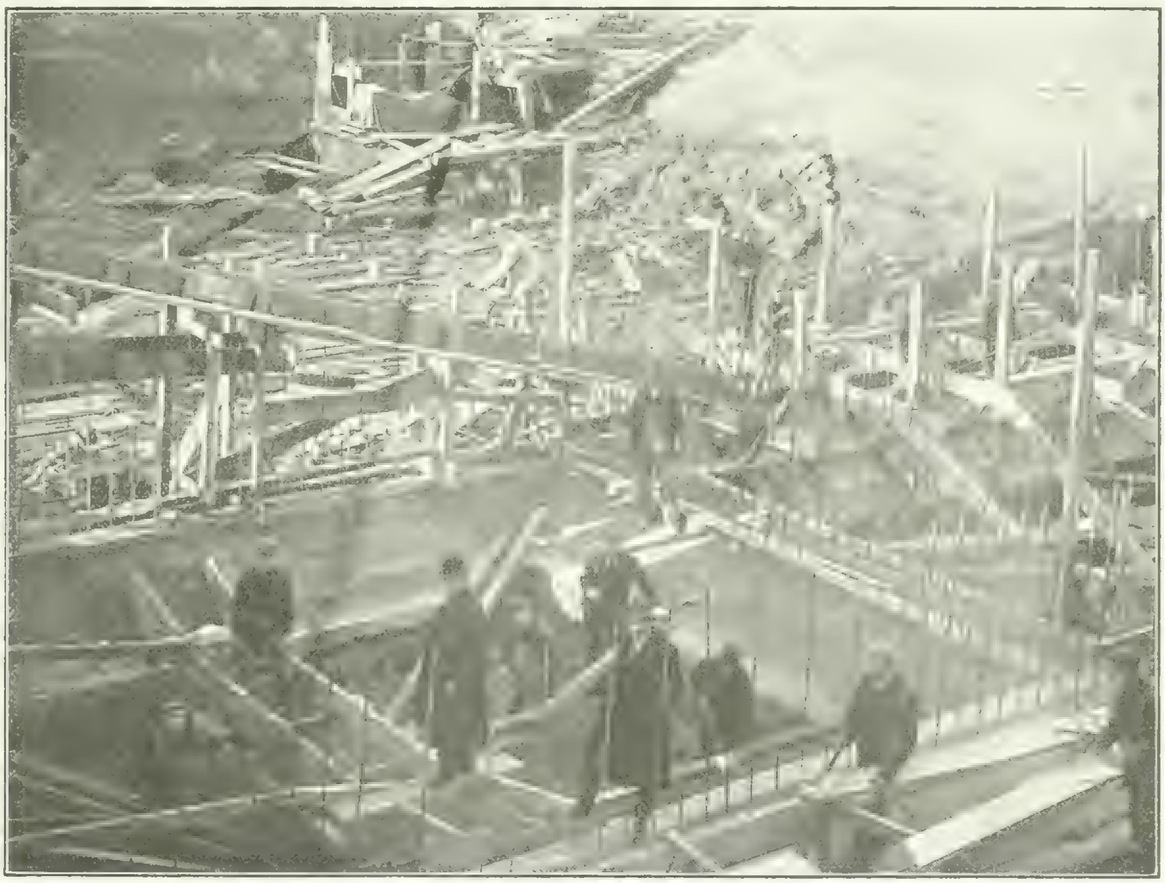

Fig. 1.—Sedimentation Tank Bottom and Sump Under Construction; Clear Water Drainage Scheme.

Upon this area the calculation for these disposal works was principally based. Allowing, for the area being fully built upon, owing to the rapid growth of the city, a total daily dry-weather flow of 5,880,000 gal. of sewage was the volume considered for treatment. Calculations from weir gaugings, taken at the outfall in the main sewer, gave the present daily dry-weather flow to be approximately 3,000,000 gal. In character the sewage to be treated is purely a weak domestic one. As it is to be carried to the disposal site by gravitation, in sewers having sufficient grade to ensure a good self-cleaning velocity, it will be discharged at the works in a comparatively fresh condition.

The new disposal works were designed to treat the sewage from this entire west end drainage area. They comprise: coarse screens; grit chambers; continuous flow, 2-story sedimentation tanks; dosing chambers; sprinkling filters, provided with nozzles, throwing a circular spray under a variable head given by the dosing chambers. Fig. 2 shows the general layout.

For the present, only part of the original scheme is being carried out, to remove the suspended solids from the whole of its sewage, to reduce the bulk by septic decomposition. The final treatment of the clarified effluent by filtration, after further consideration was abandoned, as the effluent discharging in a marsh as a considerable distance from its inlet through the Des Jardines Canal to the Bay, was considered to be sufficiently oxidized before reaching it. The secondary filtration may be added at some future date if found necessary by local changes in the district.

Treatment of Sewage—Main Intake Chamber. The main intake chamber off the 6½-ft. main sewer leading into the site of the disposal works was designed with a storm overflow weir, at such an elevation that during storms anything above 3 times the normal dry-weather flow would discharge over it, into the existing brick sewer, which is at present the main outlet for the untreated sewage from the West End drainage area into the marsh. The connections are shown in Figs. 3 and 4. When the new disposal plant is in full operation this old brick sewer will act as a storm overflow sewer only.

The end of this chamber is constructed as an inspection manhole, fitted with sluice gate for closing down the works whenever necessary.

Screening Chamber.—The C.I. screen consists of bars spaced at ½-in. centres, placed at an angle of 45° to the flow, and only intended to arrest the bulky floating mineral matter, which can easily be removed, by means of hand raking, into the steel channel iron supporting it.

Grit Chambers.—The grit chambers, as shown in Figs. 6 and 7, are built in series of three, each 30 ft. x 4 ft., and a variable depth (minimum being 4 ft.). They are equipped with a by-pass arrangement, controlled by penstocks for diverting the flow as required when in operation.

The normal velocity of these grit chambers is calculated for not less than 1 ft. per sec., and stop-logs have been inserted in the main walls to regulate the velocity according to the variable flow. They were designed with the object of being operated separately. They are not intended to remove putrescible organic matter, but simply for the settlement of sand, and any other heavy mineral matter. A large percentage of streets drained in this district are at present paved with macadam, and, being on the combined sewerage system, a considerable amount of sand, silt, and street washings will find its way into the sewers after heavy storms.

The cleansing of these chambers may be done whenever required, being easily accomplished in the following manner: The sewage is drained off by means of the 6-in. unjointed, vitrified pipes, covered with broken gravel, laid in the V-shaped channels, leading from a main sump to the manhole where each draw-off pipe is fitted with a separate valve. This manhole is connected to the temporary 9-in. effluent pipe, through which the sewage is discharged to the main effluent pipe emptying into the marsh. The chambers are then cleaned out by hand. It is intended to use the sand, after washing (if necessary) for the finished layer required on the filter media for the sludge beds.

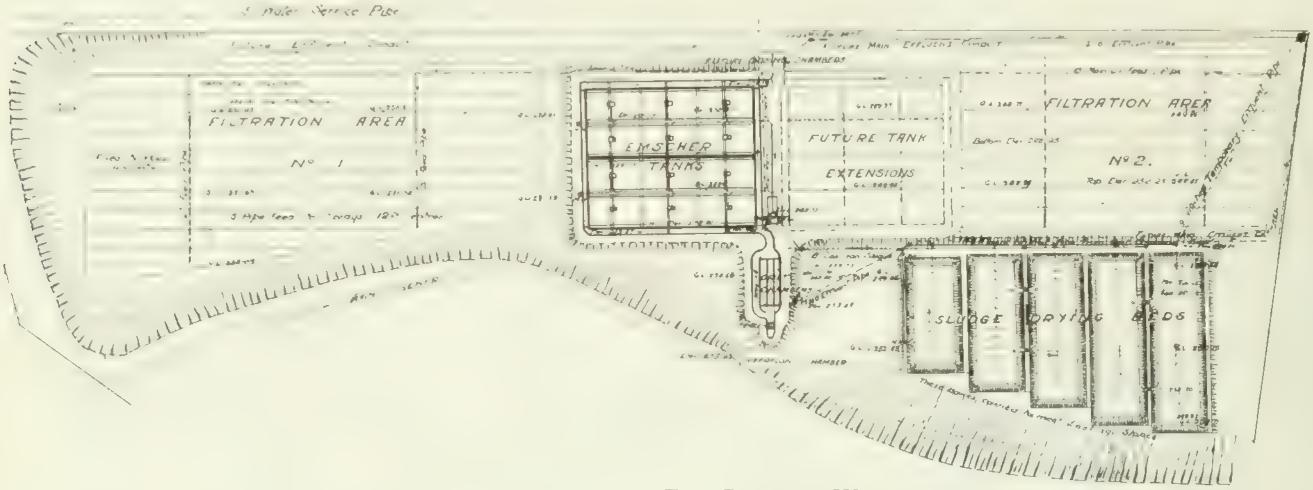

Fig. 2.—General Layout of West End Disposal Works, Hamilton.

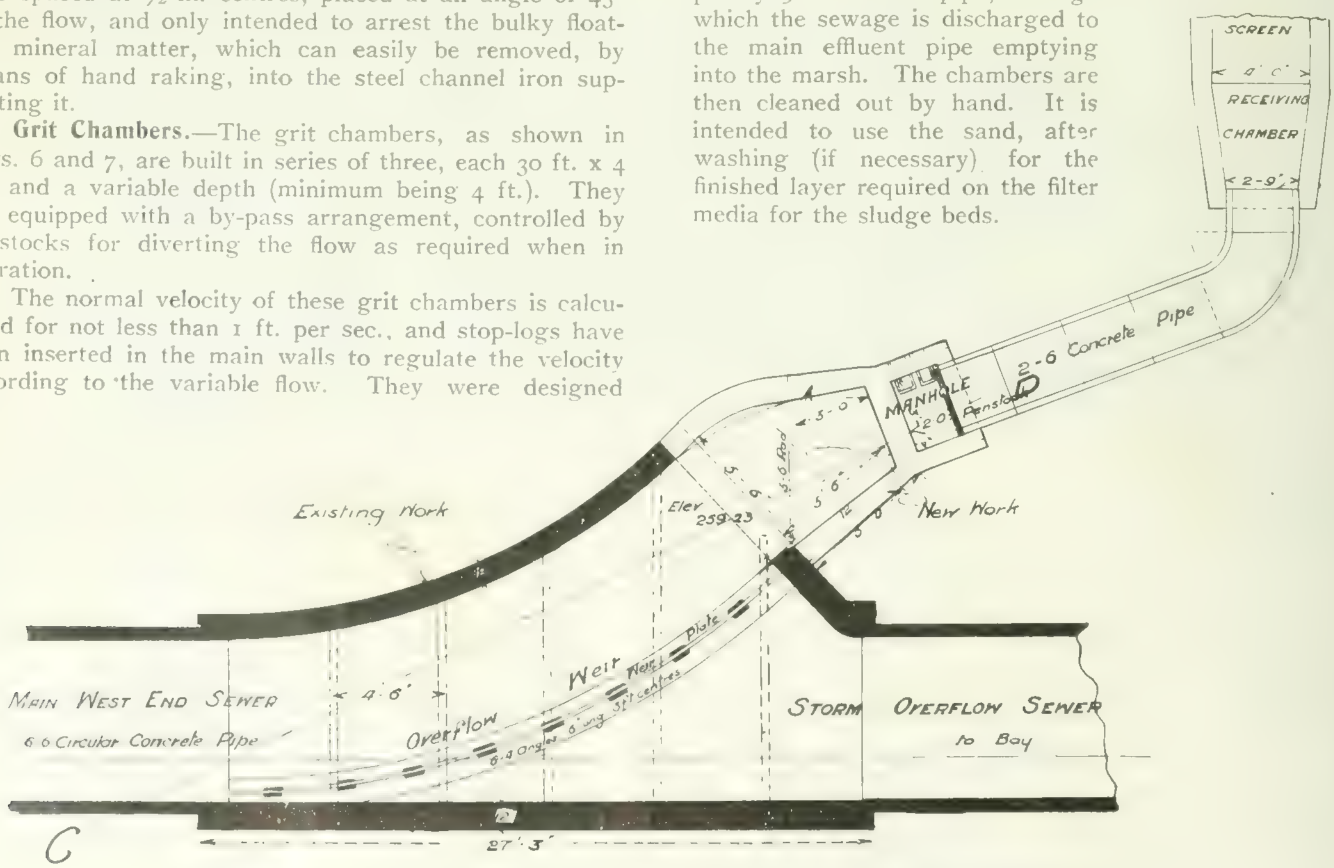

Fig. 3.—Plan of Overflow Chamber and Connection to Tanks from Main Sewer.

porary 9-in. effluent pipe, through which the sewage is discharged to the main effluent pipe emptying into the marsh. The chambers are then cleaned out by hand. It is intended to use the sand, after washing (if necessary), for the finished layer required on the filter media for the sludge beds.

Sedimentation Tanks.—After depositing the mineral matter, the sewage passes along the feeder conduits to the 2-story sedimentation tanks, and by means of the different gates located at the positions shown in Fig. 5, scum boards at both ends into the clarified effluent conduit, which discharges into the main effluent pipe leading to the marsh.

Each tank is rectangular in shape and consists of a sedimentation tank and a sludge digestion chamber. The one is separated from the other by means of a reinforced concrete sludge apron, at an angle of 60° to the horizontal in order to facilitate the automatic discharge of sludge into the lower compartment. These overlap each other, and have an 8-in. horizontal opening, which is

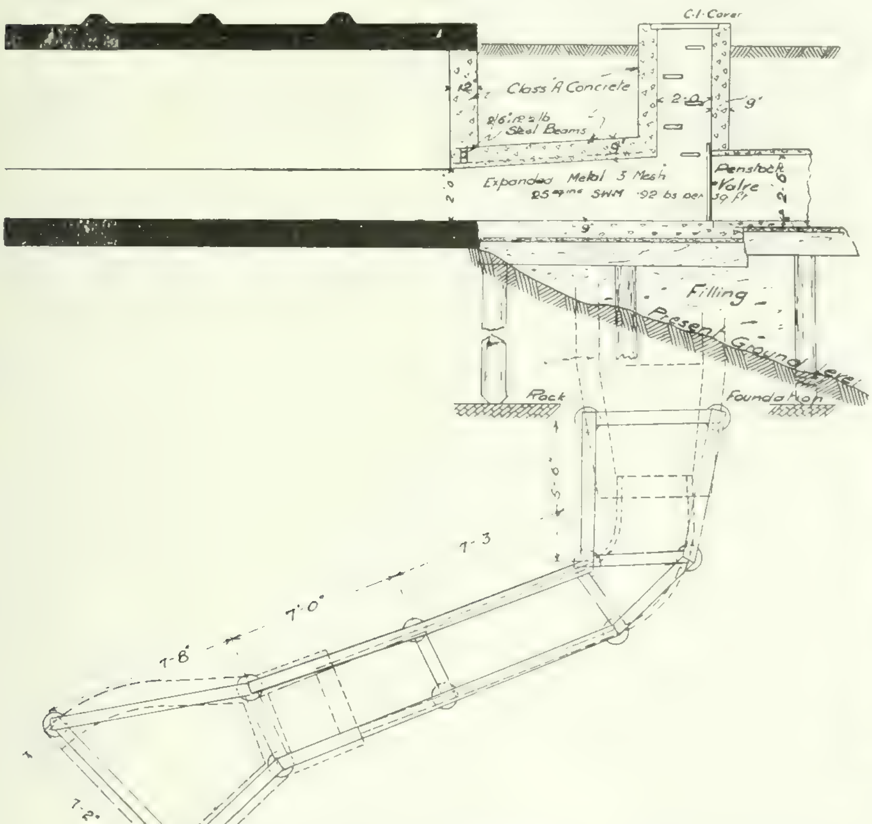

Fig. 4.—Section Through C.D. (Fig. 3), Also Plan of Piling for Supporting Connection (Lower).

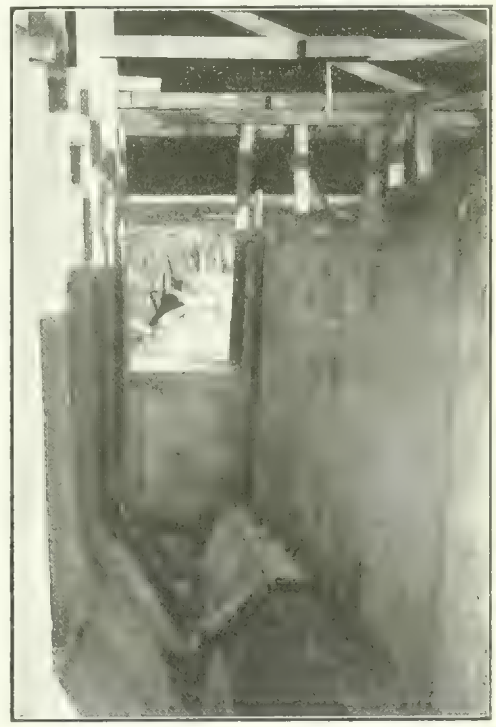

Fig. 5.—Showing Formwork and Drains; One Grit Chamber Under Construction.

the direction of sewage flow can be reversed, that is, fed from either end of the tanks, every month, or as required. By this means it is possible to equalize to a large extent the depth of deposited sludge in all 3 digestion chambers before cleansing has to be undertaken.

These tanks are in series of four, split up into 3 digestion chambers to each tank, and the sewage passes over a weir the full width of the tank, to insure a uniform flow of sewage, and thus eliminates any dead space in the upper compartment, and passes under supported by means of reinforced concrete beams having their supports on the walls, dividing the sludge digestion chambers into three. They are carried up and act as baffles to the upper compartment, which assists considerably the lighter solids to deposit on the inclined aprons, and slip down into the lower sludge digestion compartment, staying there until decomposition is complete. The cross-section shown in Fig. 9 illustrates the above features.

To minimize the passing of gases from the lower to

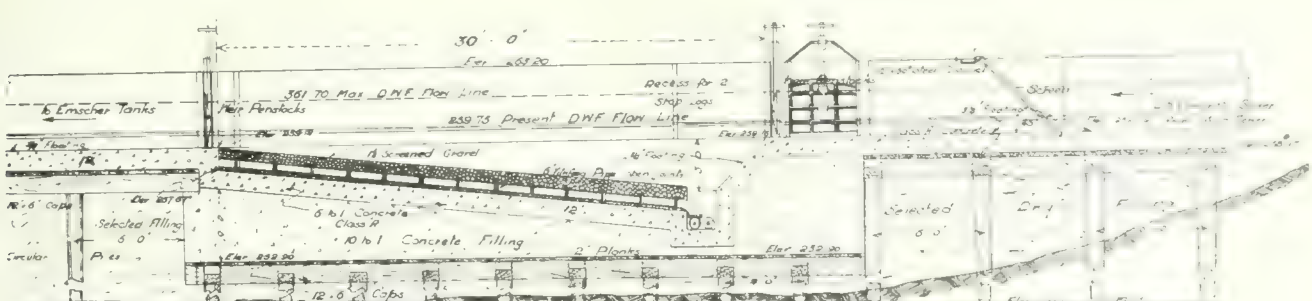

Fig. 6.—Longitudinal Section of Grit Chambers.

the upper compartment, and to adequately provide for ample ventilation for the many gases given off due to the putrefactive decomposition of the settled solids, which goes on continuously until cleansing times, these aprons were placed at a minimum space of 15-in. from the main walls, which should allow for the clogging and

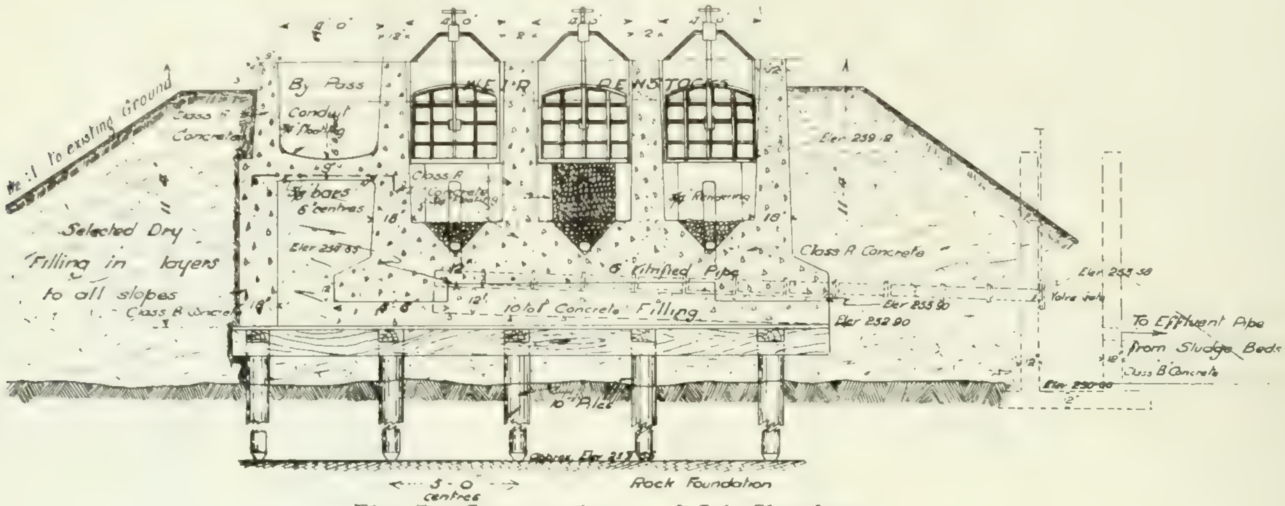

Fig. 7.—Cross-section of Grit Chambers.

scum formed. This scum would otherwise block up the smaller spaces and prevent the ventilation which is absolutely necessary for the efficient working of the two compartments.

These tanks were designed for an average velocity of 1.75 ft. per min., with a retention of 2½ hr. (assuming the hourly flow as 1/18th of the daily flow). The upper compartment is well baffled to assist the settling

Fig. 8.—Grit Chambers Under Construction—Showing Formwork, Etc., and General Method.

capacity, and all exposed surfaces are rounded off to prevent sludge deposits.

The sludge digestion chamber, owing to local conditions as to foundation, expense of construction, and efficient working depth of tanks (for better sludge results), was designed for 5 to 6 months' storage capacity. The bottom slopes to a central 3-ft. square sump at variable inclinations, the minimum being 2 ft. horizontal to 1 ft. vertical.

The sludge removal pipes are C.I., 8 in. diameter, and have an outlet connection 6 ft. below the flow line of the upper compartment. Thus on opening the gate, the sludge flows by gravity up the central vertical sludge pipe into the main C.I. pipes, laid to a minimum grade of 1 in 30 in the main divisional walls. It discharges into a small collecting well in the pump house. It is then raised by means of a low set force pump (electrically driven) into the distributing chambers feeding the different sludge beds.

The vertical 8-in. C.I. flanged sludge pipe commences at the small sump, and has a special 12-in. bellmouth casting resting on a 3-legged cast iron support; it has a clearance of at least 1 ft. all round the small sump, which affords a free entrance with ample depth to ensure a speedy removal without clogging. The operation is materially assisted by water jets from a lead pipe running entirely around the sloping sides of the digestion chamber, about one-half way up. This pipe is drilled with ⅛-in. holes at 15-in. centres. On the digestion tank being emptied, the valves regulating the sludge pipe and water service are opened, ensuring a thorough agitation of all the sludge in the digestion chamber to be emptied. In this way the chamber is efficiently cleansed, overcoming the obvious evil of the old sludge being left around the sides of tank, and the new sludge working down from the top. In the latter case the operation would clean out only a small pocket around the vertical sludge discharging pipe, and (besides leaving behind the old sludge) would considerably reduce the capacity of the digestion chamber, unless cleansed by hand labor, which owing to depth, etc., would prove a costly item.

Another important drawback is the constant clogging-up of the sludge discharging pipes, which, I think, has been remedied in a scheme whereby the horizontal C.I. pipes, connecting the vertical sludge discharge pipe with the main discharge pipes in divisional walls, are laid at a grade of 1 in 36. The main discharge pipe is also connected to the sedimentation tank by means of a valve connection, so that after each digestion chamber has been emptied, by opening the valve the pipes can be flushed out by the sewage in the upper compartment under a 6-ft. head of tank sewage. In addition to these arrangements all the extreme ends of the vertical and horizontal sludge discharging pipes (wherever possible)

are carried through the walls into inspection manholes, and fitted with a fire hose connection for cleansing purposes. Sufficient space is left for rodding, general cleansing, and inspection purposes. Manholes, carried

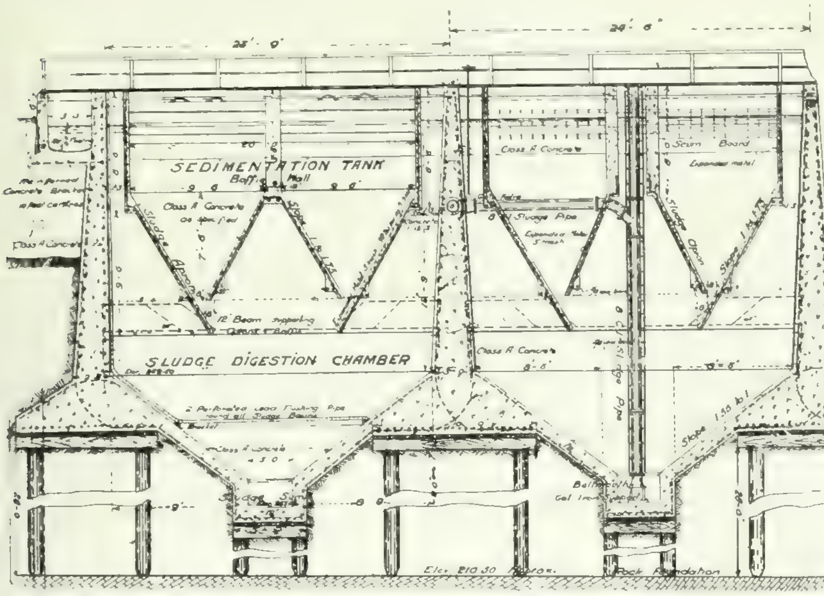

Fig. 9.—Cross-section of Sedimentation Tank (Emscher).

on reinforced concrete brackets from the baffle walls, are constructed to each tank, which are provided with W.I. built-in ladders, to facilitate the proper inspection of all parts of the tank under cleansing periods.

Sludge-Drying Beds.—The sludge-drying beds are of earthwork construction, in series of five of varying length, with a standard width of 25 ft. They are underdrained with 3-in., unjointed, vitrified pipes, laid at 6 ft. centres, and at an angle of 90° to the main 6-in. vitrified pipe. This pipe discharges into the 9-in. temporary effluent pipe, joining the main effluent discharge pipe in the manhole, as shown in Fig. 11.

At the junction of the 9-in. effluent pipe and main carrier from each bed, an open manhole is constructed, to provide for ample inspection of the water from the sludge beds, which will pass directly into the marsh.

These filters have a minimum depth of 12 in. of graded gravel, with a 1-in. layer of fine sand. Under each sludge discharging trough a concrete apron will be constructed to prevent damage to the filtration surface in times of operation.

The sludge is discharged into the different C.I. branch pipes leading to each bed by means of valves and movable wooden troughs from the distributing chambers to the beds. It is then spread over the filtration surface to a depth of approximately 1 ft., and, according to weather conditions, is spadable in 3 to 4 days without nuisance or smell.

Manholes are constructed at each branch feed pipe on the 8-in. C.I. main rising from the pump house to the sludge beds and all necessary valves. Inspection boxes are fixed for rodding and cleansing purposes.

The filtration area of these beds was calculated for 550 sq. ft. per 1,000 population, as the combined sewerage system is in vogue in the West End district.

General Construction Details.—The site purchased for the disposal works was in low-lying ground, its level being approximately 5 ft. above the level of the Bay. The geological formation consisted chiefly of stratas of very wet, blue and brown clay, intermixed with fine gravel. The 3-in. auger borings taken for guidance to the tenderers, indicated rock at 22 ft., but on excavation it was found to be a thin strata of hardpan, varying from 1 to 2 ft. thick. This discovery necessitated a complete change in the foundation plant.

The originally intended concrete piers under the walls and sumps were discarded in favor of pile foundation which, to safely withstand the load, called for 12-in. piles, 30 ft. long.

The whole of the works, owing to the low-lying nature of the site, and the difficulty of providing sufficient head to operate successfully the fixed sprays intended to be used for future filtration beds, had to be built on a trestle pile foundation in reinforced concrete.

On account of the spongy nature of the soil, together with the fact that the low elevation of the sump bottom is 14 ft. below lake level, a great amount of water had to be contended with. This rendered the excavation, setting out, pile driving and general foundation work a little more difficult to accomplish; and, as the sides of the excavation were sloped back without sheet piling or timbering of any kind, a great deal of extra excavating and filling-in had to be done owing to sides continually caving in. This, together with the

Fig. 10.—Method of Running Concrete from Mixer. Also Shows Reinforcement in Main Walls.

previously mentioned conditions, seriously retarded the quick progress of the work.

The structural walls and sumps are built of Class A concrete (4, broken stone of 2-in. gauge : 2, sand : 1, Portland cement), reinforced with ¾-in. and ⅝-in. commercial round steel rods. Expanded metal was used in the sludge aprons.

The interior concrete work of the tanks, as will be noted from the accompanying illustrations, although of a complicated nature, furnished no special engineering difficulties, except some intricate form work, which is shown in part.

The works were designed by the author as a part of an extensive scheme to solve the sewage problem for the entire city, including an east end disposal plant and main drainage system, and a storm overflow sewer to relieve the central area of the city in storm time. All these works have been designed and approved. The west end development, described above was commenced in July, 1913, and is being carried out by the city, whose tender of $63,000, not including C.I. pipes, valves, etc., was considerably lower than the next of five competitors. The work is being done by day labor.

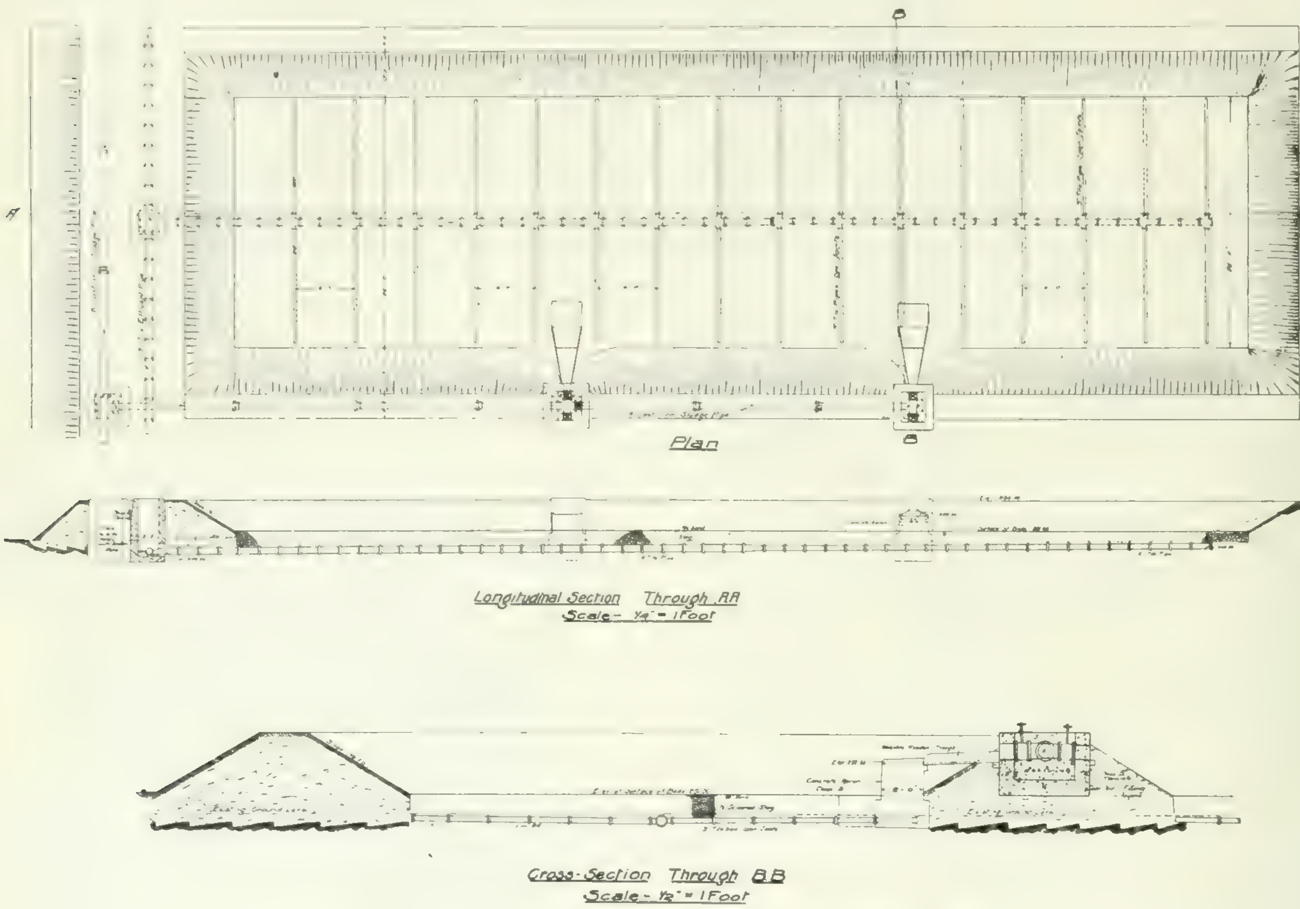

Fig. 11.—Plan and Sections of Sludge-drying Beds.

Late in the fall operations were discontinued, owing to severe weather. Construction is well under way, and should commence in the early spring.

The author has acted as engineer-in-charge, under the direction of A. F. Macallum, C.E., City Engineer.

IRON AND STEEL PRODUCTION IN ITALY.

The completed statistics of the production of iron and steel in Italy, for 1912, have been announced. The production of iron ore was 582,066 tons, which compares with 373,786 tons in 1911 and 551,259 tons in 1910. Imports of iron ore in 1912 were 18,551 tons and exports were 12,313 tons. The production of manganese ore was 2,641 tons. There was also produced 248,612 tons of iron pyrites, of which only 2,144 tons were exported, while 70,762 tons were imported.

The make of pig iron and direct castings in 1912 was 418,675 metric tons, which compares with 342,586 tons in 1911. The output of steel ingots, largely from imported pig and scrap, was 922,000 tons, a gain of 186,000 tons over 1911. The production of wrought iron from pig was only 1,500 tons, but there was a large quantity made from scrap, some of it imported material.

The total production of finished material was as follows, in metric tons:—

	1912.	1913.
Wrought iron	303,223	179,516
Steel	697,958	801,907
Total	1,001,181	981,423

The principal items of finished steel in 1912 were 392,263 tons of bars and shapes, 130,067 tons rails and 89,905 tons of plates and sheet. The output of tin plates was 28,916 tons.

In 1912, there were in operation in Italy, 64 open-hearth furnaces, two Bessemer converters, two Robert converters, five electric furnaces and two crucible furnaces.

CONTENTS OF THIS ISSUE.

ANNUAL MEETING—CANADIAN SOCIETY OF CIVIL ENGINEERS.

The twenty-eighth annual meeting of the Canadian Society of Civil Engineers will be held in Montreal, January 27th, 28th and 29th. A detailed programme appeared in last week's issue of *The Canadian Engineer*. It includes the presidential address, the election of officers and members of Council for 1914, the reception of the report of Council, the reception and discussion of the reports of the various standing committees, and the transaction of general business of the Society. A visit to the works of the St. Lawrence Bridge Company at Rockfield will form a part of the second day's proceedings. The annual dinner of the Society will be held in the Engineers' Club on Wednesday evening.

Every engineer belonging to the Society, whether to the class of member, associate member, or junior member, should be in attendance, and it remains for each to make all possible effort in that direction. Each member is a unit in the organization representing the engineering profession in Canada, and this evolves a sense of duty to exercise his initiative and influence in the unifying and strengthening the forces working among these 2,700 engineers for the betterment of his profession.

A society does not need to be of a highly specialized nature to find plenty of important and labor-requiring work for it to do. Specific problems in various engineering lines are accumulating, and the conscientious work of committees will bring even greater results and speedier solutions if the committees have behind them a willing co-operation and a desire on the part of the members of such a society to be of as much assistance as they can. Besides, each member must feel that his part should become, in early years, if it is not the case now, one of activity in the direction of the tendencies of the profession and of the representative society.

A good deal will develop in the course of the coming meeting of the Canadian Society of Civil Engineers to recompense any member for what sacrifice of time and business he may find it necessary to forego in order to spend January 27th, 28th, and 29th in Montreal.

BOUNDARY WATERS AN UNSAFE SUPPLY UNLESS TREATED.

A report laid before the International Waterways Commission last week has to deal with the sewage pollution in the boundary lakes and rivers between Canada and United States. The conditions which obtain in all localities, from Rainy River to Cornwall, with the exception of the already investigated waters in the district around Toronto, come within its scope.

It is observed that every municipality within the area investigated, on the Great Lakes and their connecting rivers, avails itself of the opportunity open to it of discharging its sewage in an untreated state into these waterways. Navigation has likewise been the cause of dangerous pollution in some localities, while the run-off from surrounding watersheds during spring floods adds materially in that season.

The results of the investigation indicate that there is not a municipality using these boundary waters as a source of supply, that is immune from danger of waterborne diseases, unless the supply is previously treated. It is claimed that the high death-rate from typhoid, along the boundary, has been directly due to 3 conditions, viz., unrestricted discharge of sewage; failure to purify the supply; and inefficiency of purification.

Although the report makes no formal recommendation, leaving that for the Commission to embody in its report to the two Governments concerned, it clearly shows the need for legislation and restrictive regulations that will require all municipalities dumping sewage, directly or indirectly, into boundary waters to previously subject it to a purification process. It also points to the advisability of a careful purification of every water supply, demonstrating that the presence of pollution for but a few days is a serious menace to public health.

CONTRACT vs. DAY LABOR IN MUNICIPAL WORK.

The engineering departments of a number of our cities have found it good policy to carry out their civic extensions, such as pavements, sewers, distributing water mains, etc., themselves. These cities have developed quite an extensive plant which enables them to carry out such work efficiently. With such plants well located and working under good organization, these improvements can be done at a figure against which contractors cannot compete, and make a reasonable profit. General construction work, however, is largely open to competitive tendering, the city engineer submitting a bid, allowing, of course, a fair margin of profit on each of his tenders. On such work, it is found that contractors are often in a position to underbid the city engineering department, sometimes to the extent of 25%. With properly qualified and adequately paid inspectors, such work is done better and cheaper than the municipality could do it. Besides, the city engineer, already overburdened, is not carrying the additional responsibility and is enabled to better superintend the details of construction of the work which his department is doing. This is largely owing to the fact that the average city cannot keep up an organization to the same efficiency as a contractor's organization. It is not sufficiently elastic to handle the variation in quantity of work which develops in a growing city of any size. Again, a city finds itself handicapped in obtaining and retaining the most efficient foremen and laboring men. Our cities are subjected to a climate that curtails civic work in winter, and foremen cannot be given work the year round. This gives the wide-awake contractor an opportunity to secure the good foremen from the city forces, and to retain them by paying them better than the average city engineer is permitted to do. Generally speaking, our cities pay the lowest wages, resulting in more expensive and less satisfactory work.

It would appear that our cities are materially benefitted by subjecting all their work to competitive tendering. Notwithstanding the fact that the city engineering department generally secures those improvement works for which it is specially adapted, the competition gives the contractors their chance of tendering, thereby removing an important stumbling block that public opinion frequently finds in the foreground of the civic administration. It also adds a certain stimulus to the city engineering staff that is important. Otherwise the city, because of the fact that low wages are paid, builds up a laboring force of a class of men to which few other employers would give work for the simple reason that they are not worth what they have to be paid. Such men, regularly employed by a city, get an idea in time that the city is bound to provide work for them. The constant stimulant afforded by the competition of tendering, prevents such deterioration of organization. This prevents the involved increase in the cost of work. It also establishes a formidable reason for the employment of the best men, paid accordingly.

TORONTO WATERWORKS EXTENSIONS—THE OLD REPORT AND THE NEW.

The question of water supply gets little rest in the City of Toronto. For years civic authorities have studied over it unceasingly, and the citizen has frequently had cause to assume a share of the worry when his business or his household was jeopardized by uncertainty or unsuitability of supply.

Our readers will remember the 1912 report of a Board of Water Commissioners, which recommended as a solution to the problem, the installation at Scarborough Heights of an intake, tunnel, filtration plant, and reservoir, with gravity feed mains to the city. The proposal evoked an editorial discussion in these columns prior to the submission of a by-law to authorize the necessary expenditure. This discussion included many criticisms, chief among which being:—

(1) That, since Lake Ontario water as a Toronto supply must necessarily undergo filtration before use, the quality of the water off Scarborough did not justify the heavy expenditure involved in bringing it 12 miles to the centre of the city, or in serving West Toronto from such a distant source.

(2) That pumping the supply to a height of 370 feet into a reservoir on the Scarborough plateau was unnecessary, and meant greater cost of construction and a heavier continuous cost of operation, a considerable percentage of the head thus acquired being lost in the gravity flow mains to the city.

(3) That to guard against interruption of electrical operation of pumping station by using an independent electrical supply, preferably from the Trent Valley or some other source, to supplement Niagara power, was not adequate provision. The difficulties of electrical supply being mainly those of transmission, a storm which would cause interrruption of service on the Niagara line would probably have a similar effect on any other long transmission line.

(4) That the recommendation to duplicate the slow sand filtration plant on the Island was not warranted by its performance, and that the proposal of a mechanical filter at Scarborough and a slow sand filter at Toronto Island to treat water of practically the same quality was anomalous.

(5) That the estimated cost, $5,320,000, was much too low, to carry out the work proposed.

The Canadian Engineer strongly voiced its belief that the Scarborough scheme was not an adequate return for the amount of money which the citizens of Toronto would be asked to spend, as it did not assure an abundant supply of pure water at the lowest possible cost.

With the report open to such criticisms as these, the by-law which was submitted to the ratepayers on Jan. 1st, 1913, did not specify the nature of the waterworks extension. It read: "for additions and extensions to the waterworks pumping and distributing plant." It carried, authorizing an expenditure of $6,677,000. Unsatisfied with the report, the city proceeded forthwith to investigate the whole problem for itself, and the new report is the outcome.

It is interesting to read the criticisms of the old report that are embodied in the new.

REPORT ON PROPOSED EXTENSIONS OF TORONTO'S WATERWORKS SYSTEM

EXTRACTS FROM REPORT RECOMMENDING A 60,000,000 GALLON PER DAY ADDITION OF MECHANICALLY FILTERED STEAM PUMPED WATER SUPPLY FROM AN INTAKE IN 49 FEET OF WATER ONE MILE OFF VICTORIA PARK—ESTIMATED COST $6,033,700

A REPORT, prepared by the Department of Works of the City of Toronto, and dealing with the proposed extension of the waterworks pumping and distributing plant, is presented herewith in extracted and summarized form. Its chief features are: A forceful condemnation of the Scarborough scheme as recommended in the 1912 report of the Commission appointed by the city in 1911 to investigate the problem; and a proposal covering the installation of a plant at Victoria Park to filter and pump directly into the mains water drawn through a 9-ft. tunnel 2 miles in length from a 110-ft. intake crib in 49 feet of water.

The previous report (extracted in *The Canadian Engineer*, May 30th, 1912) was met with the following summary of essentially questionable features:—

1. The basic information essential to the proper, economical and serviceable design of such a system was not procured.

2. The location, aside from the impossible hydraulic conditions it creates, considered in conjunction with our present pumping system, was ill chosen, and altogether too far east of any probable future centre of distribution.

3. The intake crib proposed, at an estimated cost of $500,000, to be located in 100 feet of water, does not follow proved practice, and is too costly an experiment.

4. A tunnel two miles long, driven to a point where a depth of 100 feet of water is obtained, is unnecessarily long, and no essential purpose is served in procuring such depth of water. The estimate for the tunnel is low.

The depth at which it was proposed to drive the tunnel was so great that if resort to compressed air working became necessary, the tunnel would have to be abandoned.

5. The proposal to install electric pumps without steam reserve, is imprudent.

6. The proposition to pump the whole water supply to a height of 370 feet, when 75% of it need only be

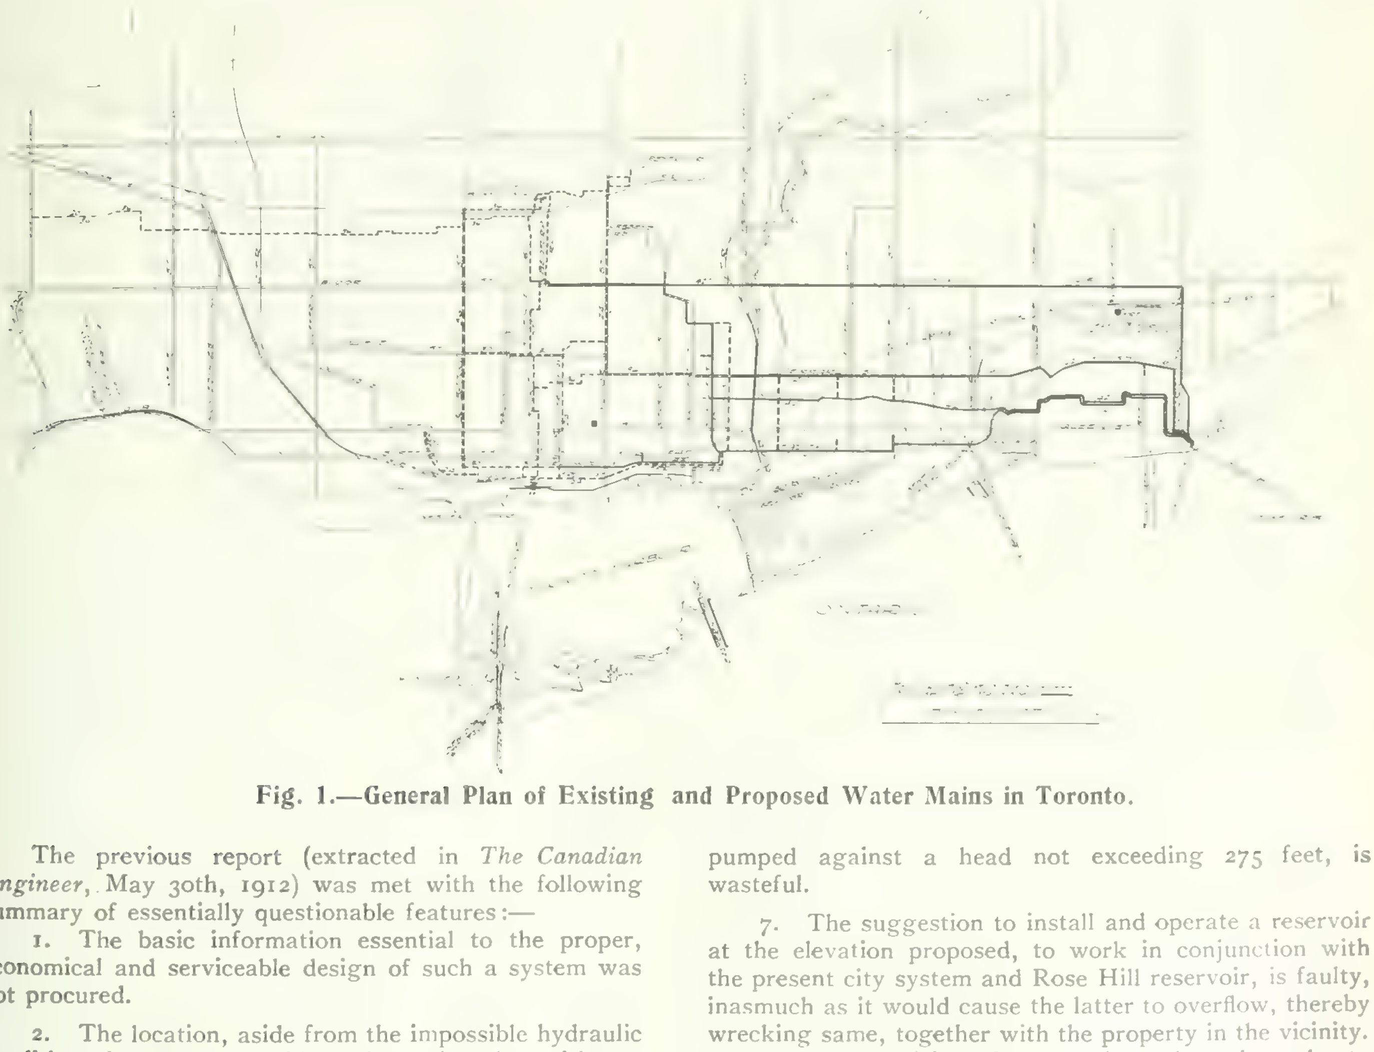

Fig. 1.—General Plan of Existing and Proposed Water Mains in Toronto.

pumped against a head not exceeding 275 feet, is wasteful.

7. The suggestion to install and operate a reservoir at the elevation proposed, to work in conjunction with the present city system and Rose Hill reservoir, is faulty, inasmuch as it would cause the latter to overflow, thereby wrecking same, together with the property in the vicinity.

8. The provision of one steel supply main, only, to the city, is unwise, as in case of breakdown outside the city limits, there would be an entire cessation of supply.

9. The hydraulics of the problem were evidently not carefully considered, and their effect upon the existing system realized, inasmuch as the pressure developed

would render the John Street station, tunnel, filtration plant and intakes useless, unless the aforesaid station was equipped with new machinery, capable of operating against the pressures developed by gravity.

10. The booster stations suggested are unnecessary.

The Proposed Works at Victoria Park.

In the new report, it is proposed to build an intake crib off Victoria Park, 5,100 ft. from shore, in 49 ft. of water. The crib will be approximately 110 ft. in diam., constructed of steel and concrete, and surmounted by a house, the main part of the crib rising 19½ ft. above the lake. The crib will contain the necessary ports for the admission of water.

The inside of the crib will contain a vertical steel shaft, lined with cement or brickwork, running down to a proper depth below lake level, so as to connect with a tunnel 6,380 ft. long, running horizontally to the shore at Victoria Park. The internal diam. of the shaft will be 11 ft., that of the tunnel 9 ft., the latter to have its invert 105 ft. below mean lake level. At the shore, there will be a vertical shaft 10 ft. in diam., rising above the normal lake level at this point. From the vertical shore shaft there will be 2 horizontal 7-ft. tunnels, one on each side and parallel with the shore. One of these tunnels will supply the suction side of the pumps in the station to be erected, the other will act as a reserve to be used in case the size of the station is increased later.

1. A system which will supply an additional quantity of water equal to that now being used during maximum draft, thus practically duplicating the present plant. Therefore, in the event of accident at any time to the sewage purification plant, or either filtration or pumping plants, the use of either plant could be discontinued, and the safety of the supply still maintained. By reason of the proposed plant being a duplicate in capacity of the existing plant, with provision for future increase, the continuity of the supply is assured.

2. A system which will operate in exact harmony with the existing plant, thus enabling both to work in conjunction.

3. An arrangement which can be doubled in capacity without doing unnecessary work.

4. A supply which is unfailing, in so far as human agency can make it. It will not be deleteriously affected by storms, ice, shifting sand, etc.

5. A supply of water, which is as pure as it is possible to obtain in the vicinity of Toronto, and which after treatment will be perfectly safe and satisfactory.

6. An improved service throughout the entire city.

7. An attractive park on the waterfront.

Intake Crib.

The intake crib is in a sense the most important, and, in some ways, the most difficult part of the work. On account of the nature of the elements to which it is exposed, the design should be worked out from the experience of others. Cribs

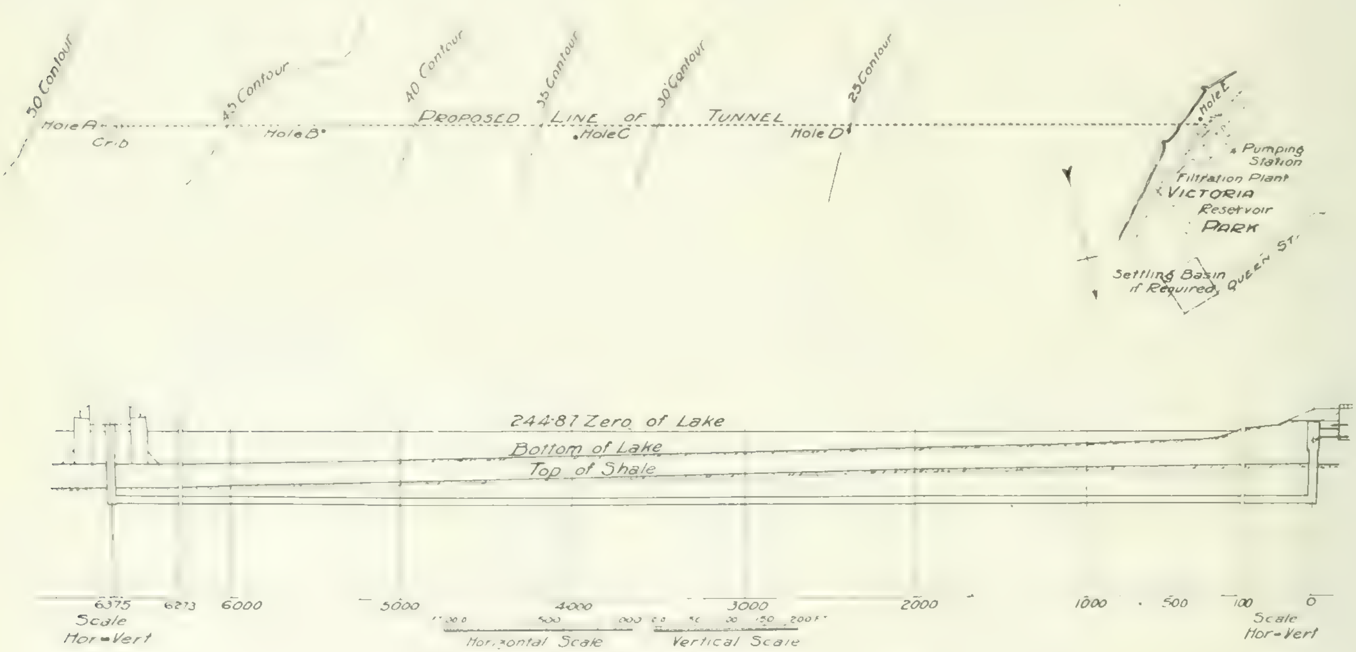

Fig. 2.—Plan and Profile of Proposed Tunnel.

The pumping station will be located in Victoria Park, which, with a piece of land to the east, is of sufficient size to contain a station and filtration plant of a capacity of 120 million Imp. gal. per 24 hr., should such capacity ever be required.

The pumping station will have a capacity of 60 million Imp. gal. per 24 hr., but is being so designed that this may very easily be increased to 120 million gal. if desired. Since the water will have to be filtered, the station must be divided into 2 parts, viz., low-lift and high-lift, the former taking the water from the tunnel shaft and delivering directly to the filters, while the latter will deliver the filtered water direct to the city mains. Each part will have a capacity of 60 million Imp. gal. The low-lift pumps will work against a head of approximately 75 ft., while the approximate head on 3 of the high-lift pumps will be 220 ft., or 95 lbs. per sq. in., and that on the fourth pump about 315 ft., or 137 lbs. per sq. in. The exact pressures against which the low-lift pumps will have to work cannot be determined until the make of filters is known.

The mechanical type of filter is recommended, and in connection with this it is proposed to install a reservoir with a capacity of 2½ million Imp. gal., and to provide space for a settling basin should the make of filter require it.

From the station, four 36-in. pipes will deliver water to four new 42-in. mains which join the present distribution system.

In short, the plan contemplates:

have been constructed in the lakes by various other cities; at Buffalo the crib is 110 ft. diam. in 18 ft. of water; the Cleveland crib is nearly 5 mi. from shore in 49 ft. of water, and is 100 ft. in diam. Chicago has 6 cribs of varied construction, some with surrounding breakwaters, and the latest designed without. Of the latter, the Harrison crib is 112 ft. in diam. and is in 34 ft. of water, while the new Dunne crib is 111 ft. in diam. and in 33 ft. of water. The Milwaukee crib is under 60 ft. in diam. and is in 25 ft. of water, but from a study of conditions, it appears to be inadvisable to adopt so small a size.

From a study of the experience of these cities, it is concluded that the Toronto crib should be 110 ft. diam.

The depth of water in which the crib can be set depends upon the method of placing it, and the forces to which it will therefore be subjected. This crib, made of a steel shell, will be constructed in the harbor and floated to the desired location and sunk. On account of the depth of water in the bay, the shell could not be floated to a greater depth there than 17 ft. It is clear that the success of such an undertaking will depend, to a very large extent, upon the relative amounts of the shell above and below the water surface when floating, and as the depth below is, in this case, small, the total height of the structure is limited. So far as is known, no city in America has installed a crib under such conditions as those existing at Toronto, in water deeper than 50 ft., the Cleveland intake being the deepest. Since the cost of this part of the work will be

great, and hence any unsuccessful experiment would be very serious, it is not advisable to attempt anything that has not been done successfully elsewhere, so that the depth of water in which this crib will be placed is 49 ft. The water entering such a crib will be quite as good for drinking purposes as if taken at much greater depth.

The intake crib will consist of two concentric steel cylinders, set on end and firmly braced together, so as to be rigid and stiff, the outer cylinder being 110 ft. diam., and the inner 60 ft. diam. Plates set radially between these shells will divide the annular space into compartments, which will be constructed with bottoms so as to make them watertight. The compartments will then be sufficiently filled with concrete to make the draft of the structure 17 ft., after which it will be towed into the desired position and sunk, the lake bottom having been previously levelled and otherwise prepared for its support. After sinking, the annular space will be filled with concrete, and the structure built up above the water to provide living quarters for men, with lights and signals for mariners.

Properly constructed ports in the crib will admit water to the inner 60-ft. well. These ports will be controlled by gates which may be closed at pleasure, but the water will never be pumped from the inside of this well. An arrangement has been provided, however, so that it will be quite possible at any time to pump all of the water out of the tunnel for cleaning or other purposes, should this be desired.

Intake Shaft.

Through the centre of the intake crib, a vertical steel shell will be sunk to a depth to meet the tunnel. This shell will rise inside the crib above lake level, and will have proper openings for the admission of water to its interior; these ports to have gates that may be closed when desired. The material will be excavated from the inside of this shaft, which will be lined with brickwork to finish 11 ft. inside diam.

Tunnel.

A tunnel will be driven between the shore and intake shaft, having an inside diam. of 9 ft. with a brick or concrete lining. As it is possible that compressed air will be necessary in the driving of this tunnel, and in order to make it perfectly safe for workmen, the invert will be not over 105 ft. below the lake level. The length of the tunnel will be about 6,380 ft.

Shore Shaft.

This shaft will be of similar dimensions to that at the intake, but with a diam. of 10 ft. inside the brick or concrete lining. It will be closed at the top, and at 13½ ft. below zero lake level will have two 7-ft. diam. horizontal branches, to which the suction pipes of the pumps will be directly connected. The cover on the shore shaft will be quite high enough to prevent damage from surges in the tunnel, these being very small, owing to the low tunnel velocity of only 1.71 ft. per sec. when delivering 60 million Imp. gal. per 24 hr.

Capacity of Tunnel and Shafts.

With a draft of 100 million Imp. gal. per 24 hr. the loss of head in the tunnel and shafts will be under 2.5 ft., so that the capacity will be much above 100 million gal. if it is desired to increase the demand above this amount at any time.

Low-Lift Station.

The purpose of the pumps in this station is to take water from the tunnel shaft and deliver it to the filters. They will be driven by steam and have a total capacity of 60 million Imp. gal. per 24 hr. The lift at zero lake level may be approximately 75 ft., depending upon the make of filters used. In order to procure the best use of the tunnel, the floor of this station should be at lake level. An excavation will be made and the station built with watertight walls and basement. In order to insure safety, there will be two 48-in. delivery pipes to the filter plant, each conduit carrying away the water from two pumps.

High-Lift Station.

This station will also contain steam-driven pumps, having total capacity of 60 million Imp. gal. per day, three having a total lift of approximately 220 ft., and the fourth with a lift of about 315 ft. The precise lift is yet to be determined. The floor level of this station will be at the ground level of Victoria Park.

Filtered water will be delivered to this station through a single 7-ft. pipe, the suction of each pumping unit being connected directly thereto. There will be 4 separate discharge pipes, each 36 in. in diam., one from each pump, and connected to the distribution system.

Boiler Room, Coal, Storage, etc.

The boiler room will be located between the engine rooms. This arrangement brings the boilers close to all pumps, thus giving good steam connections, and also precludes any interference whatever between the boiler and engine foundations and the water pipes. This latter matter is of the very greatest importance. Much attention has been given to the security of the system, and the prevention of damage to the pipes from any cause. It is essential that they must always be easily accessible for examination and repairs.

The boilers will be equipped with mechanical stokers, and the boiler room will be furnished with coal and ash handling machinery, so as to reduce the cost of operating the plant to a minimum.

Coal will be conveyed to the plant in railroad cars drawn by electric motor, along tracks laid to York Station, a distance of 1½ miles.

The coal bunkers will have a storage capacity equivalent to one week's supply.

Reservoir.

The matter of an additional reservoir is one requiring careful study. There is no convenient location for a reservoir in the eastern part of the city, and it would have to be located far beyond the city limits if placed in this direction.

An additional reservoir for the city of Toronto is by no means essential, and not at all requisite. It is desirable that there should be some water storage to provide for fluctuations in demand from time to time. This storage has already been adequately provided for in the Rose Hill reservoir, which has ample capacity for all the present and proposed pumping equipment, and will readily suffice for the needs of Toronto for some time to come.

Since a proposition has been made to establish a second reservoir in connection with plans of the Commission of 1912, it may be well to point out, that if a second reservoir were to be used on the same supply mains as the present Rose Hill reservoir, then the new reservoir would have to be placed on exactly the same level as that at Rose Hill. If the new one were the higher, as proposed by the Commission, the present reservoir would be flooded.

An examination of the country has shown that to secure suitable land for such a reservoir, it would be necessary to go so far out that much of its effect would be lost. Such a plan cannot be recommended.

The present Rose Hill reservoir has a capacity of 39¼ million Imp. gal., which corresponds to about 20 hrs.' supply at the present average daily pumpage of approximately 50 million Imp. gal., and is quite sufficient to compensate the ordinary fluctuations of discharge, due to fires, excessive heat or cold, and other causes.

It will be interesting in this connection, to give the experience of some of the larger American cities using lake water. Buffalo, with an average daily consumption of 117 million Imp. gal., has a single reservoir holding 98 million gal. or 20 hrs.' supply. Detroit, with an average daily consumption of nearly 88 million Imp. gal., has no reservoir. Chicago does not possess a reservoir. In Cleveland, the average daily consumption is 63 million Imp. gal., and the city is divided up into 3 districts for distribution purposes, there being a reservoir for each district, the largest having a capacity of 67 million Imp. gal. Milwaukee has a present consumption of about 79 million Imp. gal., and is now increasing its pumping capacity, but there is no intention of increasing the capacity of the reservoir, which holds only 17 million Imp. gal., or about 6 hrs.' supply.

The foregoing examples show that Toronto has now a much larger reservoir capacity than many other of the larger cities, the size of reservoirs being evidently largely influenced by local conditions. The experience of the cities quoted, confirms the conclusion otherwise reached, that there is no necessity at present to increase the reservoir capacity for this city.

Distribution System.

From the pump house there will be four 36-in. pipes, with Venturi meters, running a short distance from the station, after which they will be enlarged for distribution purposes, and will feed four 42-in. mains, all of these pipes being cross-connected and controlled by valves in such a way as to make a perfectly flexible arrangement. These four mains will then run across Queen St., their locations being approximately as follows (see Fig. 1):

1. One 42-in. main will run across Queen St., up Victoria Park Ave. to Danforth Ave., along Danforth Ave., over the new Bloor St. viaduct to Bloor St., and along Bloor St. to St. George St. At the corner of Bedford Rd. this main will be cross-connected to the present 36-in. main., valves being provided so that the connection may be closed as desired. For the present this main will be placed on the service of the middle district, and hence the connection at Bedford Rd. will be closed, but should it be desirable to serve the [illegible] district, this valve would be opened, and all connections with the middle district closed.

This main will be used on the middle district, and will, therefore, be connected to the 12-in. main at Coxwell Ave., to

the [illegible] in. main at Broadview Ave., and to a new main included in this project at Sherbourne St. It will also be connected with the 16-in. main on St. George St. All of these connections will have valves.

The discharge pressure on the pumps at the High Level Station supplying the middle district is 65 lbs. per sq. in., and hence, after making allowance for friction and difference of level, the pressure at the Victoria Park Station on the pump supplying the above 42-in. main will be approximately 137 lbs. per sq. in. While this pressure is higher than usual, yet the pipe rises rapidly after leaving the station, and there will be only about 2,000 ft. of it subjected to a pressure of over 100 lbs.

2. The second 42-in. main will run from the park across two lots to Kingswood Ave., then up Kingswood Ave. to Kingston Rd. to Heyworth Cres. to Woodbine Ave., across two lots to Patricia Rd. and through two lots to Small St., to Gerrard St., and then along Gerrard to Sackville St. This main will connect with the 12-in. main on Beach Ave., the 12-in. main on Leslie St., the 12-in. main on Carlaw Ave., the 12-in. main on Broadview, the 24-in. main on Sumach St., and the proposed 42-in. main on Sackville St.

the 12-in. main at Sherbourne St., the 12-in. main at Jarvis St., the 12-in. main on Yonge St., and the 24-in. and 36-in. mains on Simcoe St.

5. In order to make this system most effective, a new 42-in. main will be laid up Sackville St. from the corner of Eastern Ave. and Cherry St. to Wellesley St., thence along Wellesley St. to Parliament St. or Rose Ave., to Howard St., to Sherbourne St., to Bloor St. This main will connect with the proposed new 42-in. main at Cherry St., Wilton Ave., Gerrard St. and Bloor St., but at the latter point there will be a closed valve normally, as the Bloor Street main will work on the middle district. It will also connect with the present system at the 12-in. main on Queen St., the 12-in. main on Wilton Ave., the 36-in. main on Gerrard St., the 12-in. main on Carlton St., and the 12-in. main on Wellesley St.

A study of Fig. 1, showing these mains, and their connections to the present system, will make it perfectly obvious, that this distribution plan will give ample accommodation for the water from the new station to reach all points of the city, and will enable the new station to work in perfect harmony with the present plant.

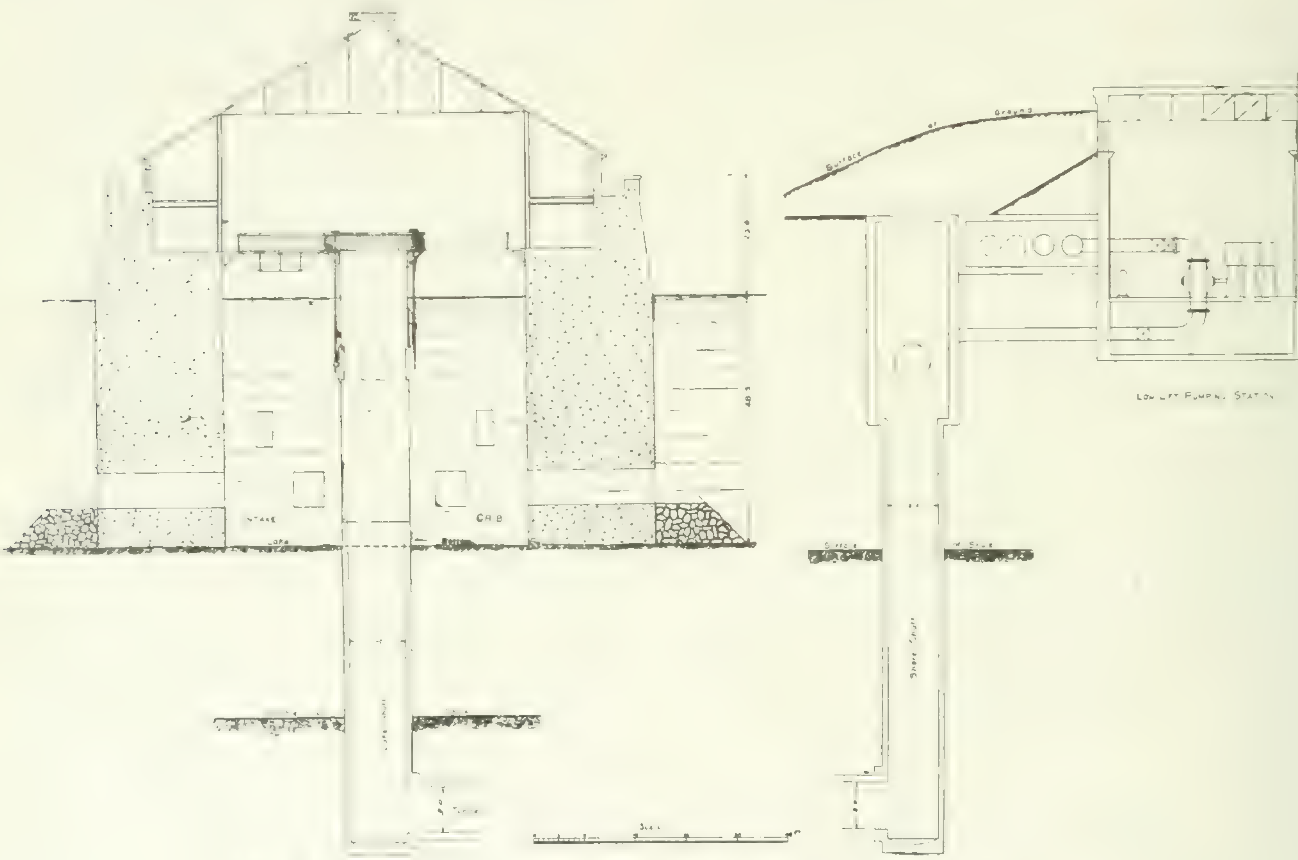

Fig. 3.—Section of Proposed Intake Crib, Lake and Shore Shafts.

3. The third 42-in. main will run from the park across the lots mentioned south of Queen St. to Scarborough Rd., north to Pine Ave., to Balsam, to Pine Cres., to extension of Williamson Rd. to Lee Ave. It will then run north on Lee Ave. to the proposed extension of Norway Pl., along Norway Pl. to Woodbine Ave. to Dixon St., across Kingston Rd. to Edgewood, to Hemlock, to Maughan Cres., to Ashbridge, to Applegrove, to Wilton Ave. extension, and along Wilton Ave. to Sackville St. This main will connect with the 12-in. main on Coxwell Ave., the 12-in. main on Leslie St., the 12-in. main on Carlaw Ave., the 12-in. main on Broadview Ave., the 24-in. main on Sumach St., and the proposed 42-in. main on Sackville St.

4. The fourth 42-in. main will run along the same streets as the third, to Maughan Cres. It will then run south to Orchard Park Rd., across Queen St., through a corner of the Ontario Jockey Club grounds to Eastern Ave., and along this street to Cherry St., thence to Front St., to Wellington St., to Simcoe St. This main will connect with the 12-in. main on Kingston Rd., the 12-in. main on Leslie St., the 12-in. main on Carlaw Ave., the 12-in. main on Broadview Ave., the 24-in. main on Sumach St., the proposed 42-in. main at Sackville St.,

An examination of the report of the Commission indicates that they contemplated only one supply main, and that through the northern section of the city a considerable distance removed from the point at which maximum consumption occurs. Therefore, even if their scheme were workable, it would be necessary for the municipality still to spend upwards of $2,000,000 upon a distribution scheme within the city limits, and $250,000 for additions and steam reserve at the high level pumping station.

In this project, in addition to the supply feature, provision is made for 32 miles of large distributing mains, at a cost of approximately $2,393,000. This will provide an almost ideal system of distribution, covering the needs of the city for many years to come.

Estimated Cost of Project as Recommended.

Lake crib complete and placed...	$ 400,000 00
Lake shaft, tunnel, and shore shaft...........	800,000 00
Site and buildings	500,000 00
Pumping equipment	380,000 00
Boilers and stokers	80,000 00
Coal and ash handling machinery............	30,000 00

Tracks and overhead equipment from York to pumping station	35,000 00
Motor and equipment for handling cars	5,000 00
Electric lighting unit at station	2,000 00
Twenty-six miles of distribution mains	2,040,000 00
Specials and valves	60,000 00
Filtration plant	600,000 00
Levelling, grading, etc.	5,000 00
	$4,937,000 00
Add 10% for engineering and contingencies	493,700 00
	$5,430,700 00
Six miles of distribution main—High Level pumping station to West Toronto, for part of which contracts have been awarded	353,000 00
Additions to High Level pumping station, and provision of steam reserve sufficient for ultimate output of this station, for part of which contracts have been awarded	250,000 00
Total	$6,033,700 00

Recapitulation.

Expenditure authorized by ratepayers (January 1st, 1913)	$6,677,000 00
Estimated cost of project as proposed	6,033,700 00
Balance to meet debenture discount and financing	$ 643,300 00

Outstanding Features of the Report.—Claiming that Lake Ontario is the only natural source of water supply for Toronto, the report passes the following observations upon the 3 possible locations for the new installation, which are:—

1. At Toronto Island adjacent to the present system.

2. At some point west of the present works, e.g., west of Humber Bay.

3. At some point east of the Island, which would mean at least as far east as the Woodbine.

The Island Location.—Site: Bed of lake slopes gradually for 1,700 ft. from shore to depth of 23 ft.; then falls with grade of over 10%, making problem of construction of intake difficult and uncertain.

Reliability: Essential that extension be placed at some distance from present system, else the same local cause might readily affect both.

Purity: Quite possible to treat present supply so as to make it perfectly safe and very desirable.

Distribution: Rapid expansion of city demands additional distribution centres conveniently situated for economy. Distribution from single source imprudent.

Western Location.—Site: Not fully investigated.

Reliability: No definite opinion advanced. Indications favorable.

Purity: Water around Humber Bay and to the west, polluted.

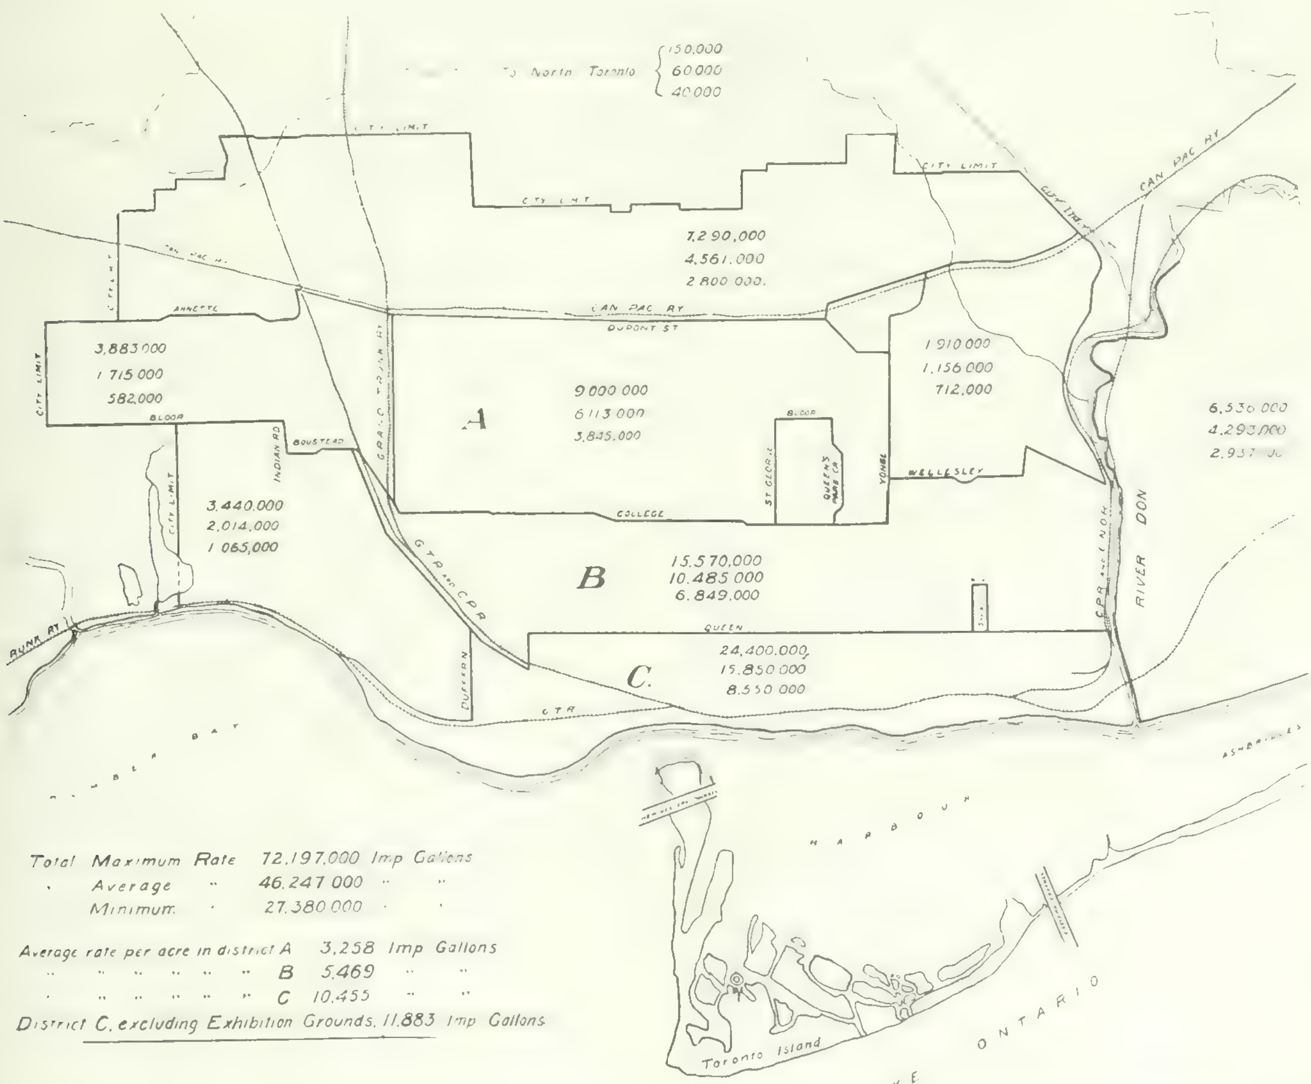

Fig. 4.—Maximum, Average and Minimum Daily Water Consumption of Toronto, as Determined by Pitometer Survey.

Distribution: Serious objection, in that heavy piping expenditure would be entailed.

Eastern Location.—Site: Effluent from Morley Ave. sewage disposal plant necessitates a location to the east. No advantage in site east of Victoria Park.

Reliability: Borings indicate feasibility of driving tunnel in good shale at favorable depth; also splendid location for intake. (See Fig. 2). Victoria Park "an almost ideal location."

Purity: Water from a point one mile from shore (2½ miles from Morley Ave. outlet) and 40 ft. below lake level, quite satisfactory, with after treatment; and fully as desirable as that taken from further east. Vastly superior to the present supply as regards turbidity.

Distribution: Admirable position for connection to present system. Distribution begins immediately upon leaving plant.

The report supports the choice of Victoria Park as the site for the proposed plant on the ground that it is most favorable from a distribution standpoint. The extensions can work in harmony with the present John St. station, constituting as well a duplication to serve the entire city in the event of interruption of the present plant. As the city expands eastward it will be logically situated for distribution. The supply there is comparable in quality with that of Scarboro' Heights, and 4½ miles nearer the city. The lake bottom is admirably suited for tunnelling and a crib may be conveniently located at a reasonable depth. A bar or ledge about a mile wide runs out from shore on an easy gradient, and at one mile out has reached a depth of 50 ft. Borings revealed suitable shale at this point 82 ft. below the lake level, this formation extending to the shore on a grade approximately paralleling lake bottom.

Pitometer Survey.—An interesting feature of the report is the result of an investigation by pitometer survey into the city consumption, as indicated in Fig. 4. The area of Toronto, excluding the Island, Harbor, Ashbridge's marsh lands, Humber Bay, and that portion of the Lake west of the Island, within the city limits, approximates 29.6 sq. mi., or 18,949 acres. From the plan the average consumption per day over this section of the city, within the period covered by the compilation, averaged 46,247,000 Imp. gal. An examination shows that in Districts "B" and "C" the average daily consumption amounts to 26,335,000 Imp. gal., or 56.9% of the total water supplied, or, in other words, 56.9% of the total water supplied per day, is consumed in 3,433.19 acres, which constitutes 18.1 per cent. of the entire acreage of the city. These figures show that the maximum usage is in the business and manufacturing section of the city, and that special distribution service must be provided in order to convey the requisite quantity of water at adequate pressure to the maximum user.

RAILWAY EXTENSION IN SOUTH AFRICA.

Amongst the larger projects which the South African Railway administration has on hand at the present time is an important deviation of the existing line between Maritzburg and Rietspruit, about 70 miles from Johannesburg on the main line from Durban. This alteration, which is known as the Town-hill deviation, has been contemplated for many years, its object being to reduce the heaviest gradient on the line, which is as much as 1 in 30. It will extend to about 12 miles in a country which is exceptionally heavy, and the work is so great that the department has decided to divide it up into several sections.

STEEL HARDENING AND TEMPERING.

THE hardening of steel has been thoroughly studied by metallurgists, who have given a great deal of time and thought to their investigations with a view to establish a satisfactory theory to account for this very marked phenomenon in connection with steel. The theories brought forth are both numerous and varied. Mr. R. B. Hodgson, of the Crooks-Roberts Company, Sheffield, recently read a paper before a meeting of the Institute of Mechanical Engineers of Great Britain, containing some interesting and practical notes on the hardening process. The following is abstracted from his paper:

In connection with the heat treatment of steel, microscopical evidence has proved most valuable, and it is believed that if two samples of carbon steel selected from two different and distinct sources, but each giving approximately the same chemical analysis, be prepared for microscopical examination under normal conditions, their appearance will be practically the same.

In reviewing carbon steel we find that an increase in the percentage of carbon is attended with increased hardness. In these days, however, we cannot base the definition of steel entirely on the peculiarity due to carbon, since there are other elements that can confer hardness to the iron. Iron readily alloys with different metals, such as aluminium, chromium, molybdenum, manganese, nickel, palladium, platinum, thodium, titanium, tungsten, uranium, vanadium, and many very important and remarkable results are obtained from the resulting alloys. The only metals that we need consider for our purpose are chromium, manganese, and tungsten since alloy steels containing these three metals lend themselves to, and are particularly suitable for cutting tools, which have to deal with work under conditions such that require the tool to be not only harder than can be expected in the case of ordinary carbon steels, but also capable of greater endurance under the two special circumstances of modern increased speeds, or to deal with the machining of very hard materials.

Chromium is used extensively in the production of special steels, as armourplates, axles, projectiles, and tool steels. The chrome iron-ores as found in either Asia Minor, Bohemia, France, Norway, North America, Silesia, and Shetland Isles, are the sources from which the alloy of iron with chromium is obtained. Ferro-chromium is prepared as a commercial article in a variety of grades, having different percentages of carbon and chromium. A grade specially valuable and used in the manufacture of high-class tool steel is 0.5 to 1 per cent. carbon, and 65 to 70 per cent. chromium. In the finished tool steel, such as very hard turning tools, the quantity of chromium varies between 2 and 3 per cent.

All steel contains some manganese, although the narrow limits of its contents, 0.2 to 1 per cent., as usually present in ordinary finished commercial carbon steels, does not materially influence the properties of the steel. Manganese frequently occurs in iron-ores and is partially reduced along with the iron, 5 to 20 per cent. Manganese will result in the production of a white pig-iron in a highly crystalline condition, containing a large amount of carbon in chemical combination, this is called "spiegeleisen," on account of the beautiful bright appearance of its crystalline plates, a condition which disappears if the manganese is increased above 20 per cent.

An alloy used extensively in steel making is that known as ferro-manganese, containing from 75 to 87 per

cent. manganese alloyed with steel. Manganese produces a material that is hard, tough, strong, and non-magnetic, and gives varying results according to the percentage. If 1 to 3 per cent. manganese be present the steel is brittle and unworkable, and up to 7.5 per cent. the steel may be likened to glass for brittleness, and beyond 7.5 per cent. the extreme hardness begins to disappear, but all manganese alloys possess extraordinary qualities of hardness combined with toughness, such as do not occur in the case of any other alloy. Manganese steels are so hard that they cannot be machined, but may be forged into various shapes as easily as very mild steel, and the ordinary process of quenching in water toughens but does not harden manganese steel. Sudden quenching at a high heat will improve the tensile strength and elongation.

Tungsten is chiefly prepared from wolframore, and the metal readily alloys with iron to form ferro-tungsten. When alloyed with carbon steels tungsten plays an important part in helping to confer great hardness upon the steel, but in the absence of carbon, the presence of tungsten will have very small influence on the physical properties of the steel. Further, whilst tungsten has practically no appreciable effect on the magnetic properties in low carbon steels, it is of great value in high carbon steel, since by its coercive-power with regard to magnetism it greatly increases the power of the steel to retain the magnetism, consequently tungsten is an important metal in connection with special magnet steels, and a high percentage will improve the magnetic properties of the steel very considerably. The composition of the steel used for permanent magnets is somewhat similar to a special tool-steel, but as a magnet steel is not required for cutting purposes, its composition is arranged so as to make most effective its properties of retaining magnetism.

The addition of tungsten will impart a fine-grained structure to a carbon steel, and the fracture of a tool steel containing about 1.3 per cent. carbon and 3 per cent. tungsten may be likened to a mole's back, so fine and velvety is the grain.

Self-hardening steels are alloys of iron, carbon, tungsten, and manganese, and in some instances chromium and other metals are added to bring about certain improvements in the qualities of the steel. These steels are called self-hardening, because if they are heated to a temperature of about 1,200 deg. C. (nearly a welding heat) and allowed to cool in the air, they become very hard.

The hardening and tempering of a piece of steel is an operation which, to the casual observer, may appear a very simple one, but it is undoubtedly one of the most delicate operations in connection with mechanical art.

The quantity and variety of tools and other steel articles that are handled in the Midlands, are so numerous that it is hardly possible to give a detailed description of the rules and methods for forging, hardening and tempering that can be applicable to the whole.

There are certain fundamental laws and principles relating to these matters, and if these are duly and properly observed, and correct methods adopted, they will invariably lead to satisfactory results. In my book, "Machines and Tools Employed in the Working of Sheet Metals," which was published in 1903, I mentioned how necessary it is to exercise special care in heating a tool to the required temperature before plunging it into the cooling bath for quenching, the principal points of importance to remember being gradual and uniform heating, and the quenching to be done in a plentiful supply of fresh clean water and brine, or rain water and brine.

A steel high in carbon will harden at a low heat as compared to the temperature necessary for a steel containing a low percentage of carbon, which fact makes it essential for the workman to have some knowledge as to the carbon content of the steel he is handling; also, he should at least have an approximate idea as to the correct temperature to which the steel had best be heated. What an important item the latter is—will be seen when we come to consider the actual application of the recalescence curve for fixing the correct hardening temperature.

At all stages in its manipulation, steel should be thoroughly and uniformly heated; that is, in the forge and rolling mill, in the smith's shop, as well as in the hardening and tempering shop, for if a piece of steel is hotter in one part than another, the expansion is necessarily variable, consequently contraction in hardening will also vary, there being higher tension in one part than another, resulting in either a warped or cracked tool.

In the forge, irregular heating means irregularity in forging, consequently inequality of tension in the article when in the rough forged state. But a reasonable amount of care on the part of a blacksmith will prevent trouble from this cause.

The difficulties of uniformly heating a piece of steel in an ordinary blacksmith's fire, or in a coal-fired furnace, are far too well known to need much comment from me. In the case of the coal-fired muffle, by exercising a certain amount of care, by occasionally turning round the steel, and by using a pyrometer in the muffle, it is possible to partly overcome the difficulties, but at all times experience and good judgment is necessary. Probably the next best way to ensure a regular heating is to use a gas-fired muffle or furnace, which can be readily arranged to maintain an even and correct temperature by adjusting the gas supply, and in this way considerably reduce the risk of burning the steel; and should a workman be unable to remove a tool immediately it is ready for quenching, the application of a pyrometer will guide him and so prevent disaster. An incidental advantage of the gas-fired furnace is the increased cleanliness, due to the freedom from smoke and dust, which are inseparable where the ordinary blacksmith's fire or coal-fired muffles are employed.

The International Marine Signal Company, Limited, of Ottawa, have closed their shop, and it is rumored in Ottawa that the company has been purchased by Mackenzie, Mann & Company. When a representative of *The Canadian Engineer* called at the company's office in Ottawa last Friday, an official of the company would neither confirm nor deny this rumor, but stated that Mr. Thomas L. Willson, the former president of the company, has resigned from the Board of Directors, and that Mr. Lewis Lukes, of Mackenzie, Mann & Company, Toronto, had been elected president of a new Board of Directors, which would have their headquarters at Toronto. When interviewed this week at Toronto, Mr. Lukes stated that he was not yet in a position to discuss the matter, and that he would be unable to give out a statement for a few days as to just how the affairs of the company would be arranged for the future.

COAST TO COAST.

Port Arthur, Ont.—A new telegraph line has been completed which now affords direct communication between Port Arthur and Toronto. In its construction over 800 miles of copper wire were used.

Winnipeg, Man.—The earnings of the Winnipeg Electric Railway on actual street car operation in the city of Winnipeg for 1913, were $2,384,597.28, an increase of $269,604.48 over the earnings of 1912.

Winnipeg, Man.—The financial statement issued by the provincial department of public works shows Manitoba's Government elevator system to have had a surplus of revenue over expenditures to the extent of $329.84 for the year ending November 30th, 1913. Receipts totalled $58,770.71, and expenditures, $58,440.87.

Weston, Ont.—A recent improvement has been effected at Weston by the Water, Power, and Light Commission in its endeavor to make Weston the best lighted village in York County, Ont. Every pole on each side of the business section of Main Street now bears a heavy-powered light; and on the east side, the lamps are encased in large frosted globes.

Winnipeg, Man.—The report of the public utilities commission shows the condensed earnings of the Manitoba Government telephones for the twelve months ending November 30th to have been as follows: revenue, $1,707,149.74; expenses, $1,269,909.90; and net earnings, $437,239.84. The interest charges for the year were $406,975.20, leaving a surplus of $30,264.64.

Ottawa, Ont.—Some of the improvements at Ottawa effected by the civic council of 1913 are the following: the provision of a good temporary water supply in the form of 11 artesian wells; a reduction in the Municipal Electric Commission's rates; the prevention of increased street railway rates; a civic financial surplus; and a greater mileage in the construction of granolithic walks and pavements than has been accomplished in any previous year.

Toronto, Ont.—The definite announcement has been made by Sir William Mackenzie, president of the Canadian Northern Railway, that September 1st next, will see the completion of the C.N.R. transcontinental from Quebec through to the Pacific Coast; and the early fall, the operation of a passenger service that will require an equipment for the operation of 15 trains each way daily. He states, also, that $50,000,000 were expended last year in construction upon this continental line.

South Vancouver, B.C.—Mr. H. B. A. Vogel, secretary of the North Fraser harbor commission, stated, while addressing municipal ratepayers recently, that progress is being made by the commission. Harbor commissioners in the United States and European countries have been requested for information, and the appointment of a competent engineer is to be made shortly. Until the engineer shall have examined the specifications of the contract, the Dominion government is holding up the jetty and dredging project for the mouth of the North Arm and a distance of five miles inward.

Montreal, Que.—Comprehensive schemes of extension, improvement and double-tracking formed the basis of procedure by the C.P.R. in 1913; but the present year will have to be devoted to the completion of these schemes, rather than to the projection of any extensive new program. Thus, the expenditures estimated for the western appropriations of 1914 are almost entirely confined for the present to the completion of track-laying, etc., on grades already built, on branch lines, extensions and double-tracking, the latter of which will eventually connect Winnipeg to Vancouver; and to the building of the Rogers' Pass tunnel.

Victoria, B.C.—Of the E. & N. Railway company's new line on the east coast from McBride Junction to Courtenay, a stretch of 45 miles, 15 miles have been completed; and when the bridge being erected over the Big Qualicum river is finished, steel work and ballasting will be continued over another 15 miles, upon which grading is complete, and should be concluded by the middle of next April. The road will then have reached the Sable River, in the vicinity of Baynes Sound, where another steel viaduct will be erected, material for which is already on hand. It is estimated that the road will reach Union Bay in May; and on the 10 miles between that point and Courtenay, the Trent river must be spanned. This is not expected to delay the completion of the entire road beyond next July.

Winnipeg, Man.—Since January 1st, 1913, the C.P.R. has completed the largest construction programme ever undertaken by this company on lines west of the lakes in any one year. Eight hundred and fourteen miles of grade have been constructed, 753 miles of steel laid, and 878 miles ballasted, making a grand total of 2,472 miles of additional trackage either completed or partly done. Besides this new construction the new yards in Transcona, with 100 miles of track, have been completed, the new double-track bridge connected over the Red River, and 4,000,000 bushels of capacity have been added to the elevator at Fort William. Besides progress in double tracking the company has made considerable headway with the Weyburn-Lethbridge line, the Swift Current-Bassano line, and the 5-mile tunnel under the Selkirks, which will be completed in three years. Double tracking west of the lakes now totals 860 miles.

Montreal, Que.—A large annex has just been completed to Windmill Point Elevator at Montreal. The main elevator, which was completed and put into operation in the spring of 1906, has a capacity of 1,080,000 bushels. The capacity of the annex is 1,070,000 bushels, which makes a net accommodation of 2,150,000 bushels. There are in the new building 28 concrete tanks, 25 feet in diameter and 100 feet in height, arranged at right angles in four rows, with seven tanks in each row. The tanks are constructed of reinforced concrete, having their adjacent sides rigidly united so that the four-pointed, star-shaped spaces between the circular tanks may be used for storage as well as the circular tanks themselves. The large tanks hold approximately 33,000 bushels apiece, and the star-shaped or interstice bins hold approximately 8,000 bushels each. On the Grand Trunk system, the Windmill Point Elevator is now second only in size to the 5,700,000-bushel elevator situated at Fort William.

St. Catharines, Ont.—The city engineering department has had an exceptionally busy year in 1913, so much so that a second assistant has been required by City Engineer Near for clerical work. Mr. Near, moreover, has undertaken to improve the system of the office department so as to satisfy more fully the requirements of the Legal Department of the Court of Revision in connection with the Local Improvement Act. To this end, he has introduced a card index system giving the history of each local improvement from its recommendation to its completion. Another improvement instituted is printed certificate forms for all payments, giving the required information as to by-laws for the City Treasurer. A third is a file and index to all contracts, by-laws, and agreements. A retention book has also been introduced, giving readily the date when final inspection of such work shall be made to release the guarantee drawbacks. Finally, a system of filing and indexing all plans of sub-divisions, local improvements, etc., is gradually being perfected.

Vancouver, B.C.—The work completed by the B.C.E.R. Company during the past year, shows a total of 9⅝ miles of new track. Other large works outside of the city, constructed during the year include the logging railway from Port Moody to Coquitlam dam; and on Vancouver Island, the

Saanich line extending 22 miles from Victoria to Deep Bay. Work on the construction of Coquitlam dam, which has been in progress since 1908, has been ended and the Jordan River dam on Vancouver Island has also been finished, both works which have cost millions of dollars. The Kitsilano car barns have been erected since the opening of the year; new car barns were added to those already in existence at New Westminster; and the facilities for handling cars have also been greatly improved there by the building of a large interurban freight yard. The No. 2 power house on the North Arm has been fully completed and when fully equipped will have a capacity of 42,000 horsepower. One unit of 14,000 is already practically installed. Work is started, although not finished, on the new power-receiving station in the District Lot 118, Burnaby, and on the building of an extension to the Jordan River power house on Vancouver Island that will double its capacity.

Vancouver, B.C.—It has been announced by Mr. Cameron of the Pacific Dredging Company that of the 4,000,000 cubic feet of material which will have to be removed to make the waterway navigable and provide a turning basin for large ships, 800,000 cubic feet have been already transferred to the site of the Canadian Northern Pacific terminals on the other side of the Main Street bridge. A dipper dredge is being installed to supplement the operations of the hydraulic suction plant; and it is now expected to remove twice the amount of material each day. The hydraulic dredge is working in the narrow arm of the creek adjoining the G.N.R. station. The dipper apparatus will commence operations near the Connaught bridge. The pipe lines from the suction dredge were concentrated for some time on a big hole, 1,000 feet by 1,000 feet, immediately east of the bridge. This had to be filled before any appreciable difference was made on the large area to be reclaimed. The dirt deposited in the creek extends over an area of eighty acres, and already a fair-sized island has been formed east of the bridge. A temporary barrier has been constructed across the creek near the bridge to prevent the material from seeping back into the main portion of the waterway.

Toronto, Ont.—Another discovery of natural gas in Toronto, though not of a pressure to foretell any commercial value, was made while boring operations for a pure water supply were being carried on beneath the new Dominion Bank Building, corner King and Yonge Streets. Indications of a high pressure were at first reported, but they have been discredited by the statements of Dr. A. P. Coleman, Professor of Geology at the University of Toronto, and of Mr. G. G. Grist, General Manager of the Canadian Stewart Company, which is erecting the building. Dr. Coleman stated that, though a gas flow of 700-pounds pressure as had been reported was not impossible, yet the result of numerous boring tests made in Toronto had shown the gas flow found to be very weak. Mr. Grist claims that the vein of gas discovered under the Dominion Bank Building was small and of little consequence. The boring for water had attained a depth of over 1,100 ft., when indications of gas in the shaft caused a cessation of operations, through fear of tapping a voluminous flow at high pressure. The shaft was hurriedly filled with concrete, to a depth of about 300 ft., and thereby a stop was put to the endeavor of the builders to provide the building in this way with a water supply that would obviate the use of the present city supply, and its deleterious effect upon valves, pipes, etc.

Revelstoke, B.C.—Mr. J. P. Forde, district engineer of the public works department, Revelstoke, says in connection with the Columbia river survey, concerning which inaccurate statements have recently been published, that two parties are engaged in the work, and have been in the field for the past two summers. These are in charge of Mr. W. F. Richardson and Mr. H. F. Muerling. While they have not yet completed their work, it is expected that they will do so within a few weeks, and make their report to the Minister of Public Works on the engineering features of the work of making this river a western wheat route to Portland. The report of the minister will not be complete until the economic features of the scheme have been considered. During the season of 1912-13, Mr. Richardson's party was engaged in surveying the river between Golden and Revelstoke, and the report on this work has already been sent to Ottawa; and during the season of 1913-14, that party has been engaged on surveys between Revelstoke and Waneta on the international boundary, and is still engaged on those surveys. The work being carried on under Mr. Muerling has been confined to special surveys in the vicinity of Burton, which is at the lower end of the Columbia river narrows, connecting the Lower and Upper Arrow Lakes. These surveys are being made with the view of improving navigation at the narrows, where improvements will be required in the immediate future, even if the larger scheme of making the river navigable to the Pacific coast should not be put in process. The reports of the field engineers are expected to be complete some time in March; and the report covering both the engineering and economic aspects of the scheme will then be prepared by the Government engineer's department for the consideration of the minister of public works.

Montreal, Que.—Mr. A. S. Baxendale, managing director of the Universal Radio Syndicate, which is carrying out a contract to establish a wireless telegraphic service between Canada and the United Kingdom, while in Montreal, made the following interesting statements: "There will be in connection with the Newcastle installation 6 wooden towers, 300 feet high, and one of steel with a height of 500 feet, while the number of kilowatts will be 300. The San Francisco station, which connects with Honolulu, has but 100; and when it is considered that the range is about the same distance, about 2,000 miles, the power of the Canadian station and its possibilities for a superior service will be understood. The station on the other side of the Atlantic is at Bally Bunion, in County Perry, Ireland, and from there the company will have a line to London, which will be leased from the English post office department. It is expected that arrangements will be successfully completed with the C.P.R. to handle the land business of the Universal Radio Syndicate. Mr. Baxendale stated further that the contract with the Canadian Government calls for 80 words a minute, while the Newcastle and Bally Bunion system will be equal to at least 150 words a minute. He stated also that the United States government in a piece of test work had been most successful at a range of 3,000 miles from the Arlington station, near Washington, and that with only 30 kilowatts and mostly at night. Consequently, one can easily measure the possibilities of the Canadian system. In arranging for 300 kilowatts, the company are looking for the very highest rate of speed yet obtainable. Experimental tests will be commenced at Newcastle in February; but it will probably be early spring before the line is opened for regular transoceanic business.

PERSONAL.

J. LANNING, B.A.Sc., has been appointed superintendent of the sintering plant of the Mond Nickel Company, in their smelter works at Coniston, Ont.

C. KRUMBIEGEL, resident engineer of the Deutsche Maschinenfabrik A.G., has returned from Germany and joined the staff of the company's Canadian agents, Messrs. Gerald Lomer, Limited, Montreal.

JAMES COWIN, formerly Winnipeg manager of C. A. P. Turner's office, and E. F. FEE, of Winnipeg, have formed

a partnership and will make a specialty of reinforcing steel. Their office is at 701 Canada Building, Winnipeg.

J. STOKES, of the firm of Ashmore, Benson, Pease & Company, Limited, Stockton-on-Tees, England, called at *The Canadian Engineer* office last week on his way to England after having spent several weeks in Canada.

HAROLD C. STEVENS, principal assistant engineer to JOHNSON & FULLER, consulting engineers and sanitary experts, New York City, has been admitted to membership in the firm, the other members being George A. Johnson and William B. Fuller.

H. B. TAYLOR, M. Am. Soc. M.E., read a paper, illustrated by slides, on "The Present Practice in Design and Construction of Hydraulic Turbines" before the Montreal mechanical section of the Canadian Society of Civil Engineers on January 15th.

B. E. T. ELLIS, whose article on the West End sewage disposal works at Hamilton, appears elsewhere in this issue, and STANLEY M. OBORN, Toronto, have formed a partnership as consulting and civil engineers, specializing in main drainage works of all kinds, with two offices, one in Toronto, in charge of Mr. Oborn, and one at 158 Cumberland Street, Hamilton, under Mr. Ellis' supervision.

B. E. T. Ellis, C.E.

Mr. Ellis has had 14 years' experience in municipal engineering, in Canada and England, chiefly main drainage work, but including roads, bridges, street railways, sewers, etc. Besides designing the East and West End disposal works, on the 2-story sedimentation tank principle, in Hamilton, he has prepared plans and estimates for the East End main drainage scheme (combined system) for that city, as well as for the new storm-overflow sewer to relieve the existing sanitary sewers in the central part of the city.

Previous to specializing in main drainage work Mr Ellis has acquired a thorough training in the city engineering departments of West Bromwich, Birmingham, and York, England; and of Toronto and Hamilton, Canada. For three years he was an assistant to Mr. Albert D. Greaterox, M. Inst. C.E., a past-president of the Institution of Municipal and County Engineers.

F. C. GAMBLE, one of the vice-presidents of the Canadian Society of Civil Engineers, and chairman of the Victoria branch of the Society, gave an illustrated lecture to that branch recently on engineering work in British Columbia during the past half century.

W. A. McLEAN, Provincial Highway Engineer for Ontario, was in Nova Scotia last week, where he gave two addresses at the Provincial Agricultural College, Truro. One was based upon the principles of road organization, and the second dealt with road construction in Ontario.

WILLIAM H. CONNELL, Assoc. M. Am. Soc. C.E., chief of the Bureau of Highways and Street Cleaning, Philadelphia, Pa., on January 15th delivered an illustrated lecture on "Organization and Methods of Street Cleaning Departments" before the Graduate Students in Highway Engineering at Columbia University.

S. WOLFF, formerly manager of the Cleveland office of the Allis-Chalmers Manufacturing Company, has been appointed Chicago manager for the DeLaval Steam Turbine Company, manufacturers of steam turbines, centrifugal pumps, centrifugal air compressors, speed-reducing gears, etc., with offices in the Peoples' Gas Building.

C. H. RUST, C.E., of Victoria, B.C., is spending a few weeks in Eastern Canada and New York. Last week he attended the annual meeting of the American Society of Civil Engineers, of which he is vice-president, and next week he will attend the annual meeting of the Canadian Society of Civil Engineers, of which he is a past president.

G. R. B. ELLIOTT, of Vancouver, has been awarded the prize for the best paper read before the Pacific North West Society of Engineers during the year 1913. His subject was "The Fraser River Delta." The membership of the organization extends from San Francisco north, the headquarters being in Seattle. Mr. Elliott who is the first Canadian to secure the annual award, is believed to have won it largely because of the volume of original information on the subject contained in his article.

EDMONTON'S NEW COMMISSIONERS.

The City Council of Edmonton has dismissed the entire city commission board, composed of A. G. Harrison, A. J. McLean, and John Chalmers, and has appointed commissioners, each with specific duties. M. S. Booth was chosen commissioner of health and safety, and Bryce J. Saunders, commissioner of public works. John Chalmers was re-appointed and given charge of operation.

COMING MEETINGS.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Annual meeting will be held in Montreal, Que., January 27-29, 1914. Secretary, Prof. C. H. McLeod, 176 Mansfield Street, Montreal, Que.

CANADIAN CLAY PRODUCTS MANUFACTURERS' ASSOCIATION.—Annual Convention to be held at King Edward Hotel, Toronto, Jan. 27th, 28th, 29th, 30th. Secretary, J. R. Walsh, 40 Blake Street, Toronto.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

NATIONAL CONFERENCE ON CONCRETE ROAD BUILDING.—Meeting will be held in Chicago, Ill., February 12th to 14th, 1914. Secretary, J. P. Beck, 72 W. Adams Street, Chicago, Ill.

AMERICAN SOCIETY OF HEATING AND VENTILATING ENGINEERS.—Annual Meeting to be held in New York, January 21st to 23rd, 1914. Secretary, E. A. Scott, 29 W. 39th Street, New York City.

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

THE McKELLAR RIVER BRIDGE AT FORT WILLIAM

PARTICULARS OF THE NEW SCHERZER ROLLING LIFT BRIDGE RECENTLY COMPLETED FOR THE CANADIAN PACIFIC RAILWAY COMPANY —PROVIDES ACCESS TO NEW TERMINAL YARDS ON ISLAND NO. 1

IN our issue of October 2nd a description was given of the new electrically operated Strauss trunnion bascule bridge, the largest double-deck, double-track bridge of the bascule type in the world, which was built for the Canadian Pacific Railway Company in connection with the new terminal system at Fort William, Ontario. The yards and loading docks which the company are developing on Island No. 1, can only be conveniently reached by bridges over the Kaministiquia and McKellar Rivers. These, being both navigable rivers, require the bridges to be of the bascule type. The article referred to above relates to that over the Kaministiquia, while the following is a description of that over the McKellar. This is a single-leaf, four-track, Scherzer rolling lift bridge. This span is 120 ft. to the centre of supports, giving a clear channel of 114 ft., while the track for the segmental girder is 32 ft. long. Two of the tracks are for the railway, while the other two are for electric cars. There are three trusses 31 ft. 6 in. c. to c. and 31 ft. 6 in. deep. The segmental girders have a radius of 25 ft., and when the bridge is rolling or opening, they travel approximately 30 ft.

There are two operating motors, not fixed on the stationary part of the bridge, but moving with the bridge as it opens. The motors are connected by gearing to pinions which mesh with racks on the rack girder, which is stationary.

When the bridge opens, it merely rolls backward. In order to ensure this the segmental girders are meshed into the track girders by means of a form of gearing consisting of square projections about one inch high on the track girders, with corresponding recesses in the segmental girders.

The angle through which the bridge leaf moves between the closed and open positions is approximately 74 deg. No equalizing gear is interposed between the operating pinions and the motors to balance up the stress of each of the pinions, but two couplings have been provided on the main shaft which have to be drilled in the field after all the gears have been adjusted.

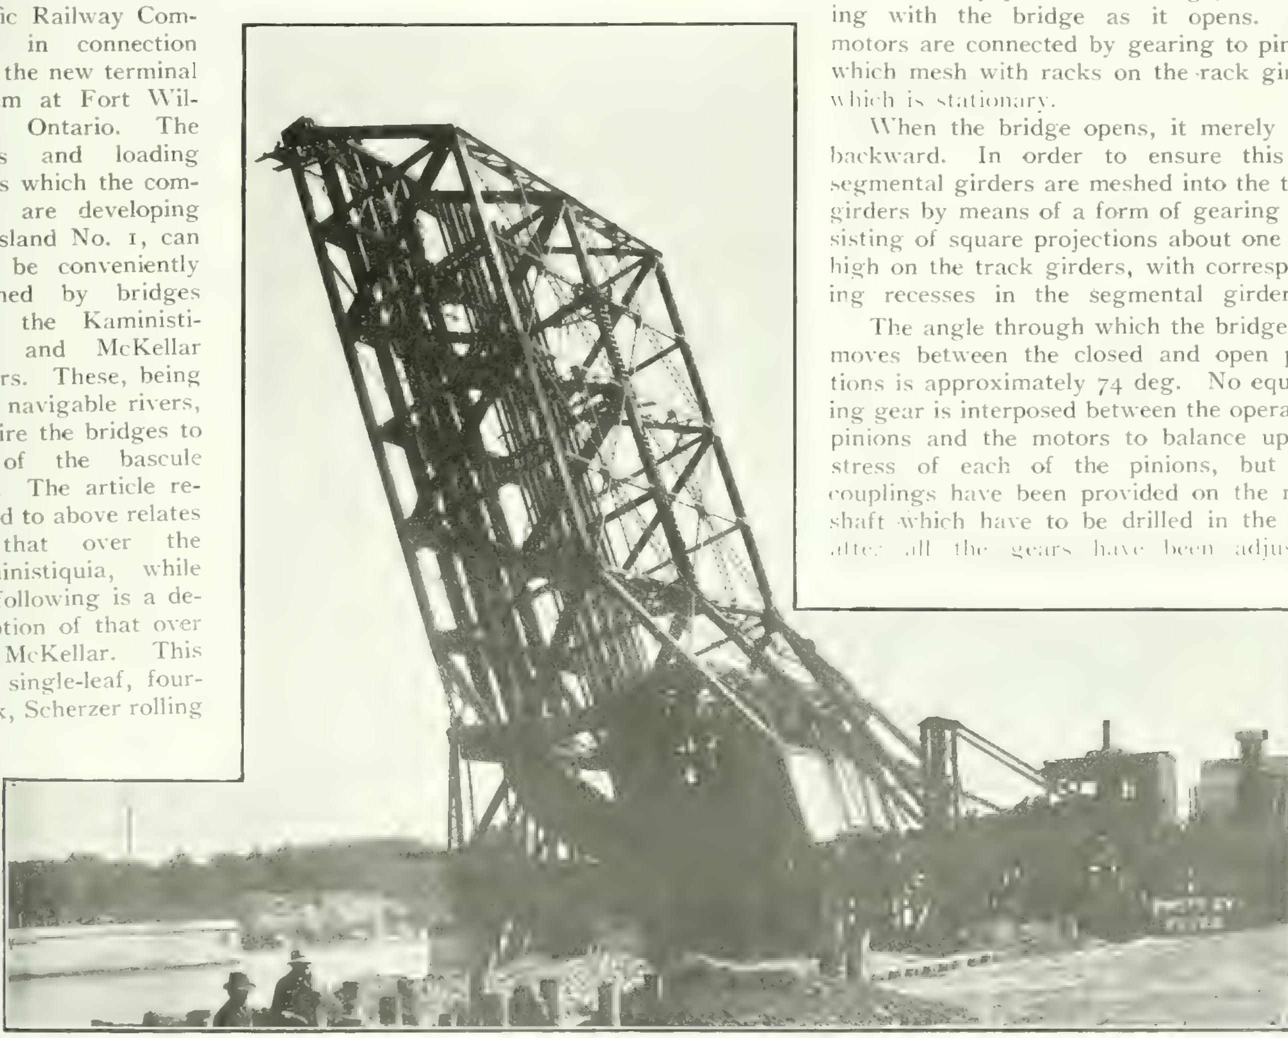

Fig. 1.—Bridge for the C.P.R. Over the McKellar River, Near Fort William, Ont.

Method of Operation.—There are two operating motors, 37-h.p., 680-r.p.m., 550-volt, 60-cycle, fitted with solenoid brakes. As the motors turn through approximately 74 deg. around an axis, parallel to the motor shafts, the bearings have been specially designed. For

the same reason it is not possible to fit the solenoid brakes in the usual manner on the end shield, but the solenoid brake has been turned through 45 deg. This arrangement prevents the solenoids beng in a horizontal position when the bridge is open. The solenoid brakes are provided with release attachment and automatic trip.

For the operating motors two controllers geared together have been used.

The two end locks are motor-operated by a 2-h.p., 1,200-r.p.m., 550-volt, 60-cycle motor. This motor is fitted with solenoid brake, and operates the end locks through worm gearing. The motor only operates in the horizontal position, but as it moves with the bridge, it has been necessary to provide it with special bearings. Provision was also made for operating the end locks by hand, by means of a lever in the operator's cabin. When the end locks have been withdrawn, they are held back by means of catches, and remain in that position during the whole time the bridge is raised. Provision is made for the catches to be knocked out by a stop as the bridge again reaches the nearly closed position. The position of the end locks is indicated in the operator's cabin by means of an indicating lamp, operated through a lock signal switch.

Emergency Brake.—The emergency brake is operated by means of a 3-h.p., 550-volt, 60-cycle motor, which is geared to a crank disc. A pin on this disc is connected to a lever, which releases the brake mechanism. The brake is normally set by a spring. There is a small solenoid brake on the motor which sets when current is applied, and releases when current is off, thus operating in the reverse manner to the usual solenoid brake. A drum type limit switch, mounted on top of the motor and driven by a sprocket chain from the back shaft of the motor, is used to make proper connections. The operation is as follows

Assuming the main brake is set to release the brake, the triple pole line switch on the emergency brake current is closed. The motor immediately starts and makes a few revolutions, bringing the crank disc pin to the upper position. When it reaches this point, the limit switch opens the motor circuit and at the same time energizes the solenoid, thus setting the brake on the motor. This holds the motor and prevents it from rotating backwards. So long as the solenoid brake is energized, the main brake is kept in release. To set the brake, the triple pole switch is opened. This de-energizes the solenoid, and releases the brake on the motor. The force of the spring on the main brake then immediately pulls around the crank disc and resets the brake.

Operation of the Motor and Interlocking System.—When the bridge is closed and ready for traffic, the arm of the lock signal switch and the arm of the bridge signal switch are in the position marked "closed" and the contactors in the circuits of the main operating motors and the lock are open. To open the bridge the first step required is to set the railroad signals at "danger." Until this is done, the lock motor contactors remain open and the end lock cannot be withdrawn. Until the end locks are withdrawn, the contactors of the operating motors remain open and these motors cannot therefore be started.

The action of moving the lever to set the railroad signals at "danger" closes the switch in the railway signal cabin. When this switch is closed, the contactor coils of the lock motors are energized and close the contactors. The circuit breaker is then closed, the controller handle of the lock moved around and the lock withdrawn. As the lock bar moves out it operates the lock signal switch, and this in turn changes the signal lights in the railway signal cabin from white to red, thus indicating that the bridge is

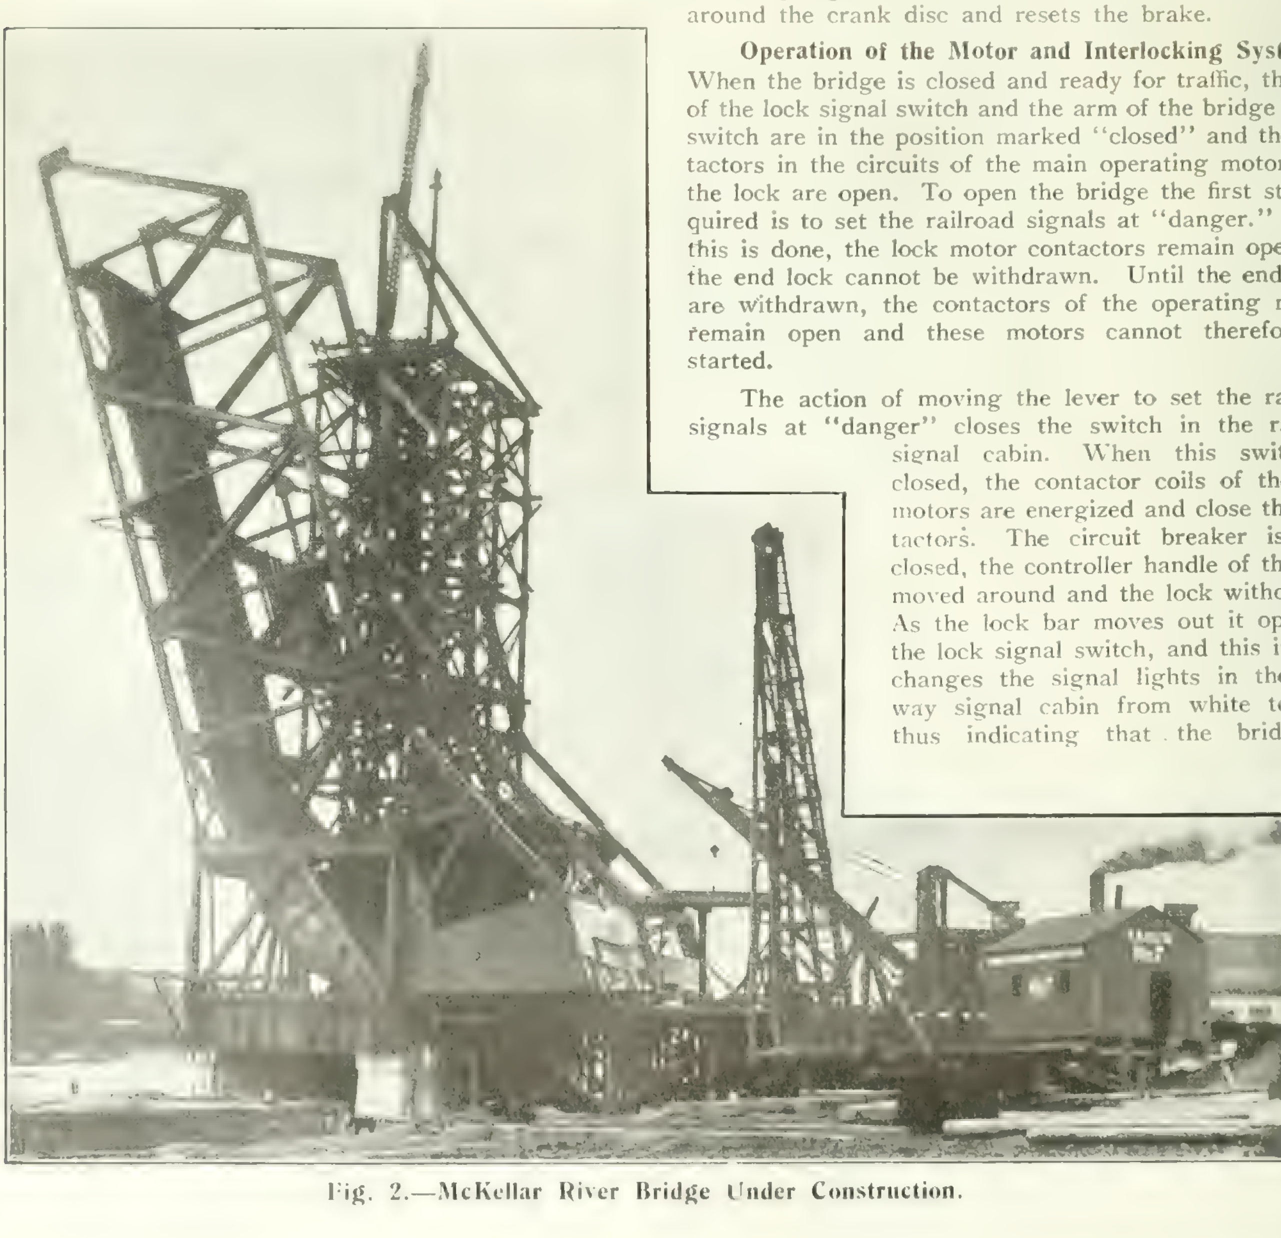

Fig. 2.—McKellar River Bridge Under Construction.

closed to traffic. A similar change in lights takes place on the bridge operator's signal lamp panel, the lights changing from "lock closed" to "lock open." At the same time the lock signal switch closes the circuit of the operating coils of the contactors in the circuit of the main operating motors.

As soon as the "lock open" signal light has shown up, the handle of the controller should be moved to the "off" position and the circuit breaker opened. If the controller handle is not thrown to the "off" position in time, the low voltage release coil of the circuit breaker will be short circuited through a set of contacts on the lock signal switch in series with a set of auxiliary contacts on the controller. It will be noticed that the circuit breaker of the lock motor must either be opened by hand or tripped automatically as above, before the oil switch for the main operating motors can be closed, for the auxiliary switch on the circuit breaker opens the circuit of the low voltage release coil on the oil switch when the circuit breaker is closed.

After closing the oil switch, the emergency brake is released by closing another switch. The main operating motors can then be started and the bridge raised by moving around the handle of the controllers. The first notch on these controllers releases the solenoid brakes only on the motors and this notch can be used at any time when it is desired to allow the bridge to coast. As soon as the bridge starts to open, the arm of the bridge signal switch moves from the position marked "closed" and thereby opens the contactors in the lock motor circuit. This prevents the end lock being operated while the bridge is open. As long as the bridge is closed the "fully closed" light (white) on the signal lamp panel shows up, but as soon as the end of the bridge lifts off of the pier, this light is extinguished. An auxiliary indicator switch mounted on the end of the moving leaf of the bridge was used for this light as it was found impossible to obtain a definite indication of the "closed" position of the bridge by means of the bridge signal switch operated by the movement of the bridge. The remaining lights, however, on the signal lamp panel, which show up in turn as the bridge opens, are operated from contacts on the bridge signal switch. The channel lights which change from red to green when the bridge opens are also operated from this switch. If the operator fails to throw the controller handle to the "off" position after the "nearly open" signal light has shown up, the low voltage release coil of the oil switch is short circuited by means of a set of contacts in the bridge signal switch in series with contacts in the controller. This arrangement trips the oil switch, cutting off current from the motors and setting the solenoid brakes. If through any cause switch mechanism should fail to operate and open the switch, an alarm bell, which is connected in place of the usual series resistance of the low voltage release coil, rings continuously until the operator throws the handle of the controller to the "off" position.

In closing the bridge the handle of the main controller is, of course, moved around in the reverse order. No automatic cut-off is used when closing the bridge as a set of air buffers are provided to prevent shock to the structure when the end of the bridge strikes the pier. If the bridge is traveling too fast, these air buffers will cause the motors to be overloaded and so trip the oil switch. The bridge can, if necessary, be held down on the pier by keeping the controller on the second or third notch until the emergency brake is set—thus holding the bridge in position. The controller handle is then moved to the "off" position and the oil switch is opened. The circuit breaker of the lock motor is then closed and the lock moved into place. In closing the lock, the circuit breaker will also be tripped out unless the controller handle is moved to the "off" position as soon as the "lock closed" signal light shows up. When the lock is closed all signal lights show up white, indicating that the bridge is safe for traffic. During those times when the bridge is closed and the locks in place, the lock motor circuit breaker is closed so that the auxiliary switch disconnects the alarm bell and low voltage release coil of the oil switch from the 110-volt busses. A set of emergency knife switches are provided on the switchboard panel, which, when closed, cut out the main motor and lock motor contactors respectively. These switches are normally sealed in the open position and would only be made use of in case of damage to any of the contactors or some other emergency condition requiring operation of the bridge independently of the interlocking system.

The bridge signals described above are interlocked with the railway company's interlocking system in such a way that a train would be derailed if it attempted to cross while the bridge was in the open position.

Erection and Details.—The bridge was erected in the open position by means of a stiff-leg derrick mounted on top of a wooden erection tower 125 ft. high. The pouring of the concrete for the counterweight was carried on simultaneously with the erection of the steel so as to balance the structure at all times during erection.

The current for operating this bridge is obtained from the Kaministiquia Power Company and is 2,200-volt, 3-phase, 60-cycle, A.C. current, stepped down to 550 volts for use on the bridge.

The electrical control apparatus is housed in an operator's house on one side of the bridge.

The bridge is also equipped with a hand operating mechanism for use in case of an emergency.

The total weight of the steel work and machinery is approximately 660 tons.

The bridge was designed by the Scherzer Rolling Lift Bridge Company, of Chicago, under the direction of Mr. P. B. Motley, engineer of bridges for the Canadian Pacific Railway Company.

The bridge was fabricated by the bridge department of the Canada Foundry Company in their Toronto works and all calculations in regard to counterweight, etc., were worked out in their engineering department after the shop drawings were made.

The entire electrical equipment was furnished and installed by the Canadian General Electric Company.

PROSPECTIVE C.P.R. DEVELOPMENT IN THE WEST IN 1914.

The Canadian Pacific Railway appropriations for Western Canada in 1914, are almost entirely confined to the laying of steel on over 600 miles of track now graded and waiting for it; to branch line extensions, and to the building of Rogers' Pass Tunnel. There will be a continuation of the double-track work, which was pushed so vigorously in 1913, and the close of the year will find great strides having been made toward connecting Winnipeg with Vancouver by a double track line.

The appropriations also provide for the completion of the terminals at Winnipeg, Calgary and Vancouver.

SOME FALLACIES IN CEMENT TESTING.

A DANGER that invades the testing of cement, in that it frequently leads to numerous unfounded complaints and disputes as to its quality, is the judgment expressed from results obtained by an inexperienced operator in carrying out such tests. These operations are no longer exclusively confined to the laboratory of the expert as they once were, and almost every user of cement in any considerable quantity either carries his own tests on the material, or delegates the work to one of his staff. W. L. Gadd, F.I.C., M.C.I., read a very interesting paper at a meeting of the Concrete Institute of Great Britain on December 11th, 1913. Although the address did not enlarge materially upon the recognition of cement testing as a highly specialized work requiring a skilful and extended knowledge of the properties and characteristics of the material, it was clearly pointed out that several fallacies appeared to underlie some of the recognized or suggested processes of testing. The author observed, at the same time, that the accuracy of the testing was necessarily so pronounced that the mere following of instructions given in a booklet or a specification would not suffice.

In the main, the paper dealt with the fallacies mentioned above, and the points in the British standard specifications which appeared open to criticism. The portion of his paper dealing with this phase of the subject is reproduced as follows:—

The standard specification stipulates that before any sample of cement is submitted to certain tests it "shall be spread out for a depth of 3 in. for twenty-four hours in a temperature of from 58 deg. to 64 deg. Fahr."

The object of this procedure appears to be twofold—i.e., (*a*) to cool the cement to the normal temperature of the atmosphere, and (*b*) to obtain conditions similar to those governing cement which has lain in sacks or casks for two or three weeks—i.e., during the possible period between shipment and use.

As regards (*a*), this can be very simply done without exposing the sample to air; as regards (*b*), the author has made experiments which show that there is no relation between the effects of aërating cement for twenty-four hours and storing in sacks for two weeks or a month; further, that the setting time is differently affected when the same cement is aërated or stored in bulk in different localities or at different periods. In some cases the effect of twenty-four hours' aëration is the opposite to that produced by storage, and storage or aëration at one period has an opposite effect to storage or aëration at another period. For instance, one sample aërated for twenty-four hours at the beginning of the month of July resulted in a quickening of both initial and final sets, whereas the same sample aërated for twenty-four hours in the same room a fortnight later resulted in the exactly opposite effect on setting time.

This appears to effectively dispose of the somewhat prevalent idea that changes in setting time are due to some inherent property of different cements. The erratic behavior found is common to all the samples tested, the composition of which varied within considerable limits, the lime contents, for instance, ranging from 64 to 59 per cent.

The retardation or acceleration of setting time on storage or aëration cannot, therefore, be due to peculiarities in the cements themselves, but must be due to chemical changes brought about by the absorption of some constituent present in the atmosphere.

Cement has a strong affinity for moisture in the first place, and for carbonic anhydride in the second place, and these constituents are present in the atmosphere in variable proportions at different times and in different localities.

From former experiments and reasoning I have held the opinion that absorption of moisture results in a retardation of setting time, while absorption of carbonic anhydride produces an accelerating effect. Cement exposed to both influences will therefore have its settling characteristics affected one way or the other according to the relative amounts of moisture and carbonic anhydride absorbed, the net effect being the resultant of the two opposing forces.

In order to test this theory I have made the following laboratory experiments, where the conditions can be under control and standardized, which is rarely possible in so-called "practical" tests.

A quantity of slow-setting cement (600 grammes) was placed in a large glass tube, which it half filled, and a current of purified air, freed from ammonia, carbonic anhydride and moisture, passed over it continuously for twenty-four hours. The total volume of air passed through the apparatus was about 173 litres.

The air was purified by being bubbled through dilute sulphuric acid (which served to measure the rate of flow as well as to remove any ammonia vapors), then drawn through a soda-lime tower to remove carbonic anhydride, and finally through a large calcium chloride U-tube to remove every trace of moisture. U-tubes of calcium chloride and of soda-lime were also attached to the exit end of the cement tube and between this tube and the pump.

The loss constituents and the setting time were determined both before and after the treatment. Further quantities from the same sack of cement were then treated in a similar manner to a current of moist air, freed from carbonic anhydride and of carbonic anhydride itself respectively, and examined in the same way. The results indicate that pure, dry air has no effect upon the setting time of cement, the loss constituents remaining practically constant.

On the other hand, the effect of moist air freed from carbonic anhydride is distinctly marked, although the percentage of moisture absorbed is comparatively small.

This is probably due to the fact that the cement taken for the experiment was already high in loss constituents, the total loss on ignition being 2.39 per cent.

The acceleration of setting time by absorption of carbonic anhydride is clearly proved.

Fineness.—The British standard specification stipulates that the fineness of grinding shall be such that not more than a certain percentage of residue shall remain upon a sieve of a stipulated mesh, under the conditions of the test. It is obvious that the most important point in this connection is to ensure that the sieves used shall be of standard and definite dimensions, and this is provided for by the following clause:

"The sieves shall be prepared from standard wire, and the diameter of the wire for the 5776 mesh shall be .0044 in. and for the 32400 mesh .002 in. The wire cloth shall be woven (not twilled), the cloth being carefully mounted on the frames without distortion."

The standard specification, therefore, stipulates that for the first-named sieve there shall be 76 warp and 76 weft wires of a definite diameter; and for the second sieve 180 warp and 180 weft wires of a definite diameter per square inch.

When sifting cement through a sieve to obtain the proportion of particles too large to pass through the interstices between the wires, the size or area of the individual holes appears to be the only condition of importance; and it is to be assumed that the intention of the framers of the specification was to ensure this condition being standard.

If a definite number of wires of a definite thickness be *equally* spaced throughout the unit of measurement, the spaces between the wires will be of definite and equal area; but the weaving of wire cloth has not yet attained such a standard of excellence as to ensure that the wires (especially in the finer counts) are spaced equally throughout the piece, or even throughout any individual inch; and I have examined many rolls of cloth which contained the stipulated number of threads, of practically the correct diameter, and yet were hopelessly inaccurate for the purpose of testing cement for fineness.

I submit that the size or area of the holes in a sieve is the real standard, and should be stipulated, the actual diameter of the threads, or their precise number per inch, being of secondary importance.

In the course of my duties it falls to me to examine and to accept or reject numerous pieces of sieving cloth for use in a number of cement works and testing laboratories, and I have formulated a specification for my own use which aims at a standard sieve, while at the same time recognizing and allowing for the great difficulty of weaving cloth of this nature with extreme accuracy.

This specification, for 180^2 sieves, I state as follows:

(1) The standard area of the holes in inches is $.00355^2$.

(2) The equivalent mesh, calculated from the actual average area of the holes, as measured, shall fall between 176^2 and 185^2.

(3) The mean variation from the standard width of holes shall not exceed 10 per cent.

(4) Not more than 10 per cent. of the holes measured shall exceed a variation of 15 per cent. from standard.

It is my practice to measure with a micrometer microscope about 300 to 400 spaces in several different parts of a roll of cloth; and I find it is possible to obtain cloth to conform to the foregoing specification, and that such cloth gives in use very fairly consistent results; whereas sieves which conform to the British specification —as worded—often give, in testing, most erratic results; in one case the difference between two sieves, both of which contained the correct *number* of wires per inch, amounting to 20 per cent. of the total residue.

Another point which appears to be overlooked is the size of the sieve itself. The British specification stipulates that 100 grammes of cement shall be sifted for a period of fifteen minutes, but does not specify the total area of the sieve to be used. I have seen in use sieves varying in size from 4 in. diameter to 9 in. or 10 in. square; and it is obvious that the same weight of cement, sifted for the same period of time, will be more effectively sifted over a larger area than over a smaller one.

The following actual experiments bear this out: A sample of cement was thoroughly mixed, and 100 grammes sifted for fifteen minutes through each of two sieves prepared from the same wire cloth, but differing in sifting area. The larger sieve had a total area of 64 in.^{2}, while the smaller one had a total area of 12 in.^{2}.

The residue on the larger sieve was 16.4 per cent., while on the smaller sieve it was 19.8 per cent., a difference of 17 per cent. of the total.

Another and very finely ground sample, tested in the same was, gave 3.5 per cent. of residue on the larger sieve, and 5.6 per cent. on the smaller one—a difference of 37 per cent. of the total. I admit this is an extreme case, and that nobody in his senses would nowadays use a sieve so small as 4 in. by 3 in. Nevertheless, this sieve was actually in use not so very long ago.

Specific Gravity.—The specific gravity test is now used in place of the old method of taking the weight per striked bushel, which has for some time been discredited, and rightly so.

The weight per bushel had no real bearing upon or relationship to the degree of calcination, but was chiefly influenced by the fineness of grinding. The fallacious character of this test was well known to cement experts long before its abolition from so-called up-to-date specifications, in some of which it appears, even to-day, as the "weight per litre test.'

The specific gravity test is still retained in the British standard specification, and is considered by most people to fulfil the functions formerly attributed to the bushel weight test—viz., to detect the degree of burning to which the clinker has been subjected—or, in other words, it is a test for under-burned cement. This, however, is a fallacy. The specific gravity of cement affords no indication of the degree of calcination, and it has long been known that the figure was affected much more by atmospheric influence than by any difference in burning. This is recognized by the standard specification so far that the specific gravity is stipulated to be 3.15 when freshly burned and ground, and 3.10 when the cement has been ground for one month. This difference of .05 is a greater difference than lies between the gravities of good clinker and the lightest under-burned "yellow" respectively, as will be presently pointed out.

The specific gravity of carbonic anhydride and of water being .88 and 1.00 respectively, it will be readily seen that comparatively small proportions of these substances, absorbed from the atmosphere, are sufficient to reduce the gravity of cement to a material extent.

Butler has shown that if the absorbed water and carbonic anhydride be expelled by igniting the cement, the specific gravities of cements of various makes become so nearly identical as to afford no indication of quality.

The conclusions reached by Butler were: (1) That the specific gravity of cement is no indication whatever of proper calcination. (2) That the specific gravity depends upon the age of the cement, and the opportunities it has had of absorbing water and carbonic anhydride from the air.

These conclusions are quite in accord with the experience and the opinion held by myself for some time past.

In 1904 or 1905 F. M. Meyer found, as the result of some hundreds of tests on freshly burned clinker, that the highest specific gravity was obtained when the clinker was burned at a temperature of 1,290 deg. to 1,370 deg. Cent. This clinker gave cement which was expansive and unsound.

As the burning temperature was raised, the specific gravity was decreased, but the clinker became sound.

My own experience is that when taken freshly from the kiln, the specific gravity is practically the same, whether the clinker be well burned or under-burned, provided the carbonic anhydride has been all, or nearly all, expelled from the chalk.

The specific gravity of cement being merely a measure of the degree of aëration which the sample has re-

ceived, and the finer particles being naturally more absorbent of water and carbonic anhydride than the coarser pieces, it follows that a finely ground cement containing much flour will more rapidly have its original specific gravity reduced by aëration than will a coarsely ground sample, and would thus, falsely, appear to be the more lightly burned of the two.

Standard Sand.—There is a somewhat general idea that tensile or crushing tests of cement with standard sand represent the best results of which the cement is capable. This is erroneous. Sand tests do not give the highest results which can be got out of the cement, but give results which are standardized, and therefore comparable with those obtained by different operators. The crushing strength, especially, of concrete or mortar, depends largely upon the size and character of the aggregate, the absence or presence of dust, clay matter and other things, and the density of the mass. The use of standard sand merely gives results which are comparable, and only represent the strength of a cement when tested under certain conditions and with an aggregate of a definite size and character.

The standard sands employed and specified in different countries vary in size to some extent. These differences in size of grain doubtless have their effect upon the results obtained.

From results obtained by me it appears that the crushing resistence of concrete made from the same cement varies not only with the size, but also with the character of the aggregate.

Autoclave Test.*—This test, recently proposed by Mr. H. T. Force, in charge of testing materials on the Delaware, Lackawanna and Western Railroad, of Scranton, Pa., is merely a revival of Dr. Erdmeyer's high-pressure steam test introduced in Germany about 1881, and rejected by German cement experts as being unreliable and misleading. In the words of Prof. Gary, of the Royal Bureau of Material Testing, it is even less adapted to distinguish useless cements from useful cements than the usual methods of determining constancy of volume. According to Dr. Cushman, of Washington, the details of the test have been several times revised during the last twelve months, but the procedure is now as follows:—

For each test three neat briquettes are made, and after twenty-four hours in a moist closet these are weighed and then placed in the autoclave, sufficient water being added to cover them. Pressure is then raised by heating the apparatus by gas burners or other suitable means, the time taken to raise the pressure to 295 lb. per square inch being not more than one hour.

The pressure is maintained at 20 atmospheres for a further period of one hour, at the end of which time the autoclave is slowly blown off, the briquettes removed (when their condition permits) and placed in the moist closet for one hour. They are then re-weighed and broken in the cement-testing machine in the usual manner. The tensile strength so obtained is compared with that of twenty-four-hour neat briquettes kept in moist air, and must show an increase of at least 25 per cent. over the latter. The autoclave briquettes must also develop a strength of at least 500 lb. per square inch, and the gain in weight must not be greater than 1 per cent. Expansion bars, 1 sq. in. in section and 6 in. long, are also made up and tested for expansion after twenty-four hours in the moist closet and two hours in the autoclave. The expansion of these bars must not exceed one half of 1 per cent.

Under this test some cements develop greatly increased strength while others were reduced to powder. Comparison of results, extending over twelve months, showed that the failure could not be due to the presence of free lime; but it was thought to be due to the presence of coarse granules of cement which are not hydrated when the cement is gauged, but which might threaten the stability of the structure by subsequent hydration after a lapse of time.

The disruption of the briquettes by the hydration of the coarser particles of cement clinker, under high pressure and heat, is probably correct. I myself drew attention to this in an article published more than six years since, but numerous experiments have convinced me that such coarser particles hydrate eventually in the cold without expansion. If it were otherwise the whole of the concrete work, in this and other countries, carried out with coarsely ground cements during the last twenty years, should now be in a very precarious condition.

I have made a number of tests with the autoclave with somewhat erratic results, but with finely ground modern rotatory cements the Le Châtelier expansion of which did not exceed 2 mm., the whole of the samples, with one exception, conformed to the test as laid down. The one exception, curiously enough, was the most finely ground member of the series, the residue on the 180^2 sieve being only 1.6 per cent.

On the other hand, a number of samples ground to the fineness stipulated in the standard specification—viz., from 12 to 18 per cent. on the 180^2 sieve—failed to withstand the conditions of the autoclave test, although they were perfectly sound when tested by the ordinary boiling or Le Châtelier methods.

I hold that growth of strength by age is of less importance and is not such a criterion of quality as is generally considered. Modern cements prepared from purer clinker, and much more finely ground than formerly, attain a strength approximating to the maximum much more quickly, and it is evident that a cement which attains, say, .8 of its maximum strength at short dates has less margin for growth than one which only develops .5 of the maximum in the same time.

The stipulated pressure to be maintained in the autoclave (20 atmospheres) is needlessly high, and serves no useful purpose. The same effect is produced at a pressure of 5 atmospheres as at 20 atmospheres.

There is, therefore, nothing to be gained by carrying out the test at the high pressure advocated in America.

With regard to the utility of such a test, it must first be shown that cements which pass the simpler soundness tests generally employed in this country will yet be dangerous in ordinary work, and secondly, that the autoclave test will detect such cements with certainty. So far neither of these points has been demonstrated.

Free Lime.—No theory connected with Portland cement has obtained a stronger hold, or has attained such hoary antiquity, as the idea that unsoundness of cement is due to free lime locked up within the particles of the ground material. In fact, this theory has been for so long accepted that to question it may possibly be met with derision.

Nevertheless, I confess I have never been a believer in this bugbear, the existence of which has never been demonstrated, although many abortive attempts to do

*See *The Canadian Engineer* for Sept. 11, 1913, (p. 444).

so have been made. Certainly free lime, in the sense in which it has generally been understood, cannot produce the blowing or disruption which occurs with unsound cement, because an addition of free lime, in the form of ignited calcium oxide, has the effect of reducing expansion by inducing the hydration of particles of hard clinker grit, in the same way that ammonia or ammonium carbonate does so.

The improvement in soundness, brought about by the exposure of cement to a damp atmosphere, lends some apparent support to the contention that free lime is thereby slaked and rendered harmless; but it is rather difficult to understand how the small amount of moisture absorbed from the air penetrates the particles and slakes the free lime when the enormously greater quantity of water used in gauging the cement fails to touch it. Furthermore, unsound cement stored for some time in airtight receptacles, in which, presumably, no slaking of free lime can occur, becomes perfectly sound.

Exposure of cement to air for a few days sometimes results in an increase in the amount of expansion, as tested by the Le Châtelier method, and this increase is nearly always proportionate to the amount of aëration undergone—i.e., the thinner the layer in which the cement is laid out, the greater the increase of expansion.

This phenomenon was pointed out by me in an article published in 1907, and was the subject of a paper presented to this institute by Mr. Butler in 1910. The facts are therefore well authenticated, and they are directly opposed to the theory that expansion of cement is caused by free lime.

We know very little yet of the properties of lime in a state of solid solution. It is stated to be crystalline and to hydrate slowly; but if the solid solution theory be correct, crystalline free lime is present in considerable quantity in all Portland cements, whether sound or unsound, and it has not been satisfactorily explained why the lime hydrates without expansion in one cement, but does so with destructive force in another.

It is also well known that a low-limed cement is often more unsound than a high-limed cement, which, again, is antagonistic to the free lime theory.

My own view is that unsoundness in cement is probably due to the presence of an abnormal silicate, perhaps dicalcium silicate, which is an unstable compound and slowly disintegrates with an increase in volume. The phenomenon of "creeping clinker," known to cement makers, is an illustration of the disintegration, with increased volume, of dicalcium silicate, which is formed when clinker contains an insufficiency of lime; and this or a similar compound is most likely to be found in unskilfully made cement in which the proportions of lime, silica, and alumina are not present in correct combining weights, or when the temperature of burning is insufficiently high to induce the formation of those silicates and aluminates which constitute true Portland cement.

A new departure on the part of the government of Great Britain recently, and one which caused great comment, was the request made to four private firms to tender for the construction of submarines of a new type, and concerning which the greatest secrecy has been maintained. The new type is said to be as far in advance of previous submarines as the Dreadnought is over the pre-Dreadnoughts. It is said to have a speed of over twenty knots, with a wide radius of action. It will be equipped with wireless; its guns will be superior to the armament of the present destroyers; and it is expected to revolutionize naval warfare.

ECONOMIC CONDUIT LOCATION.

THE paper entitled "Economic Canal Location in Uniform Countries," by Lyman E. Bishop, Assoc. M.Am.Soc.C.E., which appeared in Vol. 74, Transactions Am. Soc. C.E., contains a series of interesting and useful diagrams, by the use of which the locating engineer can quickly determine the economic centre line cut for any particular canal section for any slope of ground. The subject is followed up, particularly in several of its phases, by C. E. Hickok, Assoc.M.Am. Soc.C.E., in a paper appearing in the December Proceedings of the Society, who claims that every conduit, unless it is in a country of uniform topography, must change at certain points from one type of construction to another, in order to be built economically and safely. It is rarely that a conduit of any considerable length can consist entirely of canal section, but rather it must change to flumes, siphons, pipes, bridge flumes, or tunnels, as the conditions demand. The points of change are determined,

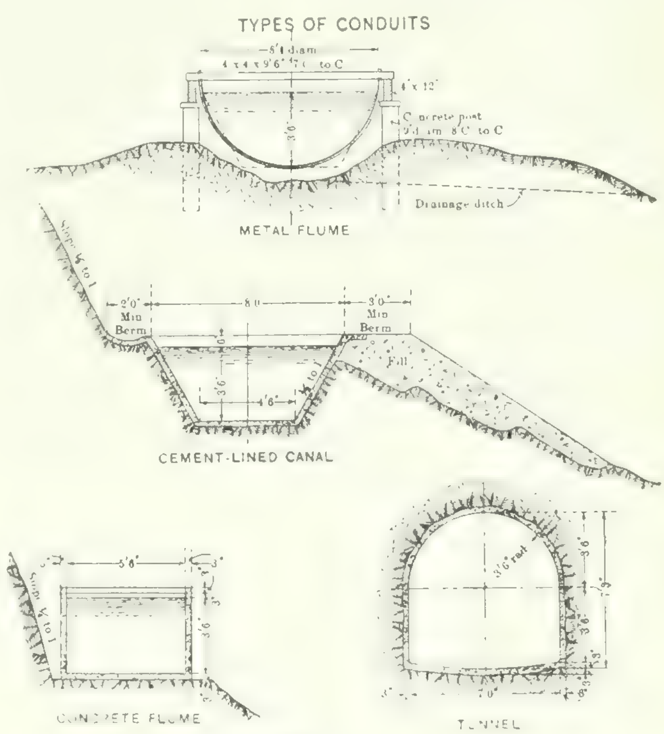

Fig. 1.

not only by the slope of the ground, the nature of the material encountered, and certain local conditions, but by economic considerations as well.

In making conduit locations, from time to time, the writer has evolved a diagram, giving the equivalent lengths, from an economic standpoint, of various types of conduit, which has been of considerable value. For instance, when the locator comes to a point where he must decide whether to tunnel through a ridge or follow the grade around with a canal, he measures the length of the two possible routes, and, by an inspection of the diagram, comes to a ready decision. This not only eliminates considerable loss of time, but, if the diagram has been properly constructed, assures a proper and complete comparison between the two alternatives as to first cost, depreciation, head-loss values, evaporation and seepage loss values, interest, taxes, inspection, and repairs.

For purposes of illustration assume a case where the project under consideration is to be used for irrigation

and hydro-electric purposes, and where the conduit has a capacity of 44.6 cu. ft. per sec. and a slope of one-tenth of 1 per cent. Four types of conduit are shown in Fig. 1.

It is obvious that for each foot saved in length of conduit there is a saving in head loss, as well as in evaporation and seepage losses. The value of this saving is ascertained in the following way, taking 1,000 ft. of conduit, for convenience in calculating:

Head Loss.—1,000 ft. of conduit dissipates 1 ft. head. With a discharge of 44.6 cu. ft. per sec., and 77% efficiency, the horse-power is

$$\frac{1 \times 44.6 \times 62.5 \times 0.77}{550} = 3.9 \text{ h.p.} = 2.8 \text{ kw.},$$

less 10% for transmission and transformer losses
2.61 kw. at $55 .... $ 143.50

Evaporation Loss—Power Value.—Assuming an evaporation of 5 ft. per annum:

$$\frac{8 \times 1,000 \times 5.0}{43,560} = 0.915 \text{ acre-ft. per year}$$

= 0.0025 acre-ft. per 24 hours = 0.00125 cu. ft. per sec. with a head of 1,500 ft.

$$\frac{0.00125 \times 1,500 \times 62.5 \times 0.77}{550} = 0.162 \text{ h.p.}$$

= 0.121 kw.,
less 10% for transmission and transformer losses
= 0.109 kw. at $55 .... $ 6.00

Seepage Loss—Power Value.—From tests made by Elwood Mead, M. Am. Soc. C.E., and B. A. Etcheverry, Assoc. M. Am. Soc. C.E., at the University of California, the writer concludes that the rate of percolation through a 3-in. canal lining under a head of 3.5 ft. is about 0.0043 ft. per hour, or 0.103 ft. per 24 hours.

$$\frac{8 \times 1,000 \times 0.103}{43,560} = 0.0188 \text{ acre-ft. per 24}$$

hours = 0.0094 cu. ft. per sec.

$$\frac{0.0094 \times 1,500 \times 62.5 \times 0.77}{550} = 1.23 \text{ h.p.}$$

= 0.92 kw.
less 10% = 0.828 kw.,
0.828 kw. at $55 .... $ 45.54

Total annual power loss	$ 195.04
Capitalized at 10%	$1,950.40
or per foot	1.95

Evaporation Loss—Irrigation Value.—0.0025 acre-ft. in 24-hours (from the foregoing) = 0.00125 cu. ft. per sec. = 0.0625 miner's inch. Assume 25% loss before delivery to consumer:

0.047 miner's inch at $0.40 per miner's inch per day = per annum .... $ 6.86

Seepage Loss—Irrigation Value.—0.0188 acre-ft. per 24 hours (from the foregoing) = 0.0094 cu. ft. per sec. = 0.47 miner's inch, less 25% loss = 0.353 miner's inch at $0.40 per miner's inch per day = per annum 51.64

Total annual irrigation loss	$ 58.50
Capitalized at 10%	585.00
or per foot	0.585

Résumé:

Power loss per foot	$1.95
Irrigation loss per foot	0.585
Total loss per foot	$2.535

The first cost and the annual charges of each type of conduit are next computed. The annual charges are taken as consisting of the following items: interest, depreciation, taxes, inspection, and repairs. The annual charges of each conduit are capitalized at 10% and added to its first cost, which gives a figure having a real comparative value. For instance, we obtain the comparison between a lined canal and a concrete-lined tunnel as follows:

Concrete-Lined Canal.

First Cost—Per Foot—		
Excavation, 2 cu. yd. at $0.36......	$0.72	
Concrete, 4.25 cu. ft. at $10.20 per cu. yd.	1.57	
		$2.29
Annual Charge—		
Interest at 10%	$0.23	
Depreciation at 2%	0.046	
Taxes	0.019	
Inspection	0.01	
Repairs	0.02	
	$0.325	
At 10%		3.25
		$5.54

Concrete-Lined Tunnel.

Excavation, 2.25 cu. yd. at $5.50 ...	$12.40	
Concrete and forms	4.10	
		$16.50
Annual Charge—		
Interest at 10%	$1.65	
Depreciation at 1%	0.165	
Taxes	0.137	
Inspection	0.01	
Repairs	0.02	
	$1.982	
At 10%		19.82
		$36.32

It is evident, if we shorten the conduit by building the tunnel, that the first cost and the capitalized annual cost of the tunnel can exceed the first cost and the capitalized annual cost of the canal by an amount equal to the length of conduit saved multiplied by the loss value per foot of conduit. This is shown by the equation:

$$Y(C_y + A_y) - X(C_x + A_x) = (X - Y)V$$

where X = linear feet of canal,
Y = linear feet of tunnel,
C_x = estimated cost per foot of canal,
A_x = estimated annual charges per foot of canal capitalized at 10%,
C_y = estimated cost per foot of tunnel,
A_y = estimated annual charges per foot of tunnel capitalized at 10%,
and V = value of losses per foot of conduit.

In the case of a tunnel, the evaporation will be considerably lessened, thereby effecting an additional saving. If entirely eliminated, this saving would amount to 12.8 cents per ft., as shown above. This was reduced to 10 cents and the first cost of tunnel credited with that amount. Inserting the proper values in the equation:

$Y(16.40 + 19.82) = X(2.29 + 3.25) + (x - y) 2.53$

$Y = 0.208 X$, the equation of a straight line.

In the same way, any two types of conduit can be compared and the resulting straight-line equation obtained. The diagram, Fig. 2, which is self-explanatory, shows the results.

In the case where a siphon crossing a gulch is compared with a canal or flume passing around the head of the gulch, the cost of the siphon is credited with the saving in evaporation and seepage throughout its length, which in this case amounts to $1.10 per ft.

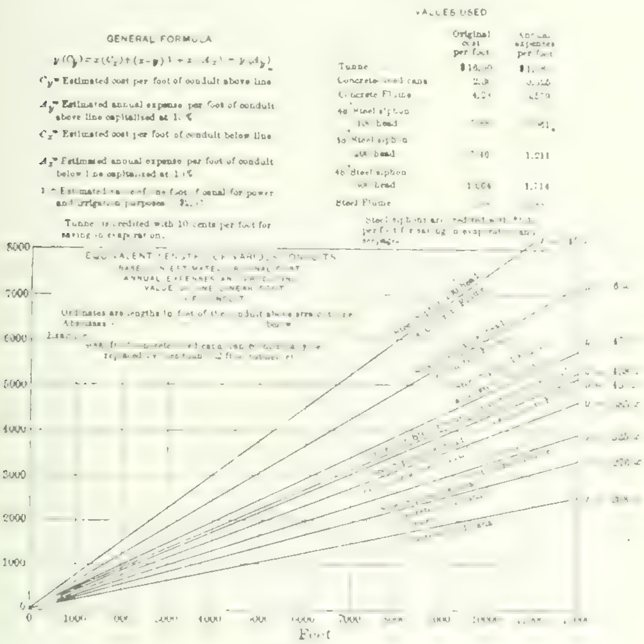

Fig. 2.

The writer realizes that such a diagram cannot be relied on entirely in the location of a conduit, for there are local conditions on every piece of work which must be taken into account.

M. Claude Casimir Perier has published two exhaustive volumes dealing with facts and figures concerning the utilization of the geographical and physical advantages of Brest, and the transforming of the deepest, broadest and best port of western Europe into the great Old World centre for maritime commerce with North, South, and Central America, and, by means of the Panama canal, with the Pacific coast of America and Asia. He shows that Brest is, with the exception of Lisbon, nearer to Colon than any other port in Europe, being only 4,412 miles distant from the Panama canal, 2,954 from New York, and 4,873 miles from Rio de Janeiro. It is not affected by the tidal difficulties encountered off Havre and the ports of the English channel; and it is larger than any other port of Europe. Its depth of water is twelve metres alongside the quays and at the shallowest part of its channel; and this could with comparatively slight cost be deepened to fifteen metres. Brest is only 624 kilometres (389 miles) from Paris, and with improvements on the French railroad lines, would become the terminal of a trunk line to Paris and would also be connected by means of three other trunk lines, not touching Paris, with Calais, Belgium, Germany, Switzerland and Italy. It can also be readily made the feeding point for the French inland canals. The scheme also includes the establishment of a great central railroad station in Paris, possibly near the Palais Royal, which would place the other main line terminals in Paris in communication for passenger and freight. The total cost is estimated at $530,000,000; but M. Perier points out that during the last eighty years France has paid more than five times this sum on the improvements of its ports alone, and to-day has not a single one that can accommodate 50,000-ton liners.

COMPARISON OF WOOD PAVING IN EUROPEAN COUNTRIES AND IN AMERICA.*

By S. R. Church,

Manager Research Dept., Barrett Manufacturing Co.

It has been stated that creosoted wood blocks make the ideal pavement if the following faults could be eliminated: The tendency to expand, resulting in bulging, and sometimes upheaval of the pavement; dislocation of curbs, etc. Slipperiness. Exudation of oil, or "bleeding."

Therefore, in any comparison of our pavements with those of Europe, it is natural first to inquire whether these faults are observed in the European wood pavements, and if not, why not.

Of all the wood pavements that I saw in London, Paris, Berlin and other cities, none of them exhibited any of the foregoing defects, with the exception of two or three slight bulges noticed in London.

Two incidents that have come under my observation within the last few months may be worth relating here. One is the case of a wood pavement recently put down in one of our largest cities on an important business street. A few days after the work was completed I noticed twenty or thirty blocks comprising three parallel rows for a distance of six or seven feet across the pavement, laid with the grain horizontal instead of vertical. After a few weeks, this was apparently brought to the attention of the contractors, and the blocks taken up and relaid. The other incident was the rejection of a low bid on a good-sized wood paving contract, because the sample of oil submitted with the bid yielded, on distillation, one-half of one per cent. more at a certain temperature than the specification allowed. I am perfectly certain that neither one of these things could possibly happen in London. Perhaps nothing that I can say will better illustrate the difference in conditions.

Wood Paving in England.—Creosoted wood is, without question, the most highly esteemed paving material in the English cities. In ten of the twenty-eight boroughs constituting the City of London, and comprising the most thickly populated sections of the city, the total mileage of creosoted wood block in 1912 was 121, and of this total 40 miles was in the City of Westminster. As most of you know, Westminster is that part of London containing the best retail business streets; the government buildings, theatres, museums, art galleries, etc., the social heart of the city. The streets of Westminster are important thoroughfares. The traffic is, however, very largely rubber-tired. In fact, the percentage of iron-tired traffic, if known, would probably be surprisingly low. There are a few exceptions, such as the Strand, where there is considerable mixed traffic, but on the whole, the streets of Westminster and those of purely residential boroughs, such as St. Mary Lebone, Kensington and Wandsworth, which together contribute ninety miles to the total of London wood paving, carry a traffic comprising a tremendous number of vehicles, but of a very non-destructive character to pavement. The City of London proper contains only eight and one-half miles of wood paving. Here the traffic is, of course, intense in all respects.

*Extract from a paper presented at the annual meeting of the American Wood Preservers' Association, New Orleans, Jan. 20th, 1914.

All of the other English cities have adopted wood paving for some of their best streets. Liverpool has approximately 150,000 square yards; Birkenhead, 95,000; Birmingham, Nottingham, Bristol, in fact, all English cities over 50,000 population have wood block streets, and in the majority of cases these are the principal thoroughfares of the town.

I have already stated that European pavements did not bleed; that they are not slippery; and that, at least so far as my own observations are concerned, there is very little expansion sufficient to cause trouble. In England two classes of wood paving exist, soft and hard The hardwoods are ordinarily laid untreated, and will not be considered in this paper, except to state that they are going out of favor very rapidly, and that the existing hardwood pavements are, as a rule, rough and noisy. These pavements comprise the Australian Jarrah and Karri, species of Eucalyptus. Great things were hoped of these woods when first introduced, but their use has unquestionably proved a failure. The creosoted softwood pavements presented, in general, a good appearance, but not equal to the appearance of our best wood block streets. I have said that they were not slippery. This is because the wood is soft enough to permit the pounding into the fibre under traffic of the gravel or coarse sand which is spread over the pavement, and the pieces of grit become permanently embedded in the surface of the wood. It can readily be understood that such a surface will not be slippery. It can also be readily appreciated that it will not present as attractive an appearance, nor would it be quite as noiseless as our creosoted yellow pine.

The wear of the blocks is, in general, very uniform, and but few streets are seen where depressions, pot-holes or inequalities in the surface exist, although in the downtown streets of London proper, where traffic is heaviest, there are several exceptions to this general good condition.

From a casual observance of the wood block surfaces in London, one accustomed to the appearance of our pavements marvels at the apparent absence of replacements. It requires very close scrutiny of the pavement to find the places where service cuts have been made, and where the pavement has been patched. The great care with which this work is done to produce such good results is in marked contrast with the careless manner in which the blocks are sometimes thrown back into place after a service cut in one of our city streets.

I was able to visit the treating plant of one of the most important paving block companies. They are using almost exclusively wood of the class known as "pinus sylvestris," and which is sold under various names, such as "Swedish pine," "Baltic pine," "yellow deal," "red deal," etc. I found this to be a most uniform appearing wood, block after block could be examined without any noticeable difference in weight, size of rings, freedom from knots, shakes, etc., nor is there as marked a difference apparent between heart and softwood as in our yellow pine. The manager of this company told me that he has made a study of wood for many years, and has been all over the world, and that in his opinion this Baltic pine is the ideal paving block wood, and to it he ascribes the success of their pavements. The methods in the plant appear to be thorough and well regulated, but not nearly as up-to-date mechanically as our American works. The saws are small; the treating cylinders are small, and there is a great deal of hand labor. Straight pressure treatment is used. The average treatment is about ten pounds per cubic foot. The City of London now requires twelve pounds, and the city of Westminster ten pounds. The oil is coal tar creosote oil, said to be about 1.06 specific gravity. Specifications are very simple, and so far as I can learn there is practically no inspection at the plant.

Considering the apparently light treatment, the penetration of the oil is exceedingly good (sample). This company lays most of its own blocks, and a large proportion of its contracts are in London. These blocks are delivered to the street in wagons. The storage capacity for untreated or treated material at the plant is small, so that the wood is not seasoned very long before treatment, nor do the blocks remain in storage after treatment for any length of time. In most of the London paving, the blocks are delivered just about as fast as they are required. They are seldom piled along the sides of the streets.

Laying Wood Paving in London.—In company with Mr. G. W. Tillson, Commissioner of Public Works, Brooklyn, New York, I had an opportunity of carefully observing the construction of a wood pavement in Gracechurch Street, London. We were both greatly impressed with the good workmanship displayed. The street is in the heart of the old city, and is 34 feet wide. It was being paved for a distance of about six blocks. The contractors were allowed to shut the street off from traffic for a definite period of time, within which the work must be completed. The old asphalt pavement had been entirely removed, and a new cement-concrete foundation 9 inches deep, was put down. This concrete was put down in sections about 25 feet long, and the full width of the street. It was laid in one course, with a very wet mix, the metal being Thames gravel and sand. The concrete surface was finished to an absolutely true grade by means of a wood templet, and without the use of any mortar course. Sometimes a mortar course is used to make the surface smooth. In all cases the concrete is allowed to set six or seven days until perfectly hard, and the blocks are then laid directly on the hard, smooth concrete, without any cushion. This is universal practice, not only in London, but in Paris and Berlin, and all the engineers with whom I talked said that they were opposed to the use of a sand cushion or a soft cushion of any kind. The blocks were 5 inches deep by 3 inches wide by 7 inches long. They were very uniform in length and exceedingly true in depth. They were laid fairly close, but not rammed. An expansion joint 1½ inches wide was provided along either curb, and two rows of blocks laid parallel to the curb, with a pitch-filled joint between these rows. The expansion joint along the curb was filled with clay to within ½ inch of the top. Before paving up to projections, such as manholes, pipe valves, etc., the blocks are fitted with great care around all these projections. Over the finished surface after the blocks are laid, a flush coat of hot coal tar pitch, of about 140-145° F. melting point, was poured from hand buckets, and this was immediately squeegeed over the surface with rubber rollers, forcing it into all the joints. This was followed with a thin wash coat of cement grout, and finally a substantial layer of fine, brown, siliceous gravel, free from dust or loam, which was allowed to remain on the surface until pounded into the blocks by traffic.

The foregoing is typical of modern English practice. I have seen statements to the effect that spacing lath are commonly used in the joints, but this practice has been abandoned, except in the case of some hardwood pave-

ments. The spacing strips are never used in London or Paris with softwood blocks. They are, however, used in Berlin. The flush coat of pitch over the surface is the universal practice in England, although not used to any extent elsewhere. Longitudinal expansion joints are always provided, even on heavy traffic streets, but lateral expansion joints are not used. In London, 5-inch blocks are used on all important thoroughfares, and no blocks less than 4 inches deep are ever used.

Creosoted Wood Paving in Paris.—Creosoted wood block paving in Paris is more noticeable for quantity than it is for quality. Up to the end of 1911, they had 200,000 square meters, equal to about 280,000 square yards of wood paving. As in England, they have used both hard and soft woods. Hard Australian woods were used to quite a large extent, but have not given satisfactory results. The report of the Chief Engineer of Bridges and Streets of Paris, at the London Road Congress, stated that the average life of the hardwood paving was six years. The appearance of the creosoted pine pavements in Paris varies from good to exceedingly bad. There are many streets where the blocks are decayed. There are also many very rough streets, and on the whole, they are distinctly inferior to the wood block streets in any of our American cities.

Manufacture of Paving Blocks in Paris.—I was fortunate in being able to inspect the municipal wood block plant, through the courtesy of M. de Puligny. This is a very large and well ordered plant, and the first thing that attracts attention is the very high lumber piles, which approximate 40 feet. The sticks are run up into these piles direct from the cars by means of an electric tiering machine. A large proportion of the lumber is kept under glass roofs. There is also a very large storage yard for treated blocks. A new electrically driven machine, which saws 16 blocks at once, is a feature of the plant. The sticks are fed automatically to the saws, and the blocks are discharged automatically with the grain up, to the inspection table, from whence they are loaded by hand into very small iron treating cars. Five or six of these cars full of blocks are run under the creosote oil tank, where each car is filled up by gravity with oil at a temperature of 80 degrees C. After remaining in this bath of oil for twenty minutes, the oil is drawn off from the bottom of the car, and the blocks taken to the storage yard. The average absorption by this treatment is three pounds per cubic foot. Naturally, the penetration is very slight. It is not surprising that the blocks decay before they are worn out, but at first sight it is very surprising that they do not bulge and buckle continually.

An interesting feature of the Paris plant is the machines for shaving old blocks for relaying. Blocks taken up from the street, if not too badly worn or decayed, are brought to the plant and the edges trimmed on these machines. It is sometimes done with portable machines on the streets. Many of the blocks being repaired in this manner for relaying showed hardly any evidence of treatment, and some were partially decayed. The Paris engineers freely admit that their blocks have been very insufficiently treated, and that the results have been unsatisfactory, and, in fact, they are now erecting a new plant for pressure treatment by means of a process developed by M. Labordere. As he has discussed this process in a recent paper before the Sixth International Congress of Testing Materials, I will not at present describe it. M. Labordere told me that it is their intention to use, in connection with this process, a mixture of coal tar pitch and creosote oil of not less than 1.08 specific gravity. They have been using for the dipping treatment an oil of about 1.04 specific gravity.

The woods used in Paris for creosoting treatment are Baltic pine, and pinus maritimas, a native pine largely used at present. This is a much wider grained wood than the Baltic pine, and less uniform in character. They make an interesting distinction between the resinous or gummy wood from the lower part of the trunk, and the wood from the upper part of the trunk, using the former for heavy traffic streets and the latter for ordinary work. I do not know to what extent they are able to carry this out in practice.

I saw two or three wood block streets in course of construction. Five-inch blocks were being put down, and in general, the method is much the same as in London. The concrete foundation is very similar in appearance, and the absence of any soft cushion especially noteworthy. Expansion joints 1½ inches wide along the curbs are filled with sand. Two rows of blocks are laid parallel to the curb with 1-inch between the rows, a peculiar type of sectional expansion joint being used, consisting of a bituminous paper box about 6 inches long, containing hollow paper cylinders. This keeps dirt, etc., out of the joint, and crushes readily under pressure. Transverse joints about 100 feet apart are also filled with these bituminous boxes. On another street a collapsible metal expansion joint is used (Sketch). Instead of pitch grouting, it is common practice in Paris to flush the surface with cement grout, which fills the joints that are open. The work did not seem to be as well organized or as rapidly carried on, nor did the surface of the finished pavement present as uniform an appearance as the London work already described.

In another street I saw 5-inch Swedish pine blocks being laid. The grade was at least 2½ per cent. In this case the surface was flushed with coal tar pitch poured by hand, and forced into the joints by the use of hot smoothing irons. This was followed by a heavy covering of coarse sand. I was told that this method of filling joints was not as common in Paris as the cement grouting method.

Wood Block in Berlin.—There is not much wood block paving in Berlin, but a condition which seems rather remarkable exists, in that on streets paved with asphalt, where the grade becomes too steep and the asphalt will prove unduly slippery, wood block is used. Most of the approaches to bridges are paved with creosoted wood block.

Berlin has probably the finest sheet asphalt paving in the world. Their wood paving is rough and comparatively noisy. About the only thing of especial interest noted in Berlin was that a new wood block plant has been erected where the Rueping process will be used for treating Swedish pine similar to that used in England. I was shown blocks treated by this process, which appeared to have very good penetration with a minimum use of oil (sample).

In the beginning of this paper I stated that European wood pavements did not bleed, expand or buckle, and were not slippery. Let us inquire briefly into the reasons, and see what we have to learn from their methods.

Conditions are so entirely different that I do not see how any direct comparison can be made. In the first place, as to slipperiness, I have already explained that the non-slipperiness of their pavements is due to the use of softer wood. As to bleeding, they seldom have any

weather in London hot enough to cause bleeding. In Paris there is not enough oil in the blocks to cause bleeding. The climate also undoubtedly plays a very important part in the question of expansion and contraction. It is agreed that the sudden expansion that sometimes takes place in our wood pavements is due to a rapid absorption of moisture, usually after the pavements have been unduly dry. This can hardly occur in England, where they have a little rain all the time, very seldom any torrential downpours or any long continued dry spells. The average humidity is high. It is a question whether the pavements ever get dried out to anything like the extent that ours do. I should say that generally the blocks are in a maximum condition of expansion. The same must be true in Paris, or the inadequately treated blocks in that city would certainly bulge. On the other hand, it is well worth considering if the kind of wood that they use has something to do with the lack of expansion troubles. It is manifestly a very different wood from our longleaf yellow pine. As I have already stated, it does not present as attractive an appearance, and it is probably not so durable. It may be, however, that with shortleaf pine or tamarack or Douglas fir, we could obtain results more nearly approaching the European results by following their practice more closely with regard to treatment and methods of laying.

I believe we can afford to give careful consideration to the question of lighter treatment, but I do not believe that because ten or twelve pounds is ample in London with the wood they are using and the climate that exists, it would be ample for our woods in our climate.

The points that I would especially emphasize for your consideration are:—

1. The great care used in the preparation of the concrete foundation and, in fact, in the whole workmanship of the pavement.

2. The general use of deeper blocks.

3. The universal practice (in England) of sealing the joints of the pavement with coal tar pitch, so as to prevent the entrance of moisture.

I would also emphasize what I hope has been suggested to you by a reading of this paper, that the pavements in Europe (this does not apply only to wood), are laid and maintained by workmen who have more conscience, or at least, take greater pride in their work than we find on the average job in our country. There is less inspection on the part of the city of the operations of making the blocks and laying them, but I got a very strong impression that the manufacturers are taking no chances of having their material condemned on account of carelessness or bad workmanship.

In conclusion, I want to repeat that in my judgment, none of the European wood paving surpasses our best wood streets in appearance.

In a recent paper, read by Marcus Machol before the Society of Automobile Engineers, he notes among the claims of magnalium, an alloy of aluminum with 5 to 20 per cent of magnesium, that it has been used for the cylinders and pistons of gasoline engines and for other purposes, and has attracted special attention for aeroplanes and other uses requiring lightness; that its specific gravity is 2 5/10, that of aluminum being 2 6/10, and that of cast-iron, 7 5/10; and that, while tough instead of brittle, it shows a tensile strength of 23,000 pounds per square inch, cast-iron showing 18,000 to 20,000 pounds. As a bearing metal it shows less friction than babbitt or phosphor bronze. It melts at 125 degrees F., which is often exceeded in the engine cylinder, but the pistons do not get as hot as those of iron, because the magnalium heat-conductivity is 14 times as great as that of iron.

BILLINGS BRIDGE OVER RIDEAU RIVER, OTTAWA, ONT.

This bridge is required to replace the wooden structure erected in 1880 by the Township of Gloucester, Carleton County. The present wooden bridge, composed of a series of king post trusses, carried on timber cribs, is in a state of decay and collapse, so much so, in fact, that timber bents have had to be placed under the main channel spans as the bridge can no longer rely on the trusses as a whole, carrying their loads to the piers, the top chords of several of them having by this time assumed a spiral formation. The bridge marks the boundary between the City of Ottawa and the Township of Gloucester and, though at a point not yet thickly populated, is on one of the main arteries into the city. A considerable portion of the farm produce consumed in the city comes in over this route, as many as 800 vehicles and 1,200 foot passengers having been observed to cross in one day.

Disputes on the part of the township authorities as to their proportion of the cost of the new structure have been responsible for the delay in building the new bridge, which in view of the above facts is obviously needed.

The new steel bridge is a commodious structure, carrying as it does two electric car tracks, two 15-ft. roadways and two 6-ft. cantilever sidewalks, thus giving ample provision for future requirements.

It was thought by the designers that economy could best be effected by following the well-known method of making the cost of the substructure equal as near as possible that of the superstructure, and with that objective the crossing was divided into 5 equal spans of about 78 ft. each.

On account of the very high flood which occurs at this point every spring, it was impossible to use a deck construction while consideration also had to be given to the fact that land damages were inevitable at the north or Ottawa end of the bridge, because of the necessity of raising the finished road elevation above that of Bank St. (of which the bridge is a continuation). The engineers were confronted with the problem, therefore, of either incurring excessive land damages or of reducing the clearance between flood level and bridge seats to a minimum. The latter course was decided upon, a minimum clearance of 1 ft. allowed, the finished elevation of the bridge roadway being fixed some 7 ft. above that of Bank St. and the approach being commenced at a point some 190 ft. from face of abutment, which produces a grade of about 3½%.

To effect this a heavy through plate girder construction was adopted, which in combination with its floor-system reduces vibration to a minimum, and approaches the monolithic as closely as can be done in steel construction.

The main girders were designed for the worst possible condition of loading, the maximum moment for each girder being considered a criterion, with 2 cars covering the span and with sidewalks and roadway loaded to 100 lbs. per sq. ft. While this condition is an extreme, it is a condition that is not impossible. Live load stresses were increased for impact according to Ketchum's formula.

$$I = \frac{S \times 150}{L + 300}$$

where L = loaded length of bridge in feet producing the maximum stress in member;

S = computed live load stress;

I = impact to be added to live load stresses.

No remarkable features were met either in the design of the main girders or floor beams, but in the design of the floor-beam connections a common error was avoided, i.e., that of attaching the floor beam to the stiffeners of the main girders, so producing serious secondary stresses, which are avoided by riveting directly to main girder web.

Although the wind stresses in the lateral system are comparatively small it was deemed advisable on account of the great width of roadway to design these members as struts, 4 latticed angles placed 12 in. back to back being used. A double system of bracing was used in each panel as the width of roadway, 48 ft., to length of panel, 15 ft., would render a single system ineffective, besides necessitating details of an objectionable character.

The 4 piers and south abutments will be carried down to rock, test borings having shown this to be from 10 ft. at abutment to 15 ft. at north pier below normal water level.

The north abutment will be piled, concrete being taken down about 10 ft. below water level; borings show rock at this point to be about 25 ft. below water level.

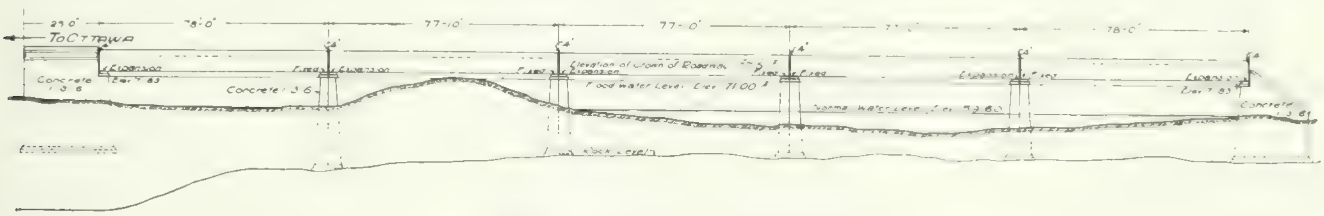

Fig. 1.—Upstream Elevation.

The City of Ottawa having only a 60-ft. right-of-way at the north approach, it was necessary to build a U abutment, keeping it as closely as possible on city property. The south abutment, however, is built with wing walls. It is quite necessary on this side as a cross road passes along the river bank, making it imperative that a good sweep be obtained for vehicles turning off on to the bridge. A U abutment would obviously be dangerous to traffic under these conditions.

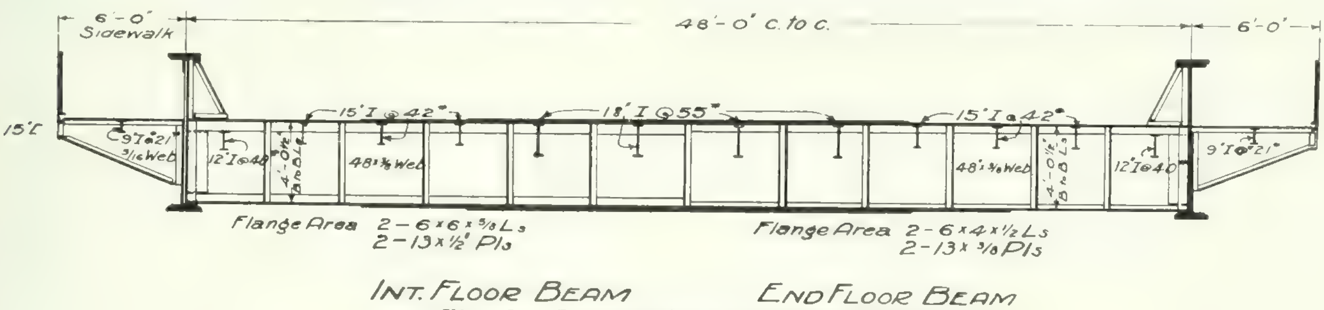

Fig. 2.—Cross-section of Billings Bridge.

Expansion is provided for in the usual manner by roller bearings.

The roadway is carried on a 4½-in. reinforced concrete slab, supporting a 4-in. creosoted wood block wearing surface placed on a 1-in. sand cushion, drainage being effected by a camber of 6 in. at the crown of the roadway, and weep holes being placed at the centre of each panel about 2 ft. from each main girder.

Traffic will be maintained during the erection of the new bridge, by a temporary structure placed about 100 ft. east of the present bridge.

The superstructure was proportioned to carry the loads specified for electric railways on Diagram "B" of the Dominion Government specifications for bridges and for a 16-ton road roller at any point on the bridge.

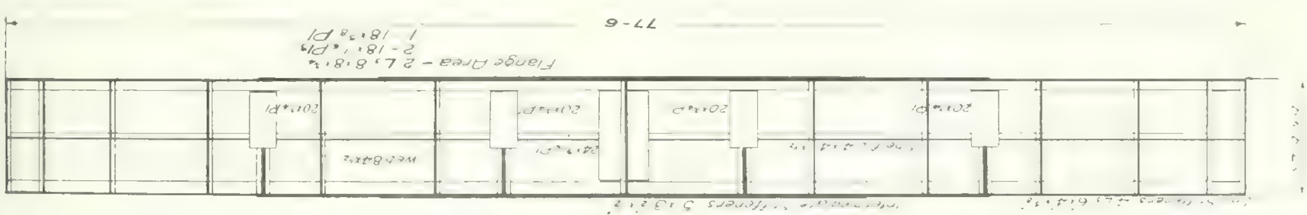

Fig. 3.—Inside View of Main Girder.

Sidewalks are formed with a 3-in. reinforced concrete slab with 1-in. cement finish, with a slight slope outwards sufficient to drain.

Designs for sub- and superstructure were carried out under the direction of Mr. Archibald Currie, city engineer, Ottawa, Ont., Canada.

The largest turbines yet constructed are those constructed for the new Cunard liner, the "Aquitania." They weigh about 1,400 pounds, and have cost thousands of pounds in both experiment and construction. The company has benefited by the experience gained from the building and running of their other turbine ships, so that, in the case of this new vessel, an exceptionally high degree of economy is maintained by passing steam successfully through high-pressure, intermediate, and low-pressure turbines to the condenser, instead of, as formerly, direct from high to low pressure. This ensures more work from both coal and water. A special feature is the arrangement made for going astern. Each of the four propeller shafts has an independent turbine for this purpose. There will be over a million turbine blades in the engines, which, if placed end to end would reach more than 140 miles.

PUBLIC WORKS MELFORT, SASK.

By Roy G. Sneath, B.A.Sc.

THE town of Melfort is situated in Northern Saskatchewan. It is approximately 60 miles east of the city of Prince Albert, and 500 north-west of Winnipeg on the Swan River-Prince Albert branch of the Canadian Northern Railway. A branch line south from Melfort to Humboldt, Sask., on the Winnipeg-Edmonton main line of the C.N.R., is nearing completion.

Fig. 1—Interior of Power House, showing Switchboard and Compression Tanks.

The town has a population of about 1,600, composed almost entirely of English-speaking people. The surrounding country is probably the richest and best suited for mixed farming in the province, and the town has every prospect of rapid and substantial growth.

In the fall of 1911 the town council called on Messrs. McArthur & Murphy (now Murphy & Underwood), consulting engineers, of Saskatoon, for estimates covering the cost of waterworks, sewers and electric lighting system for the town. Accordingly plans and specifications were rendered by the engineers and were approved of by the town. Contracts were let approximating $150,000 and construction started during the middle of the 1912 summer season.

Power House Structure and Equipment.—The power house, situated ½ mile south-west of the main part of the town, is a brick and hollow tile structure, 40 ft. in width and 70 ft. long. The walls are about 20 ft. high, rising to a peak roof, and are made up of 4½-in. brick backed by 4½-in. of hollow tile. Figs. 1 and 2 are interior views.

The power is supplied by a 150-h.p. Diesel oil engine, direct connected to a 90-k.w., 22,000-volt, 3-phase, 60-cycle generator, which is in turn direct connected to an exciter, a shown in Fig. 2. The switchboard is composed of 3 panels of blue Vermont marble. The first controls the generator and exciter; the second controls approximately ninety 100-watt, 6.6-ampere series tungsten street lamps. The third, or motor panel, takes care of the various motors in the power house and another at the deep well. The generator, exciter and switchboard were supplied and erected by the Canadian General Electric Company. The Canadian Boving Company supplied and installed the engine.

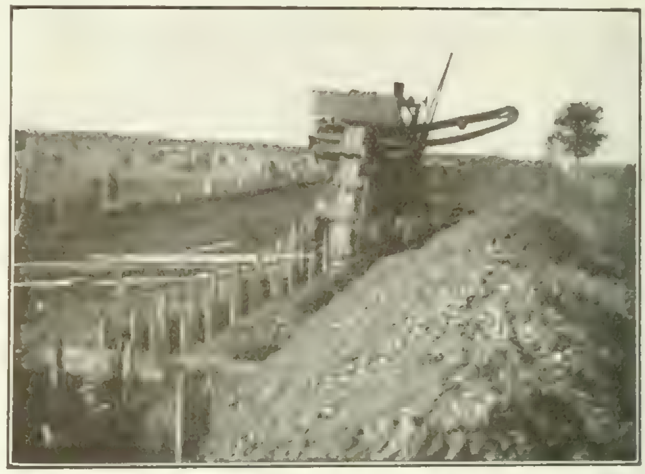

Fig. 4—Excavating 20-ft. Trench from Town to Disposal Works.

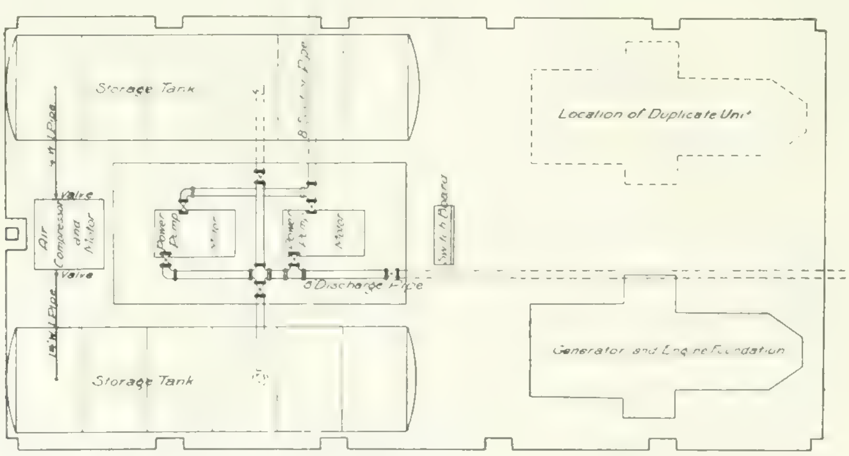

Fig. 3.—Plan Showing Arrangement of Machinery in Power House.

A 5-ton travelling crane was installed in the power house, and proved itself almost indispensable during the installation of the machinery.

Water System.—The source of water supply is in a gravel bed two miles westward from the town. After tests were made to assure sufficient flow of water a circular well was sunk to about 18 ft. in depth, with an inside diameter of 20 ft. It is a concrete structure, with walls 12 in. thick to the ground line and 9 in. above the surface. A reinforced concrete floor at the ground line carries a 20-h.p., 3-phase, 220-volt vertical motor, which

is direct-connected to a submerged centrifugal pump, capable of delivering 300 gal. per minute against a 60-ft. head. This pump discharges through approximately 10,500 ft. of 8-in. steel pipe into a rectangular concrete reservoir, 24 x 64 x 15 ft. deep, which is located near the power house.

each with a capacity of 300 Imp. gal. per min. against a pressure of 80 pds. per sq. in., are located in the power house, and pump water directly into the town mains, or into the pressure tanks. The pressure tanks are connected by a 1¾-in. wrought iron pipe to a horizonal double-acting air compressor, which is back-geared to a

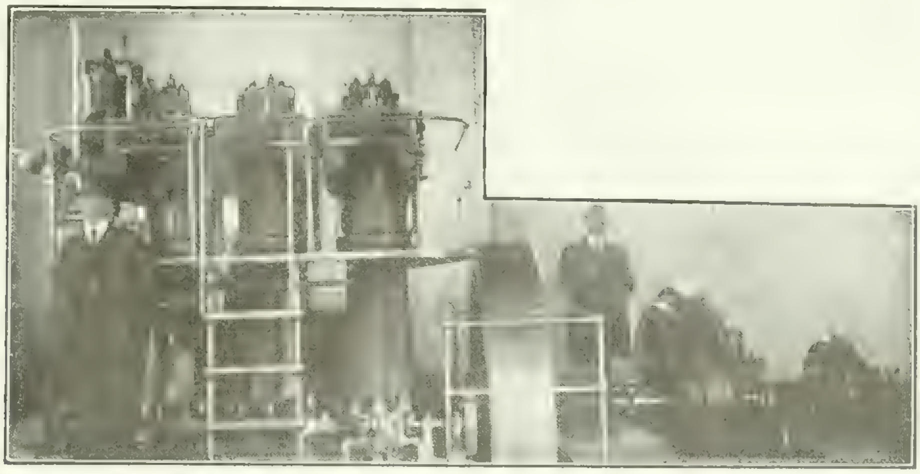

Fig. 2—Diesel Engine with Direct-connected Generator and Exciter, Melfort Power House.

Pressure is maintained on the town mains by a compressed air system, the pressure being obtained by means of compressed air instead of by actual head of water in a standpipe. In the power house are situated

20-h.p. motor. The compressor is capable of displacing 80 cu. ft. of free air per min. against a pressure of 100 pds. per sq. in. The power house arrangement is shown in Fig. 3.

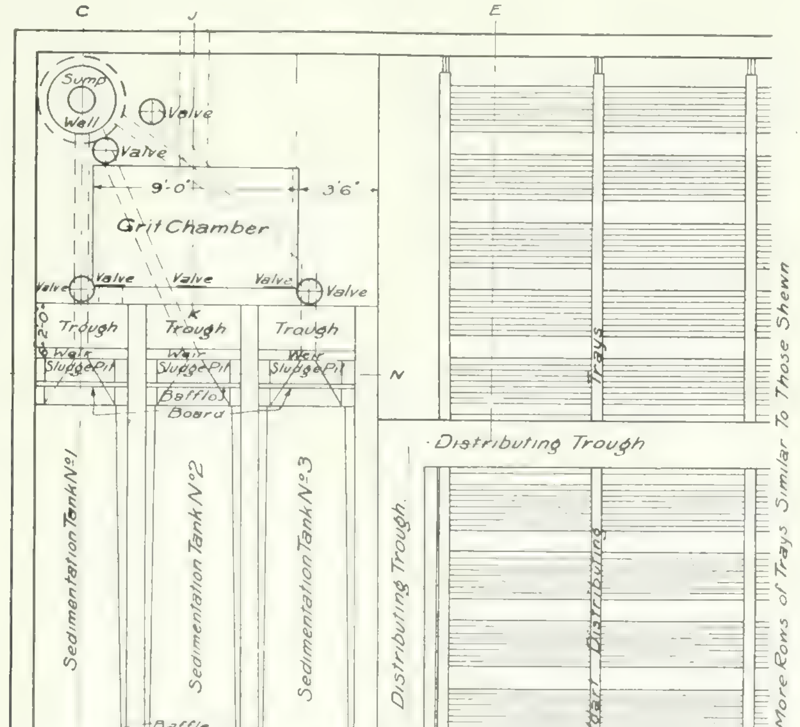

Fig. 5.—Plan of Part of Disposal Works Showing General Arrangement.

on suitable foundations, with major axes horizontal, two cylindrical steel pressure tanks, each 35 ft. long by 8 ft. in diameter. Two 3-stage, horizontal turbine pumps,

Valves are so located that either or both pumps may deliver to either or both pressure tanks or directly into the town mains. Or, the pumps may be shut down and

by using the air compressor any desired pressure up to 125 pds. per sq. in. may be maintained in the tanks and town mains till the last drop of water has left the power house.

Weldless steel water pipe is used throughout, averaging about 20 ft. per length.

Sewer System.—The sewer system (which operates by gravity) is purely sanitary, no storm water having access. At all dead ends of lateral sewers, Miller flush tanks were placed. Some of the grades were so low, owing to the level nature of the ground, that this was deemed advisable as a precautionary method.

Lateral sewers, 8 in. and 12 in. in diameter, discharge into a 15-in. trunk sewer, which runs along the main street in a northerly direction for approximately ¾ of a mile and then turns east for ½ mile toward the disposal works. Fig. 4 shows a Parsons digging machine at work on the sewer trench, excavating to a depth of 20 ft. with a width of 3 ft.

The Disposal Works.—Sewage enters a grit chamber 9 ft. x 5 ft. 4 in. From the grit chamber the sewage is discharged through three valves into distributing troughs which feed three sedimentation tanks, each 18 ft. long x 4 ft. wide x 4.5 ft. average depth. Any one of these three units may be shut down for cleaning purposes without interfering with the continuous operation of the plant.

Sludge valves placed at the low end of the sedimentation chamber permit of the sludge being drawn off into a sump well. From this it is pumped by a hand-operated sludge pump into wheel-barrows.

After sedimentation the effluent from the tanks flows over a weir into a distributing trough, which feeds a trickling filter-bed by means of Stoddart trays. The filtering material used is screened gravel, averaging 5 ft. 25 in. in depth over the filter-bed.

The method of under-draining the filter-bed is very simple. The entire floor slopes toward the centre and towards the manhole at the outlet end. Half-tile were laid with open joints down the centre and coarse stone piled around them. Figs. 5 and 6 show a half plan and details of design of the plant.

From the outlet manhole the clarified liquor is discharged into a stream 300 ft. distant. A by-pass was constructed so that in case of emergency the raw sewage might be discharged directly into the stream. The discharge of unclarified sewage into the stream would, of course, be very undesirable, and it is not expected that this auxiliary outlet will ever be brought into use.

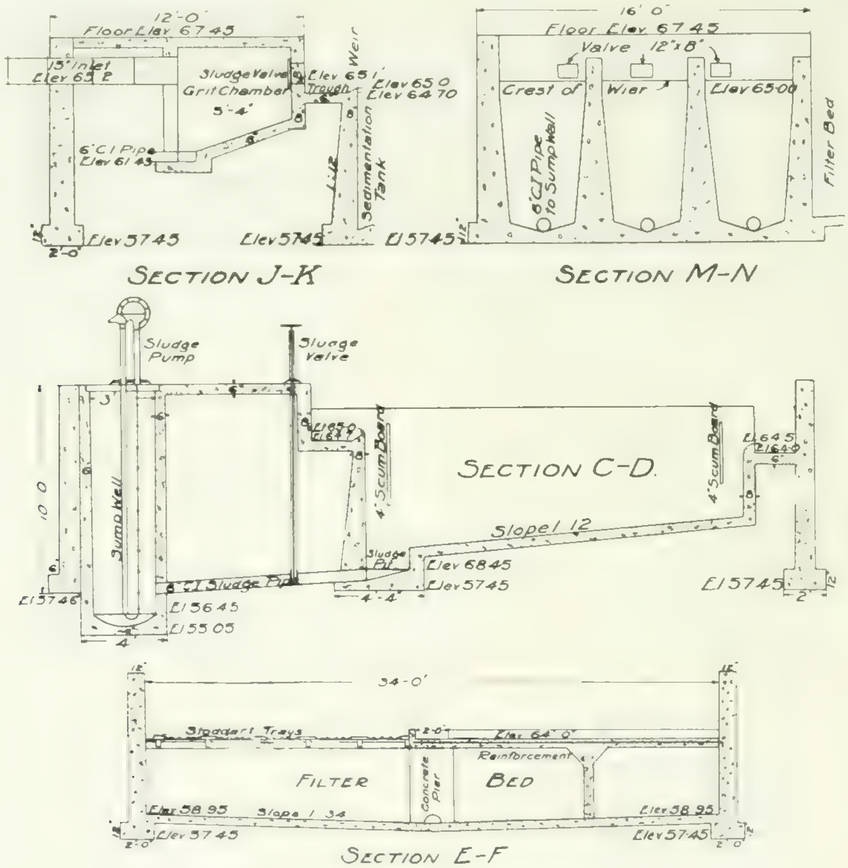

Fig. 6.—Details of Disposal Works of Melfort, Sask.

The disposal works are entirely enclosed by a frame building with a corrugated iron roof.

Similar systems have been installed and are being successfully operated in Yorkton and other Western towns, while contracts have been let and work is being proceeded with in Le Pas, Man., and Sutherland, Sask.

Memoranda has been issued by the Imperial Trade Commission of London, England, which has been prepared by Lord Pirrie and Sir John Biles, on the economic size and speed of steamers, and on the development of harbors from the point of view of ship-owners and builders. It is stated that the effect of the deepening of the Suez Canal and of the capacity of the Panama Canal on the development of harbors, will be the building of vessels of the maximum dimensions, capable of passing through the canals, and a resultant demand for an increase in the depth of harbors. He states that the minimum depth now desired for a first-class harbor is 40 feet, and suggests that, in view of the time required to obtain results, engineers should recommend 45 feet.

CONTENTS OF THIS ISSUE.

ESTIMATE vs. TENDER ON CIVIC WORK OPEN TO CONTRACT.

The practice of a city engineering department competing with contractors on public works is beneficial in that it acts as a preventative against a possible agreement among contractors in the matter of prices or conditions of work. It also acts as a stimulus to the engineering staff. This factor is important, as shown in last week's issue, in connection with some remarks on the much-discussed subject of contract versus day labor in municipal work. Obviously such competitive tendering saves money by keeping the staff more efficient and by keeping low the price of general construction work.

But in few cities is the engineering department so well developed that it can better carry out such work (with the exception, perhaps, of extensions to water mains, sewers, pavements, etc.) and at a lower cost than the responsible contractors who bid for it are invariably in a position to do. The situation is almost always the reverse. Questions of plant, labor, and experience are in favor of the contractor, and the city engineer is at a disadvantage, too, owing to inelasticity of organization. The question then arises as to the advisability of a tender from the city engineering department on work to which the above conditions apply. If it be the lowest it ought to be accepted under this competitive plan. But if the engineer's tender is to be used merely for purposes of comparison, is not the some object attained by his submitting an estimate?

The value of a city engineer's cost record of day-labor work is often questioned by contractors, and perhaps rightly so. It does not always contain such items as overhead charges, light, office rent, insurance, etc. In addition it is claimed that the engineer has many opportunities for so distributing his charges as to make the final cost of a particular work amount to any figure he desires, within a reasonable latitude.

Providing the city engineer completes the work at a figure under the bid, he may not lay claim to the profits, nor may he lay aside a part or all of such profits to cover the cost of maintenance during a guarantee period; despite the fact that the competing contractors included in their bids an estimate of maintenance for this period—an amount varying with the traffic, up to ⅓ or more of the actual cost, and properly a maintenance charge.

Again, if the work costs more than the engineer's tender the corporation pays for it, and the result is an overexpenditure of the by-law providing the funds for the Local Improvement. This occasions complaints of mismanagement from ratepayers. But, if the contractor underestimates the cost of his work, the contract price holds good, and he is the loser.

There appear to be many important works, concerning which an estimate, conscientiously worked out by the engineer, answers the same purpose as a competitive tender, and leaves to contractors the tendering for work which they are better equipped to do than is the city engineering department. Naturally, the discontinuance of tendering on all such work would not be advisable as the beneficial effect in the matter of stimulus to the engineering staff would be offset. But, a judicious combination of the two would tend to lessen the arduousness and responsibility and to add to the efficiency of the city engineer's department, without losing the advantage of being able to check contract prices.

PUBLIC TALK ON WATER SUPPLY.

A course of open lectures is being given by Dr. T. A. Starkey at McGill University, Montreal, on the principles of public health. His lecture last week dealt with surface waters, as found in brooks, rivers and lakes, pointing out the difficulty of protecting such sources from pollution. He explained in a thoroughly non-technical way the processes of purification and disinfection, claiming both as necessary factors in a community bordering on water that has any connection with a source of supply. The danger in the use of untreated waters even by municipalities where the supply is collected upon high levels and is, therefore, generally pure and admittedly suitable for domestic use, was instanced by two examples. One was a lake of very pure water which was polluted from a farmhouse, causing 400 cases of typhoid in a town of some 10,000 inhabitants. Another was the well-known case of the town of Plymouth, on the Susquehanna River, where a single typhoid case infected the water supply and caused 1,500 cases, many fatal, in a population of 8,000 or 9,000. Contamination was too lightly thought of in many of our localities.

Dr. Starkey emphasized the fact that there were well-established processes of filtration and disinfection, for the complete removal of bacteria. In the matter of sewage disposal, also, the effluent could be so treated that it would be devoid of offensive properties. Concerning filtration, he described the slow sand and rapid mechanical types of filters as to their construction and mode of operation. He fully explained the important function of the coagulant in the efficient removal of bacteria.

Chlorination was recommended to be used only in emergency cases and not as permanent practice. In such disinfection the necessity of careful regulation was advanced, as the chlorine was disposed to attack whatever other organic matter the water might contain before acting upon the bacteria. It was essential that the mixing should be thorough to avoid patchy disinfection. The process was liable to seriously impair the supply as to taste and smell, as well as to effect the skin of the user.

The outstanding features of Dr. Starkey's lecture are mentioned to show the value of lectures of this nature to the general public. As a work that should be taken up in every city and town its importance cannot be overestimated. The findings of the International Waterways Commission, in the matter of pollution of boundary waters will soon be officially made public. As Canada becomes more thickly populated the waters will carry greater volumes of impurities. Every effort should be made to acquaint the public that the serious side of the water supply question is that pertaining to healthfulness. The practice of drawing raw supply from above the municipality and emptying untreated sewage below it must be discontinued. Progress in the right direction is too slow, but it is largely because there is a general lack of knowledge of conditions and of familiarity with the available means of remedying them.

EDITORIAL COMMENT.

An amendment carried in the Quebec Legislature recently altering the paving law of Montreal to the effect that the majority vote of the whole city council, rather than the board of control, will now decide whether the property owners are to pay a share of the cost of street pavements.

LETTER TO THE EDITOR.

Sir,—My attention has been directed to the various articles upon fixed carbon which have appeared in your magazine, and also the discussion of these articles given by Mr. Law in your issue of January 15th.

In summing up the points brought out in this discussion, it appears that the main objection to the fixed carbon test is based upon the difficulty of obtaining concordant results in various laboratories, and to the uncertainty regarding the values determined on this account. Also, it is urged that the test has no real significance, and is of no scientific value. It is further urged by several writers that the fixed carbon test has been stolen from fuel chemistry and is consequently objectionable and discreditable.

The statement given by Mr. Law, with reference to the first argument is admittedly true, and the results indicated by him as obtained from various laboratories are quite interesting, but not illuminating without information as to the manipulation employed. This objection, however, is well made, but it is not a valid one if there is any intrinsic merit in the test. As pointed out by Mr. Pullar, various other tests made in connection with the paving industry are subject to similar variation in the hands of different operators, and the consistent elimination of all such tests which do give variable results, would leave very little of value in the technical routine of asphalt examination.The writer, for example, has observed analyses of the same sample of asphalt by equally reputable operators in which the penetration at 32° F. has varied 25 per cent.; at 77° F., 20 per cent.; volatilization loss varying 100 per cent., and penetration loss 112 per cent. Yet these same chemists in different cities checked each other on fixed carbon determinations within one-tenth of one per cent. Again, variations in ductility tests exceeding 30% have been observed under like conditions. Surely, Mr. Law's reasoning is equally applicable to the above tests, and if he is correct, all of these should be discarded and discredited without further question. The contention along these lines indicates rather the necessity for more closely standardizing the method of making fixed carbon tests rather than the necessity for its elimination. While this has been done by the Committee on Coal Analysis of the American Chemical Society, even their procedure requires more careful description and standardization of details than is given. Aside from this, the writer has observed on many occasions that even the standard method is not followed, or is very loosely followed by chemists making fixed carbon determinations, and in this connection, the method quoted by Mr. Law is a very pertinent example of the looseness of manipulation which tends to give these variable results.

An instance has come under the writer's observation in which this disregard of standard procedure has gone so far as to include the use of a porcelain crucible, with, needless to say, correspondingly curious results. It would therefore seem reasonable to advocate primarily that the test be more closely standardized before its elimination on this account be held desirable.

With reference to the significance of the test, the writer has attempted, in a preceding article, to determine just what it indicates—and the practical observations of Mr. Pullar are quite in line with those of the writer, and in accord with the experimental data presented in the article referred to. If this data is correct,

it is apparent that the test has some significance if uniform results can be obtained, and if such results are properly interpreted. On the other hand, if the data be not correct, it will appear that the test is useless. So far, the opponents of the test have brought forward no proof as to its significance, but have confined themselves to unsupported statements in this direction.

Reference to the origin of this test in the fuel industry as an argument against its application in the asphalt industry, is hardly worthy of discussion. Many tests are used in one industry which may be perfectly properly employed in another, and the general application of the above reasoning to the field of analytical chemistry in general, would serve to indicate the unreasonableness of this contention. This does not merit further discussion.

While those who favor the retention of a fixed carbon requirement admit the necessity of closer standardization, their position is based upon the belief that the test, when properly applied, has merit. This necessity for standardization applies not only to the fixed carbon test, but to other tests of recognized merit, which, as pointed out by Mr. Pullar, give variable results. Assuming, then, that the test will be capable of closer standardization, the question arises as to how the requirement is to be incorporated into specifications in such a manner as to prove effective, and at the same time fair to the producer and consumer. This means that requirements should not only admit good materials, but should uphold a standard which will bar from equal competition, those materials which are of lesser quality than the highest grade. This should not resolve itself into a matter of opening wide the specifications in the effort to modify the requirements to meet any certain product.

The suggestion of Mr. Pullar, with reference to different limits for various classes of asphalts is objectionable in creating arbitrary distinctions, and is fully open to the criticism brought by Mr. Law, involving dangerous precedent, and is a step in the direction of complicating rather than simplifying the basis of quality competition. The suggestion of the writer in the previous article based upon a formula involving the character of crude and percentage of yield, was given as a scientific statement of the requirement verified by laboratory research, which would obviate the necessity of classifying these materials or establishing a maximum fixed carbon limit, and would likewise provide the necessary variation for various consistencies. As stated in this article, the application of the requirement given, involves knowledge of the two above factors, fixed carbon in crude and yield of asphalt, for effective application. Mr. Law objects to this requirement on the ground that the inspecting chemist will be without means of verification of these factors. This, of course, does not follow when the material is subject to refinery inspection. Under such conditions these factors will be readily obtained by the inspecting chemist. As previously stated, difficulties arise when no refinery inspection is maintained, for it becomes necessary for the chemist to obtain his data on laboratory runs of the crude from which the product in question is made. Possibly a laboratory run will not exactly represent manufacturing figures, and it is not necessary that it should, for if carefully carried out, such trial does give the minimum theoretical fixed carbon value characteristic of a given penetration under ideal refining conditions. This statement is made as the result of many trials and comparisons. In view of the above, the variations in manufacturing figures become immaterial under the same method of operation.

It is admitted that in the absence of refinery inspection this latter operation can only establish standards for a given product made uniformly from the same crude. As indicated previously, this method is subject to the ability of the inspecting chemist to obtain, in the laboratory, the data necessary. While it is perfectly feasible to obtain this in the manner described, there are still some objections which might be properly urged. In examining a large number of samples, such as are often submitted with bids, the work of preparing fixed carbon standards for a number of different materials would be particularly laborious. Again, the determination of quality, based upon anything but the character of the finished product is not in accord with the most progressive ideas in specifications. The introduction of the clause referred to, would sift itself down to the judgment of the engineer or inspecting chemist as to his ability or his facilities for effective application of a requirement based upon these conditions. This applies only in the absence of refinery inspection, for, where the material is inspected at the plant, the writer can see no other reasonable objection to the suggested requirement.

The following alternative clause is suggested which is more readily capable of application. It does not possess, however, the scientific basis, nor can it take into account the necessary variation of fixed carbon with consistency, as does the previous requirement. As here stated, it would apply generally to paving cements of the usual consistency.

"The asphaltic cement considered apart from its native non-bituminous matter, shall be soluble in cold carbon tetra chloride to the extent of 98.5%, and shall yield upon ignition not more than 13% of fixed carbon, unless the solubility in the above solvent is increased by .2% over 98.5% for each one per cent. of fixed carbon in excess of 13%."

This, in reality, embraces two requirements which ordinarily are written separately. If the engineer or chemist has no faith in the carbon tetra chloride test (which is another much discussed question), this solvent might be replaced by carbon disulphide or any other solvent which he might consider effective in indicating the products of decomposition.

The theory of the above requirement is that products normally high in fixed carbon due to the nature of the crude, when properly prepared, will contain no insoluble matter. In effect, it places the burden of proof on these products by requiring them to show freedom from those insoluble constituents which may result from the conditions before mentioned. Likewise, materials prepared from low fixed carbon crudes will be limited to lower figures, more nearly normal than has usually been heretofore considered acceptable.

The above is suggested as an alternative to the requirement outlined in the previous article, and is given with a view of placing upon a reasonably equal basis all materials prepared from both low and high fixed carbon crudes. Either requirement in a specification retains, for the use of the inspecting chemist, a test which, when properly applied and interpreted, is quick to determine relative qualities in materials of the respective class referred to.

L. KIRSCHBRAUN.

Chicago, Ill., January 17th, 1914.

CANADIAN SOCIETY OF CIVIL ENGINEERS

ABSTRACT OF REPORT OF COUNCIL FOR THE YEAR 1913—TWENTY-EIGHT HUNDRED MEMBERS ON ROLL — TENDENCY TOWARD PROGRESSIVE WORK REFLECTED BY REPORT — FINANCIAL POSITION GOOD

The Council presents the following report on the work of the Society during the past year:

ROLL OF THE SOCIETY.

The elections took place as follows:—Thirty Members, fifty-four Associate Members, one Associate, forty-five Juniors and one hundred and thirty-five Students.

Twenty-six Associate Members were transferred to the class of Member, eleven Juniors were transferred to the class of Associate Member, one hundred and twenty Students were transferred to the class of Associate Member, eighty-three Students were transferred to the class of Junior and two Students to the class of Associate.

Seventeen deaths have been reported: one Honorary Member, nine Members, three Associate Members, one Junior and three Students. There have been removed from the rolls by resignation and on account of non-payment of dues, or on account of failure to apply for transfer to an appropriate grade: Three Members, five Associate Members, one Associate, one Junior and four hundred and thirty-seven Students.

At present the membership stands as follows:—

Hon. Members	12
Members	622
Associate Members	1,313
Associates	40
Juniors	262
Students	545
Total	2,794

The large number of Students noted above as having been removed was the outcome of the circular issued in January, 1913, calling attention to the limitations of Student membership and notifying all concerned that unless application were made for transfer to a higher grade their names would be removed from the rolls.

The seventeen members who have been removed from the rolls of the Society by death are the following:—

Hon. Member	Sir William H. White, K.C.B., F.R.S.
Members	P. Alex. Peterson (Past President)
	Peter S. Archibald (Member of Council)
	Adolphus Bonzano
	Alfred Brittain
	George Blinn Francis
	Albert George Macfarlane
	James Ross
	Wilfrid Theodore Skaife
	William Johnston Sproule
Associate Members	Edward Jodoin
	Lambert Lynn
	Russell D. Willson
Junior	James Melville Robertson
Students	Norman Wesley Brownell
	Harold Franklin Cole
	Paul E. Poitras

The resignations in practically all cases have been due to the fact that the gentlemen in question have ceased to be actively engaged in engineering work.

ANNUAL MEETING.

The twenty-seventh Annual Meeting was held at 413 Dorchester Street West, Montreal, in January, 1913, under the presidency of Mr. W. F. Tye.

The first session was called to order on Tuesday, January 28th, at 10.30 a.m., and the meeting was adjourned on Thursday afternoon, January 30th.

MEETINGS.

The Council has held seventeen meetings during the year. There have been four sectional meetings and seven monthly meetings of the Society.

The following papers and addresses were presented:

Monthly Meetings:

"Street and Railway Track Paving with Asphalt Block in a Suburban Town," by Mr. Frank Chappell, A.M.Can.Soc.C.E.

"Trusses without Diagonals in Reinforced Concrete," by Mr. V. J. Elmont, A.M.Can.Soc.C.E.

"The Projection and Survey of the 141st Meridian Boundary Line," by Mr. D. H. Nelles, A.M.Can.Soc.C.E.

"Results of an Investigation by the Dominion Government on the Coals of Canada from an Economic Standpoint," by Dr. J. B. Porter, M.Can.Soc.C.E.

"Elevator Construction," by Mr. Jas. Spelman, M.Can.Soc.C.E.

"The Toronto Water Filtration Plant," by Mr. F. F. Longley, A.M.Can.Soc.C.E.

"The Engineering Problem of Electrification," by Mr. A. H. Armstrong, M.Am.Inst.E.E.

Electrical Section:

"Electrification of a Reversing Mill at the Algoma Steel Company," by Mr. B. T. McCormick, A.M.Can.Soc.C.E. (Joint Meeting of Electrical and Mechanical Sections.)

"The Use of Synchronous Condensers with Transmission Lines," by Mr. H. B. Dwight, A.M.Can.Soc.C.E.

Mechanical Section:

"Present Practice in Design and Construction of Hydraulic Turbines," by Mr. H. B. Taylor, M.Am.Soc.M.E.

Mining Section:

"The Outlook for Mining in British Columbia," by Mr. C. E. Cartwright, M.Can.Soc.C.E.

"Initial Proceedings in Opening up a Coal Mine," by Mr. C. M. Odell, M.Can.Soc.C.E.

BRANCH SOCIETIES.

The several Branches of the Society, their Headquarters and Officers at this date are as follows:—

Victoria —Headquarters, 534 Broughton Street., (Address P.O. Box 1290.)
Chairman, F. C. Gamble.
Sec.-Treas., R. W. Macintyre.

Vancouver—Headquarters, McGill University College.
Chairman, G. R. G. Conway.
Sec.-Treas., J. R. Grant.

Calgary —Headquarters. (Address Drawer V.)
Chairman, H. B. Muckleston.
Sec.-Treas., P. M. Sauder.

Manitoba —Headquarters, University of Manitoba, Winnipeg.
Chairman, E. E. Brydone-Jack.
Sec.-Treas., G. E. Bell.

Toronto —Headquarters, Engineers' Club, King St. West.
Chairman, E. A. James.
Sec.-Treas., A. B. Garrow.

Kingston —Headquarters, School of Mines.
Chairman, A. K. Kirkpatrick.
Sec.-Treas., L. W. Gill.

Ottawa —Headquarters, 177 Sparks Street.
Chairman, G. A. Mountain.
Sec.-Treas., A. B. Lambe.

Quebec —Headquarters, City Hall.
Chairman, A. R. Decary.
Sec.-Treas., A. Amos.

COMMITTEES.

The following have been the Committees of Council during the year:—

Library and House Committee:

F. P. Shearwood, Chairman. R. J. Durley.
J. M. Robertson. H. R. Safford. A. Stansfield.

Finance Committee:

C. N. Monsarrat, Chairman. G. H. Duggan.
W. J. Francis. H. Holgate. E. Marceau.

The Czowski Medal Committee:

G. A. Mountain, Chairman. E. E. Brydone-Jack.
W. J. Stewart. A. E. Doucet. J. Galbraith.

OFFICERS OF SECTIONS.

General:

C. N. Monsarrat, Chairman. W. J. Francis, Vice-Chairman.

Electrical:

R. M. Wilson, Chairman. J. C. Smith, Vice-Chairman.

Mechanical:

H. H. Vaughan, Chairman. H. M. Jaquays, Vice-Chairman.

Mining:

J. B. Porter, Chairman. H. P. DePencier, Vice-Chairman.

Committee on Publications:

G. H. Duggan, Chairman. R. J. Durley, Secretary.
H. P. DePencier. J. M. R. Fairbairn. L. A. Herdt.

Committee on Meetings:

C. N. Monsarrat, Chairman.

The officers of Sections together with the Chairman and Vice-Chairman of Branches.

The Board of Examiners for admission of candidates under by-laws 8 and 9 is as follows:—

H. M. MacKay, Chairman. A. Surveyer, Secretary.
R. S. Lea. H. M. Jaquays. H. P. DePencier.
A. M. Gray. P. E. Mercier. J. Flahault.
M. Beullac.

The following have been the Committees of the Society during the year:—

The Nominating Committee for Officers and Members of Council for the year 1914:

H. M. Jaquays, Chairman, representing District No. 1.
H. N. Ruttan,
C. H. Rust, } Past Presidents.
W. F. Tye,
F. W. W. Doane, representing District No. 2.
F. X. A. Leofred, " " " 3.
Jas. White, " " " 4.
J. G. Sing, " " " 5.
W. L. MacKenzie, " " " 6.
L. G. Robinson, " " " 7.

Cement Specifications:

J. A. Jamieson, Chairman. C. H. Rust.
D. MacPherson. C. E. W. Dodwell. W. P. Anderson.
F. P. Gutelius. J. S. Dennis. H. Holgate.

Improved Engineering Service:

H. Holgate, Chairman. A. W. Campbell.
J. A. Jamieson. F. L. Wanklyn. G. J. Desbarats.
A. St. Laurent. L. A. Vallee. H. J. Lamb.

Establishment of Testing Laboratories:

C. H. Keefer, Chairman. J. Galbraith.
H. M. MacKay. Phelps Johnson. J. A. Jamieson.
P. Gillespie. G. E. Perley. J. B. McRae.

Educational Requirements:

E. Marceau, Chairman.
W. F. Tye. J. B. Porter. R. W. Leonard.
H. Irwin. H. Holgate.

Sewage Disposal:

John Kennedy. W. Chipman. R. S. Lea.

Steel Bridge Specifications:

C. N. Monsarrat, Chairman. F. P. Shearwood.
J. G. Legrand. R. F. Uniacke. G. H. Duggan.
N. M. McLeod. H. G. Kelley. W. A. Bowden.
P. B. Motley. F. C. McMath.

Conservation:

James White, Chairman. C. R. Coutlee.
H. F. Laurence. R. McColl. R. O. Sweezey.
W. H. Breithaupt. G. A. Bayne. A. J. MacPherson.
J. S. Dennis. J. B. Hegan. C. E. W. Dodwell.
A. E. Doucet. R. S. Lea. R. W. Leonard.
E. E. Brydone-Jack. W. R. W. Parsons. John Chalmers.
T. H. Tracy. J. B. Challies. C. H. Mitchell.
Wm. McNab.

The Electro-Technical Commission:

L. A. Herdt, Chairman. O. Higman.
H. T. Barnes. L. W. Gill. W. A. Duff.
L. A. Rosebrugh. J. Kynoch. J. Murphy.
A. B. Lambe.

Rails:

H. G. Kelley, Chairman. G. A. Mountain.
J. M. R. Fairbairn.

Track, including the subjects of Fastenings, Tie Plates and Ties:

H. R. Safford, Chairman. A. C. Mackenzie.
F. P. Gutelius.

Reinforced Concrete:

W. J. Francis, Chairman. P. M. Morssen.
C. N. Monsarrat. H. M. MacKay. P. B. Motley.
E. Brown. S. Baulne. E. S. Mattice.
E. Brydone-Jack. J. Galbraith. H. Rolph.
P. Gillespie.

The awards of the Gzowski Medal and of prizes for the best students' papers will, in accordance with the practice of previous years, be announced during the meeting.

The following is a statement of elections which have taken place since the issue of Bulletin No. 9:

October 14th, 1913.

Members:

Anderson, W.	Bligh, W. G.	Duffield, H. J.
Groves, F. W.	Kimball, H. S.	Larner, C. W.
Matheson, E. G.	McCormick, R. S.	Pearce, W.
Richardson, W. F.	Swinnerton, R. W.	

Associate Members:

Begg, J. McG.	Brown, P. P.	Clemenston, N. E.
Corman, W. E.	Garbi, L., Jr.	Herren, P. H.
Joncas, J. P. P.	McLay, D. B.	Mitchell, A. K.
Perry, K. M.	Preston, F. M.	Rodger, W.
Shannon, J.	Soper, D.	Talbot-Crosbie, W. H.
Thrupp, E. C.	Wilson, J. A. G.	

Associate:

Wilson, G. R. J.

Juniors:

Broderick, C. A.	Coumans, O. F.	French, M. H.
Gibault, J. E.	Langelier, J. N.	Maltby, Q. J.
Poitras, E.	Shaw, J. B.	Worthington, A. N.

Transferred from Associate Member to Member:

Allaire, A.	Campbell, D. McD.	Haddin, J.
MacPherson, F. L.	Murphy, J.	Powell, G. G.
Rinfret, R.	Roy, R. M.	Young, C. R.

Transferred from Junior to Associate Member:

Holdcroft, J. B.	Lount, C. T.	Pequegnat, M.
Pringle, J. F.	Vallee, I. E.	

Transferred from Student to Associate Member:

Ballantyne, T. B.	Barbault, D. R.	Beach, F. K.
Beique, P. A.	Bertrand, J. E.	Brown, T. W.
Cameron, H. D.	Chevalier, P.	Copp, W. P.
Cowen, R. P.	Dunkley, J. B.	Goedike, F. B.
Hall, N. M.	Hay, N. K.	Henry, R. A. C.
Linton, A. P.	McConkey, T. C.	McMahon, J. W.
Melsted, V. J.	Mudge, R.	Powell, W. H.
Richardson, C. E.	Simard, J. W.	Smith, A. W.
Trimingham, J. H.	Waddell, N. E.	Webb, C. E.
Whitton, C. F.		

Transferred from Student to Associate:

Robertson, G. S.

Transferred from Student to Junior:

Arsenault, A.	Bacon, T. H.	Belanger, J. C.
Bell-Irving, D. P.	Brickenden, F. M.	
de Cardaillac, R. E. M. G.		Carman, H. V. St. J.
Cole, F. T.	Cowley, F. P. V.	Duggan, H. S.
Lamb, S. R.	Lapointe, E.	Lee, R. B.
MacKinnon, K. R.	McKnight, R. C.	Middleton, J. R.
Millican, A. G.	Nares, B. L.	Neilson, L. R.
Plamondon, J. A.	Spencer, R. A.	Stewart, A. D.
Street, J. C.	Tessier, J. des R.	Tooker, G. L.
Whittaker, D.		

November 11th, 1913.

Member:

Junkins, S. E.

Associate Members:

Booth, P. D. Lee, C. A. Murton, J. C.

Junior:

McLellan, R. A.

Transferred from Associate Member to Member:

Lea, W. S.

Transferred from Junior to Associate Member:

Hogarth, G. Rider, E. B.

Transferred from Student to Associate Member:

Brown, J. A.	James, E. W. McD.	Macauley, R. M.
MacDonald, J. J.	MacLennan, G. G.	

Transferred from Student to Junior:

Burnett, G. K.	Day, H. S.	Scott, O. H.
Shanks, G. L.	Wilson, LeR.	

December 9th, 1913.

Associate Members:

Busfield, J. L. Greig, J. M. M.

Juniors:

Hetherington, W. B.	Kohl, G. H.	Macrae, L. P.
Morrisey, H. F.		

Transferred from Associate Member to Member:

Angus, W. F.

Transferred from Student to Associate Member:

Benedict, E. McL.

Transferred from Student to Junior:

Dinsmore, F. L. Fraser, R. J.

GENERAL.

The Council, having appointed the officers and standing committees for the year, at once entered upon the work of carrying out the instructions of the Annual Meeting.

The various national engineering societies were communicated with and the terms upon which their publications could be procured were ascertained and the information promptly forwarded to the Branches.

The commitment *re* appointment of Committees reporting to the Society was dealt with as follows:—

The Annual Meeting re-appointed the Committees on Establishment of Testing Laboratories, Educational Requirements, International Electro-Technical Commission, Conservation and Bridge Specifications.

It was decided that it was not necessary to re-appoint the Committee on Good Roads; and the Committees on Railway Ties, Roadbed and Ballasting and on Railway Fastenings and Tie Plates were re-organized under two Committees to be called a Committee on Rails and a Committee on Track.

It was also resolved to discontinue the Committee on Transportation Routes and to memorialize the Government as to the formation of a permanent Commission. This memorial is attached hereto. In connection with this matter, Messrs. W. F. Tye, C. R. Coutlee and J. A. Jamieson were requested to contribute such information as they had collected in regard to transportation routes as papers for the Transactions of the Society.

The two Committees on Sewage Disposal and the Special Committee on the same subject have been consolidated.

Having considered the proposal to appoint a Committee on Specifications for Steel Water Pipes, it was decided that it was not desirable to name such a Committee at the present time, but that the subject should be kept before the Society by means of a paper to be read at one of its meetings. Mr. F. H. Pitcher was requested to prepare such a paper.

After conference with various members of the Society engaged in concrete construction, a Committee was appointed to draw up a specification on the subject of reinforced concrete under the Chairmanship of Mr. Walter J. Francis, Member of Council. This Committee will present a report to the Annual Meeting.

The Specifications on Roadbed and Ballasting and on Steel Railway Bridges of Fixed Spans, approved at the last Annual Meeting, have been printed and distributed to members of the Society. The Society's specifications which have now been printed and are at the disposal of the engineering profession in Canada are the following:—Portland Cement, Cast Iron Water Pipe and Special Castings, Roadbed and Ballasting, and Steel Railway Bridges of Fixed Spans.

The opinion of the Society's solicitors was sought as to the conditions under which the Society, or a Branch of the Society, could be incorporated in British Columbia. The substance of the opinion was to the effect that a body capable of exercising general supervision over matters of interest to the profession in British Columbia, consisting of members whose relations to this Society should remain unaltered, could be established under legislative enactment.

In this connection the Vancouver and Victoria Branches were requested to definitely formulate the action they desired the Council to take and to outline such amendments to the Society's by-laws as they considered necessary in relation to the subject.

The Victoria and Vancouver Branches, replying to the communication of the Council, submitted the following recommendations:—

(1) That the parent Society will authorize the formation of a British Columbia Section of the Canadian Society of Civil Engineers; the said Branch to be governed by the existing Charter and By-Laws, and further amendments thereto of the parent Society.

(2) That the British Columbia Section shall include all members of the Canadian Society of Civil Engineers residing in this Province.

(3) That the British Columbia Section will be granted power to report on all British Columbia applicants for admission to the Society.

(4) That no candidate living in British Columbia will be admitted without the consent of the Executive of the British Columbia Section.

(5) That the Executive of the British Columbia Section will be given permission to collect rebates of annual fees from all members of the Society in this Province, and expend the sum thus realized in connection with the expenses of the Section, paying over a just proportion thereof to the Vancouver and Victoria Branches respectively, and in the future to any other Branch that may be hereafter formed in the Province.

(6) That the Executive of the British Columbia Section will be given power to discipline members living in British Columbia.

In consideration of these recommendations the Council, at a meeting held on August 6th, resolved that Sections or Divisions of the Society might be formed on the request of a majority of the Branches in Any Province; that the existing by-laws in regard to Branches should not be changed.

except that it should be possible for any member residing outside the 25 mile limit to join a Branch and become liable for the fees payable as a Branch member, the usual portion thereof to be remitted to the Branch.

It was not considered necessary that any financial arrangements should be made under the by-laws for the upkeep of the Provincial Divisions but that they should provide for their own operating expenses.

It was further agreed that recommendations Nos. 4 and 6 were not admissible; that in regard to recommendation No. 5 all dues must continue to be paid directly to Headquarters as heretofore, rebates being made to the Branches.

The matter was referred to a Committee of Council to draft a statement for revision of the by-laws in accordance with these findings, and it was decided in pursuance of the suggestion of the Annual Meeting to call a special meeting of Council for September 20th at which to consider the necessary amendments to by-laws in connection with the foregoing and in other directions. It was further arranged that the railway, sleeping car fares and all actual expenses while on the train should be paid to non-resident members attending the meeting. Members of Council residing in cities in which there are Branches of the Society were requested to get in touch with Branches and to represent the views of members to the Council in time for consideration at the September meeting.

The special meeting referred to was attended by the following Members of Council:—Mr. Phelps Johnson, President, in the Chair; Mr. W. F. Tye, Past President; Messrs. F. C. Gamble and H. H. Vaughan, Vice-Presidents; and Messrs. W. D. Baillairgé, E. Marceau, J. C. Kennedy, C. N. Monsarrat, C. H. Duggan, J. M. R. Fairbairn, R. J. Durley, A. F. Stewart, F. A. Bowman, H. E. T. Haultain, W. J. Francis, S. J. Chapleau and the Secretary. Two sessions were held and the proposals in regard to amendments to by-laws now before the membership were approved.

At a subsequent meeting of Council the proposals of the B.C. members, which are now also before the membership, were received and it was considered desirable to issue the circular letter attached to the proposed amendments to by-laws in explanation of them.

The place of holding the Annual Meeting has this year received more than usual attention in view of the fact that the British Columbia Branches extended a cordial invitation to the Society to hold the meeting in Victoria. The opinion of the membership was sought, and as a result of the postal card notice sent out some 700 replies were received, indicating a majority in favor of the meeting in British Columbia. Resolutions regarding the place of meeting were received from some of the Branches and expressions of opinion from non-resident Councillors and other members of the Society.

After a very full consideration the following resolution was adopted:—

> "That in view of the strong desire expressed by many of the members and Branches of the Society to hold a meeting in British Columbia in 1915, on account of the Panama Exposition to be held at that time and the opening of two transcontinental lines, and considering the impossibility of holding a meeting on the Pacific Coast in two successive years, it was decided that the meeting of 1914 should be held in Montreal."

This decision of the Council has been approved by the Executive of the Victoria Branch.

The Council desires to call the attention of the Meeting to the fact that the by-laws of the Society do not specify the place of holding the Annual Meeting, and suggests the desirability of an amendment in that regard.

The importance of holding meetings in the various cities of Canada is fully recognized and the Council, having given some thought to the subject, is of opinion that these meetings should take the form of a Summer Convention, the annual business meeting of the Society being held at Headquarters.

In the opinion of Council it would be well that the practice of holding one meeting of Council during the year, at which members from all parts of Canada could be present, should be established, and possibly such gathering might occur in connection with a summer convention.

In furtherance of the resolution adopted by the Annual Meeting regarding stream measurements, Mr. James White, Assistant to the Chairman of the Commission on Conservation, was asked to gather together all results of measurements made under the direction of the Dominion and Provincial Governments and to have the same published under the auspices of the Commission. Mr. White was kind enough to undertake this work should time permit.

The matter of improving the library facilities was undertaken in connection with the Library Committee with the result announced in the report of that Committee.

The Council has pleasure in reporting that in accordance with the suggestion of the last Annual Meeting a Junior Section of the Society has been formed. This Section has held several meetings during the year. Its officers at present are as follows:—

A. J. Kelly, Chairman.	W. Clerk.
J. H. Norris.	B. O. Smith.
R. M. Walker.	

The Council reports the appointment of Mr. H. G. Kelley to fill the vacancy created by the death of Mr. J. M. Shanly at the close of the year 1912.

The vacancy created by the death of Mr. P. S. Archibald, which occurred on March 16th last, was not filled.

The Society has been represented at various gatherings during the year, amongst which may be noted the ceremony in connection with the placing of the window in Westminster Abbey in memory of the late Lord Kelvin, which ceremony was attended by Mr. W. F. Tye, Past President of the Society. Mr. H. J. Bowman represented the Society at an International Road Congress in London, of which the Society has now become a member. The Society was also represented at the Western Canadian Irrigation Convention by Messrs. H. B. Muckleston, F. H. Peters and P. M. Sauder.

The Council desires to call the attention of members to the importance of a more general response to the request accompanying the preliminary notice of applicants for admission and transfer—viz., that members are invited to report any facts which may affect the classification and election of any of the candidates and, where the professional career of applicants is known, they are specially invited to make a definite recommendation as to classification. It is regretted that this invitation has not been generally accepted and that as a result classifications have been made which have subsequently given rise to criticism.

The financial statement presented herewith shows the total cost of the Society's building, which it is satisfactory to note is within the appropriation for the purpose and substantially in accord with the report made to the Society last year.

The Council desires to record its satisfaction at the interchange of courtesies through the Ottawa Branch with the American Society of Civil Engineers at its Convention in Ottawa in June last. This Convention was attended by a number of members of the Society who appreciated the hospitalities extended by their Ottawa brethren and the officers and members of the American Society of Civil Engineers.

Attention is called to the fact that a Branch of the Society has been established in Calgary under the Chairmanship of Mr. H. B. Muckleston. The branches of the Society now number eight, in accordance with the list published on another page.

The attention of Council has been called to the establishment, or proposed establishment, of a Society of Municipal Engineers in Regina, and it has been reported that this Society proposes to seek exclusive legislation from the several Provincial Governments. The matter is being investigated by the Council.

Two volumes of *Transactions* were published and distributed during the year—namely, Volume II. for 1912 and Volume I. for 1913. Bulletin No. 9, giving lists of members elected between the date of the last Annual Meeting and July 1st, additions to the Library and general notes of the Society's affairs, was issued during the month of August.

The Council regrets that up to this date it has not been possible to obtain reports from all of the Committees for submission to the membership. Such reports as were in hand at the end of the year have been printed for distribution in advance of the Annual Meeting.

Acting on a suggestion at the Annual Meeting, the Council has, as already noted, made the attached representations to the Dominion Government with reference to the problem of transportation routes.

PHELPS JOHNSON, President.
C. H. McLEOD, Secretary.

Montreal, January 14th, 1914.

Your Memorialists have the honor to submit for the consideration of the Government of Canada, that the time is now opportune to appoint a Royal Commission on Transportation and allied problems.

The early opening of the Panama Canal and the great development in all lines of industry from one end of Canada to the other, raise questions demanding the most careful solution.

---

(1) The report of the Transportation Commission made in 1908 contains a great deal of valuable data, but is now largely obsolete.

(2) That such a Commission should consist of seven members—viz., one Railway Engineer, one Hydraulic Engineer, one Railway Manager, a Lawyer, a Transportation Manager familiar with Lake and Ocean Navigation, two eminent business men, one from the East, one from the West, and a secretary.

(3) That such report should include and, whenever possible, make recommendation on the following matters:—

(a) Water Routes.—River improvement, lake and gulf dealing with existing systems—proposed systems from the commercial and engineering sides, harbors, docks, graving docks, types of ships and barges for inland service.

(b) Winter and Other Ports.—National and local, required facilities and equipment having regard to the handling of grain, merchandise, manufactures, coal and the other heavy bulk products to the end that the most economical method be secured.

(4) There is a necessity for an even, steady movement of traffic throughout the year. How may this be accomplished at the least possible cost to the people of Canada?

(5) The water power possibilities, as an incident of navigation on the St. Lawrence, Ottawa, and other important rivers. It is believed by competent men that the St. Lawrence may be converted into slack water navigation from Montreal to Lake Ontario by the building of about five dams and five ship canal locks, and that as an incident thereto, several million horsepower of energy may be had at very low cost. Such a possibility suggests a development in manufacturing of incalculable value to the country and would seem worthy of special report.

The existing canal system on the St. Lawrence is expensive to maintain and operate. The suggested system would seem to offer an opportunity for large savings in both respects.

(6) Railways:—

(a) Existing Railways.—In what respect is it possible to improve, having regard to terminals, receiving and delivering freight in large cities and at other important points? How may transportation be rendered more economical?

(b) What should be the policy of the country regarding new railways? What conditions should be made on behalf of the public?

(c) Earnings and Expenses.—A reasonable definition of what they should be.

(d) Competition.—To what end can it be secured?

(e) Regulation.—To what extent should it extend in order that capital may be secured for the continued requirements of the country and the public be sufficiently protected?

(7) Routes and Outlets:—

The Atlantic Seaboard.
The Pacific Seaboard.
The Hudson Bay.
The Great Lakes

(8) Your Memorialists, the Canadian Society of Civil Engineers, represent practically every qualified engineer in Canada. It is with a knowledge of the importance of the subject and of how easily great mistakes, causing enormous waste of money, can be made, that your Memorialists have approached the subject, in the hope that your honorable body may see fit to grant such a Royal Commission to the end that our common country may be benefited.

(Signed) PHELPS JOHNSON, President.
C. H. McLEOD, Secretary.

Montreal, December 1, 1913

REPORT OF THE LIBRARY AND HOUSE COMMITTEE.

The Library Committee reported on January 10th, 1914, that they had experienced a most progressive year. Additions to the reading matter had been very extensive in the endeavor to bring it up to date in all sections. The new volumes were carefully chosen or approved by the Chairmen of the different sections and the list was supplemented by members of the Committee. The purchase of the new Encyclopædia Britannica was recommended to the incoming Council. The thanks of the Society were said to be especially due to Mrs. P. A. Peterson, who had kindly presented to the Library many volumes of engineering works which belonged to the late Mr. P. A. Peterson, Past President of the Society.

This Committee superintended the moving and setting in order of the library in its new quarters, which occasioned very extensive labor; also the furnishing of the storage and reading rooms of the new building. The Committee, of which F. P. Shearwood was Chairman, recommended some further additions to the furnishing of the rooms.

STATEMENT OF FINANCES.

The receipts of the Society for the year ending 31st December, 1913, were $646.05 in excess of the expenditures. The expenditures amounted to $21,860.85, of which $2,120.50 was on account of rebating fees to branch societies, over $6,400 on account of printing, and about $1,700 interest paid on mortgages, etc.

The receipts, which amounted to $22,506.90, were made up mainly from fees collected, which amounted to $21,386.69.

The balance sheet shows a healthy condition, the Society owning the property at 176 Mansfield Street, Montreal, valued at over $91,500, including furniture. The Society also possesses a special bank deposit receipt for $5,000, and nearly $300 other cash on hand, $6,000 worth of books, and various other assets.

The liabilities consist mainly of a $20,000 mortgage on the property, less than $4,000 being payable on account of rebates to branches, prize fund accounts, accounts payable, etc.

Special credit is due for this good financial report to the Finance Committee of Council, the Secretary of the Society and to Mr. Ernest Marceau, who has been the efficient Treasurer of the Society for the past five years.

REPORT OF BOARD OF EXAMINERS.

January 6th, 1914.

Examinations were held in May and November. The results are summarized in the following table:—

Subject.	Number of candidates presenting themselves.	Passed.	Failed.
Theory and Practice of Engineering	11	6	5
Railway Engineering	10	7	3
Municipal Engineering	5	5	0
Total	26	18	8

The candidates rejected were, as a rule, so deficient in a knowledge of the principles underlying sound engineering practice that it was impossible to regard them as qualified to "design as well as direct engineering works." The admission of such candidates, probable enough in the absence of examinations, would in the opinion of the Board tend to lower the standing of the Society.

The Board also examined and passed upon a large number of educational certificates presented by candidates claiming exemption in whole or in part from the scheduled examinations. As these certificates emanate from a great variety of institutions, their consistent appraisal is difficult. The Board has also felt somewhat embarrassed by the lack of clear definition of its duties as compared with those of the Education Committee in respect to this work. It is felt that in order to secure the best results, the examination of certificates should be in the hands of a single body preferably distinct from the Examining Board.

ARTHUR SURVEYER, Secretary.
H. M. MACKAY, Chairman.

REPORT OF COMMITTEE ON ESTABLISHMENT OF TESTING LABORATORIES.

Ottawa, Ont., Jan. 13th, 1914.

The President and Members,
Canadian Society of Civil Engineers.

Gentlemen,—

I beg to submit the following report of the Committee on Establishment of Testing Laboratories, on behalf of the Members of our Committee: Professor J. Galbraith, Past President; Professor H. M. Mackay, Professor Peter Gillespie, and Messrs. Phelps Johnson, President; J. A. Jamieson, A. St. Laurent, Geo. E. Perley, J. B. McRae, and C. H. Keefer.

As the establishment of a Government Testing Laboratory is in the hands of the Government there is little that we have been able to do, except to urge its necessity both for the Government and the public.

The Minister of Public Works, the Hon. Robert Rogers, has been interviewed and written to, and asked to place an appropriation in the estimates for testing laboratories. I wrote him, for the Committee, that the definite information acquired through testing laboratories for the use of all the Government Departments interested in Canadian structural materials would be of great practical as well as scientific value, and that should the Government follow the example in this respect of other countries, it could not fail to ultimately add to Canadian prestige in keeping abreast of the times. In answer to this letter the Hon. Robert Rogers writes, "I will be glad to do whatever I can in the matter to which you refer."

The Deputy Minister of Public Works has also been interviewed and expressed himself in sympathy with our recommendations.

Our Committee recommends that, as the establishment of a Government testing laboratory is a matter depending solely on the action the Government may see fit to take, this Committee might for the present be discontinued; but we would also strongly recommend, should this action be taken, that the Council should keep the matter before the Government by writing frequently to the Minister of Public Works, drawing attention to the importance to the country, as well as the Government, of a laboratory such as they alone would be in a position to equip and maintain, and when definite action is taken by the Government that a Committee be again appointed to assist the Government in any way desirable, should they wish the co-operation of our National Society.

Respectfully submitted,
C. H. KEEFER,
Chairman.

A proposal to give Chicago a comprehensive subway system, costing from $80,000,000 to $150,000,000, to be paid for out of the earnings of the system, has been made to the Mayor, and a committee of the Chicago City Council by Walston H. Brown, engineer of New York and J. Morton Griffiths of Griffiths and Company, London, England.

Blast furnace operators, representing practically the entire merchant pig iron industry of the United States met in New York, on January 8, and organized the American Pig Iron Association. The membership, it was announced, comprises owners of plants with a property investment of $200,000,000, and an aggregate annual capacity of 13,639,000 tons of pig iron. The discussion of manufacturing problems, the standardization of pig iron grades, the reduction of costs and the improvement of quality are among the purposes of the organization, according to the by-laws adopted.

Final designs for the lamp standards, brackets and reflectors to be used in lighting the locks of the Panama Canal have been made and have received the approval of the Fine Arts Commission. The posts, including the ornamental ball, will be of reinforced concrete, cast in iron forms, and a total of 511 standards carrying single or double arm brackets will be required. The reflectors will be placed 29 feet 6 inches above the ground, and 4 feet 3 inches from the centre of the standard. Each concrete double arm bracket with reflectors will weigh approximately 1610 lbs.; and the solid ball, weighing 730 lbs., will be used to counterbalance the weight of the single arm brackets on the middle locks.

COAST TO COAST.

Calgary, Alta.—The receipts of the Calgary electric department for 1913 were $675,000, and the expenditures, $610,000, including interest on debentures, providing for sinking fund and special depreciation.

Winnipeg, Man.—The earnings of the Winnipeg Electric Railway on actual street car operation in the city of Winnipeg for the calendar year, 1913, were $2,384,597.28, an increase of $269,604.48 over the earnings in 1912.

Banff, Alta.—It has been stated by Engineer Child, of Banff, that estimates for the expenditure of $1,000,000 in public improvements at this city during this year have been prepared, and the work is to commence in the spring.

Winnipeg, Man.—Net earnings of the city light and power company for the month of December, reached a total of $88,752.73 after making allowances for corrections and discounts, showing a net and certain profit of $23,757.

Ottawa, Ont.—The annual report of the Transcontinental Railway Commission, produced in the Dominion House of Parliament, on January 22, showed a total expenditure of $126,000,000. The amount spent last year was $14,000,000; in 1912, $20,000,000. The New Brunswick section was under operation during the year, and produced a revenue of $32,000. The cost of operation of this section was $36,000.

Winnipeg, Man.—The statement of the light and power department of Winnipeg for 1913 reports that the peak load was increased from 14,000 to 20,000 horsepower; that the gross revenue was $850,000, the cash receipts $735,000; and in general that there has been a substantial increase in the installations of transformers, meters, lamps of all kinds and ornamental lighting, as well as in the erection of poles and the stringing of wire. The balance sheet will not be submitted until the end of the fiscal year, but Manager Glassco reports that the operations for the calendar year show a large surplus over all expenditures.

Iona, N.S.—About 1½ miles from Iona Station on the line of the Intercolonial Railway, and on the shores of the Bras d'Or Lakes, will commence at once the construction of a $50,000 calcining plant for the Iona Gypsum Company. The gypsum deposit of the company is estimated to contain 25,000,000 tons of 98 per cent. plaster rock, which will be reduced and mixed on the spot, and will be shipped from the company's wharf adjacent to the property. The quarrying is all cliff face open cut. The mill will be 60 x 40; and the warehouse and mixer 60 x 40. The power house is to be 32 x 40 and fitted with a twin battery of Robb Mumford boilers and a 225 horsepower compound Corliss engine.

Port Arthur, Ont.—Early last summer was commenced the construction of Port Arthur's new intake and pumping station, which is situated about a mile from Bare Point on the shore of the bay. The new pump house is completed and will soon be equipped with machinery, titanic pumps which will take up practically the whole height of the building. For the depth of 12 feet or more the structure has been built with reinforced concrete, while the remainder is of brick. The intake well machinery will not be installed until the tunnelling has been completed; and of the 1,500 feet of length to be completed, 300 feet have now been bored. This has been accomplished by blasting through solid rock. It is expected that this part of the work will be rushed and that it will be completed about the end of April; and also, that the entire undertaking will be finished and the plant put in operation by the first of July.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

CONTENTS.

BOOK REVIEWS.

Sewer Design.—By H. N. Ogden, C.E., Professor of Sanitary Engineering, Cornell University. Published by John Wiley & Sons, New York; selling agents for Canada, Renouf Publishing Company, Montreal. 248 pages; 71 illustrations; 5 plates; size, 8vo.; cloth. Price, $2.00 net.

Reviewed by Prof. P. Gillespie.

The second edition of Ogden's "Sewer Design," like its predecessor of fifteen years ago, is essentially a text-book. The title, the reader is compelled to feel, is something of a misnomer, since much of the matter contained in the volume has to do with sewer design *per se*, indirectly rather than directly. The much-discussed matters of rainfall and run-off are treated with considerable patience and detail, while many authorities and investigators are drawn upon in the preparation of the chapters relating thereto.

The chapter on sewer cross-sections comprises some six pages only, leaving with the reader the impression that this quite important phase of the designer's problem is altogether too briefly treated. The chapter on flushing is timely, and is illustrated by a number of half-tone and zinc etchings of flush-tanks and automatic siphons, taken mainly from the descriptive literature concerning these, issued by the manufacturers. The theory of the siphon is too brief, although, indeed, this seems to be a just criticism of most modern texts on this subject. Excellent features of the book from the student's viewpoint are the working out of specific problems from actual data and the incorporation of the rules and regulations for the preparation and submission of plans for sewerage systems and disposal works, New York State Department of Health, 1912.

Electric Power Plant Engineering.—By J. Weingreen. Published by McGraw-Hill Book Company, New York. 445 pages; 309 illustrations; 15 tables; cloth; size, 6 x 9 in. Price, $5.00 net.

Reviewed by H. G. Acres,
Hydraulic Engineer, Hydro-Electric Power Commission of Ontario.

The chapters, twenty-seven in all, have the following titles: Introductory; Direct-Current Generators; Synchronous Converters; Mercury Rectifiers; Storage Batteries; Three-Wire System; Feeder Panels; Direct-Current Motors; Direct-Current Circuit-Breakers; Direct-Current Stations; Typical Electric Power Stations; Low-Tension Switching; High-Tension Switching Arrangements and Methods of Connection; Circuit Interrupting Devices; Oil Switches; Relays; Potential Regulators; Constant-Current Systems; Starting Compensators; Lightning Arresters; High-Tension Switchboards and Wiring Diagram; Cells and Compartments; Wall Outlets; Central Stations; Typical Central Stations; Substations; Typical Substations; Appendix with fifteen tables.

The scope and purpose of the book is set forth in the preface as follows: "Its object is to offer to the contractor and engineer, as well as to the student, material which will help them to understand the methods of handling electrical energy. It is assumed that the reader is familiar with the basic principles of electrical engineering, as well as with electrical machinery and ordinary instruments. The aim has been throughout to restrict theoretical discussions as much as possible and to eliminate higher mathematics. The book is intended as a useful handbook for those concerned with practical problems."

The work has been limited to American power station engineering. The material represents exclusively present-day practice, and the lines which future development may be expected to follow are pointed out.

Chapters I. to X. are devoted to direct, and the remaining seventeen chapters to alternating current, the matter being so arranged as to give special prominence to the discussion of switch-gear and control apparatus in general. The direct-current section of the book takes up the first 94 pages only. This is directly the result of limiting the scope of the work to American station practice, for in no country in the world has the development of A.C. machinery and apparatus so overshadowed that of direct current as in America.

Chapter IV. on Mercury Rectifiers is interesting, as is also Chapter V. on Storage Batteries, the latter in particular containing valuable information relative to storage battery practice in Europe.

It is to be regretted that the author did not extend the scope of the direct-current section sufficiently to include at least a general description and discussion of the Theory system of direct-current high-tension transmission, concerning which very little has been published in this country up to the present time.

The alternating current section is mainly descriptive, with much tabulated matter, amply illustrated with plates, diagrams and reproductions of dimensioned drawings. The chapters on Oil Switches, Potential Regulators and Lightning Arresters are strictly up-to-date, and constitute the most important feature of the book.

The author has adhered strictly to the intention expressed in his preface with regard to the elimination of mathematical discussion, the book being intensely practical throughout. On this account a certain amount of first-hand, practical experience is necessary for a proper appreciation of its contents. While it, therefore, lacks the theoretical element usually called for in a student's text-book, it should have a wide range of usefulness as a reference book for practising engineers and plant superintendents.

Theory of Machines and Practical Mechanisms.—By Prof. Andrew Jamieson, M. Inst. C.E. Eighth edition of Vol. V. of series on Applied Mechanics and Mechanical Engineering. Publishers, Charles Griffin & Company, Limited, London, Eng. 526 pages; illustrated; cloth; size, 6 x 9 in. Price, $2.00.

Reviewed by A. S. L. Barnes,
Hydro-Electric Power Commission of Ontario.

Among English engineers the name of Andrew Jamieson, quondam professor of engineering in the Glasgow Technical College, is as a household word, and, were the present work in only its first edition, it would be taken for granted that it was well written; an eighth edition of such a book must, therefore, speak for itself.

Intended primarily for the use of students, and of engineers qualifying for various diplomas, the book is arranged in the form of lectures, which lead the reader from loci and point paths to numerous mechanical motions, efficiency of machines, gearing, etc.

The lecture on loci and others up to lecture No. 5 describe very clearly how the position of any point, or series of points, may be definitely indicated by referring them to fixed co-ordinates, and passes on very naturally to a consideration of different types of mechanical motions and the methods of ascertaining the paths described by different points in such mechanisms in various positions.

It would hardly be thought that the word "machine" was a difficult one to define, but the author refers to another writer, who quotes as many as seventeen different definitions, to which someone else has added several more. Prof. Jamieson states that the modern theory of machines would give the following definition: "To transform natural energy into particular kinds of work by a combination of resistant bodies, whose relative motions are completely constrained." This certainly looks scientifically correct, though, no doubt, the average man would be content with something more on the lines of the schoolboy's definition of salt, viz., that "it makes potatoes taste nasty when you don't put it in."

The middle portion of the book is devoted to mechanisms applied to divers kinds of machines, such as planing and shaping machines, winches, cranes, etc., and a good deal of space is given up to the design and methods of cutting the teeth of wheels; this latter subject is very fully and clearly dealt with

The transmission of power by belting and ropes comes next in order, while the latter portion of the book discusses the inertia of moving parts of engines, crank effort diagrams and various types of engine governors.

Each of the 18 lectures is supplemented by a number of suitable questions, and the closing pages of the book contain 4 Appendices, giving the examination papers set within recent years by a number of British educational and engineering bodies, definitions of the fundamental C. G. S. Units and their mechanical and electrical derivatives; and, finally, tables of logarithms and the trigonometric functions of angles.

Not only students, but trained engineers will find this book useful if the scope of their work covers the subjects with which it deals.

Handbook for Machine Designers and Draftsmen.—By Fred. A. Halsey, B.M.E. Published by McGraw-Hill Book Company, New York City. 494 pages; illustrated; size, 9 x 12 in.; flexible leather binding. Price, $5.00 net.

Reviewed by Prof. R. W. Angus,
Department of Mechanical Engineering, University of Toronto.

The author of this book was editor of the "American Machinist" for many years, and is, therefore, competent to discuss the very important matter of machine design. His book is intended for designers and draftsmen, and, therefore, contains a very great number of tables and diagrams so as to facilitate the draftsman's work, and to save time that would otherwise be required for calculations. There are also a great number of illustrations, although the author does not appear to have considered it essential to provide an undue number of drawings of machine parts.

Almost every part of the machine has been treated in the thirty-nine sectional headings, which include such a variety of subjects as bearings, belts, flywheels, gears, brakes, bolts and nuts, balancing, boilers, engines, etc. In the arrangement of the book the usual division into chapters has been replaced by a division into sections, each beginning on a new page, and each having the numbering of tables, diagrams, formulas and cuts starting at that section, so that it will be a fairly easy matter in future to add to the work.

To give the reader an idea of the contents of the book the section on hydraulics and hydraulic machinery has been selected at random and contains the following material in addition to other matter: Diagram of the velocity of water jet and horse-power corresponding to different heads, tables of capacities of tanks, loss of head in pipes, water delivered by hydraulic rams, diagrams of pipe-flow, loss of head in fittings, thickness of hydraulic cylinders and of rams, and of the power and capacity of pumps. The section also contains many useful formulas, data on hydraulic packings and cup leathers, information on friction in stuffing boxes, and numerous illustrations of parts of machines. It is evident that the treatment is fairly complete.

The designer and draftsman will find the book of very great help, but it is very unfortunate that it could not have been made in more convenient size, as it is a book which must lie on the drafting table and in its present form it takes up considerable space and is awkward to handle.

Suspension Bridges and Cantilevers: Their Economic Proportions and Limiting Spans.—By D. B. Steinman, C.E., Ph.D., Professor of Civil Engineering at the University of Idaho. Second edition, revised. New York: D. Van Nostrand Company (Science Series). Boards; size, 3¾ x 6 in.; 185 pages; four folding plates. Price, 50 cents.

Reviewed by C. R. Young, M. Can. Soc. C.E.,
Assistant Professor of Structural Engineering in the University of Toronto.

The first edition of Professor Steinman's little book, which appeared two years ago, was welcomed as one of the clearest economic studies of long-span bridge construction which had ever been written. So carefully and thoroughly had the author done his work that in the second edition, which now appears, it was not found necessary to modify the analytical studies of the structures considered nor the results of the investigations for their economic proportions and limiting spans.

Although the original edition of the book was thoroughly reviewed in this journal, it is perhaps desirable to briefly state the principal results of Professor Steinman's studies. In order to give a reliable basis for generalizations he has designed suspension bridges of 1,500, 2,250 and 3,000 feet and cantilever bridges of 1,000, 1,500 and 2,000 feet in span, respectively. Estimates of quantities and costs are submitted, and from these and other data it is concluded that (1) the maximum practical span for suspension bridges ranges from 3,500 to 4,900 feet, depending upon the assumed live load; (2) the limiting economic span for suspension bridges is about 3,170 feet; (3) the maximum practical span for the cantilever type ranges from about 2,000 to 3,000 feet, depending upon the assumed live load; (4) the greatest span

for which the cantilever type may be profitably employed is about 2,700 feet; (5) the span of equal cost for the types is 1,670 feet.

Few changes are made in the revised edition, and these are principally in furtherance of greater clearness. The term "limiting span" is introduced as signifying the span length which each type of bridge cannot physically exceed. The longest span at which the cross-section of the principal members will not exceed an assigned maximum value, determined by the limitations of design, fabrication, transportation and erection, is then termed the "maximum span." Added usefulness is conferred on the book by bringing the bibliographies up to date and amplifying the tables of bridges noteworthy for length of span or other features of interest. Four folding plates, showing the elevations and cross-sections of suspension bridges and cantilevers from 1,000 to 3,000 feet have been inserted illustrating the designs described in the text.

The excellence of this little book should commend it to anyone having to do with the design of long-span bridges.

Reinforced Concrete Construction—Vol. II., Retaining Walls and Buildings.—By George A. Hool, S.B., Associate Professor of Structural Engineering, the University of Wisconsin. Drawings by Frank C. Thiessen, B.S., Instructor in Structural Engineering, the University of Wisconsin. New York: McGraw-Hill Book Company, Inc. 666 pages; 411 illustrations in the text and 34 full-page and folding plates; cloth; size, 6 x 9 in. Price. $5.00 net.

Reviewed by C. R. Young, M. Can. Soc. C.E.

The excellence of the previous text-books prepared for use in the Extension Division of the University of Wisconsin is fully maintained in the second volume of Professor Hool's treatise on Reinforced Concrete Construction. Although the presentation has evidently been adapted to the needs of those students who must largely depend upon their own resources, the work can scarcely be said to lose value to the practising engineer on this account. So much practical information is contained in the six hundred odd pages that a little over-elaboration of a point is easily overlooked.

The book is divided into two parts, the first dealing with retaining walls, and the second with buildings. Of the 666 pages, however, 602 pages deal with buildings, a proportion to which no exception can be taken.

Retaining walls are covered in three chapters, dealing with the theory of stability, design and construction. Little space is given to the first and third divisions of the subject, the students' problem being assumed, as it would appear from the text, to be largely centred about design. In calculating the external forces on walls, the author employs the method of equivalent fluid pressure, undoubtedly a simple method of dealing with the problem.

Under buildings, floors are given first consideration. Monolithic beam and girder construction is exhibited very thoroughly, as far as design is concerned, by a detailed design of a typical floor panel in four different ways. Full-page plates containing details of these various schemes are given, even each reinforcing rod being fully detailed. Another panel is then designed, in one-way hollow tile construction, affording an instructive comparison with the monolithic type. The flat slab system, while perhaps not given the attention which Mr. Turner might desire, is nevertheless clearly described, as far as essentials are concerned. The author is not impressed with the accuracy of Grashof's analysis, and prefers the beam method or the circular plate method. Unit construction is deservedly given some space, followed by a discussion of various details and floor attachments. Chapter V. is devoted to types of reinforcement.

Following the discussion of floors, come excellent chapters on Roofs, Columns, Foundations, Walls and Partitions and Stairs. Valuable though the information in the chapter on Elevator Shafts may be, from the fact that it chiefly concerns elevators, it appears to be somewhat out of place in a text-book on reinforced concrete construction. One of the most valuable portions of the work is that dealing with continuous beams, eccentricity of loading on columns and wind stresses. Particularly with respect to the former, the fullness of detail, characteristic of the author's method, is likely to be appreciated.

The general discussion of structural elements is then effectively illustrated by two examples of the design of entire buildings. These examples are not in detail, portions of one of the buildings having previously been discussed minutely, but the general considerations and the specifications cited are particularly useful to the designer who has previously confined his attention to parts rather than the whole.

Proceeding to construction, Materials, Forms, Bending and Placing of Reinforcements, Proportioning, Mixing and Placing of Concrete, Finishing of Surfaces and Waterproofing are adequately considered. Mr. A. W. Ransome contributes an authoritative chapter on Construction Plant, and Mr. Leslie H. Allen, of the Aberthaw Construction Company, a most useful section on Estimating. The work is concluded by the inclusion in an Appendix of the Second Report of the Joint Committee on Concrete and Reinforced Concrete.

Considered in its entirety, there is little which can be criticized in the book. It appears to be fairly free from typographical and other errors, although the reviewer might point out that the strength requirements for cement and mortar on page 444 are erroneously given as pounds per square foot instead of pounds per square inch. Broadly judged, therefore, the book must be regarded as a most useful contribution to the literature of reinforced concrete.

Cement, Concrete and Bricks.—By Alfred B. Searles, Lecturer on Brickmaking under Cantor Bequest, Consulting Ceramic Engineer, Sheffield, England. Published by Constable & Company, Limited, Leicester Square, W.C., London. 412 pages; size, 6 x 9 in.; cloth. Price, $3.00.

This book is one of a series of text-books introductory to the chemistry of the national industries, and, therefore, deals in detail with the chemistry of the materials mentioned in the title. It is descriptive rather than technical, and it is a collection of facts rather than an exposition of any new theorem. The illustrations and examples are English, and are, therefore, not as convincing to Canadians.

There are four distinct divisions in the book, the first of which deals with cements, commencing with a chapter on the raw materials and concluding with a descriptive chapter of the usual tests. The second division is called concrete, and is, like the part on cement, laboriously thorough in descriptive detail. The lines of stress in beams are shown in carefully prepared illustrations, but no mention is made of the rules which govern the shape, length, height or breadth of it. Reinforcing systems are illustrated, but nothing is said about the disposition of the steel; so that this part is not of technical value. The three chapters on bricks are the most interesting and instructive in the book, although they are not to be considered as a text on the subject. The fourth division, which consists of five pages, and which seems to have been added as an appendix, does not deal with siliceous bricks as fully as the subject deserves.

The book is well written and well indexed, making it convenient as a reference. It may be considered as a summary of the facts regarding cement, concrete and bricks without proofs or rules.

The Sampling and Assay of Precious Metals.—By Ernest A. Smith, Assoc. R. S. M. Deputy Assay Master, Sheffield Assay Office. Published by Charles Griffin & Company, London. 460 pages; 166 illustrations; size, 6 x 9 in.; cloth. Price, $4.50.

This book is an effort at a comprehensive treatment of the whole subject, and one cannot claim that the author has not succeeded in producing a work that will be well looked upon by the student and the adept in the practice of assaying. The various methods of sampling and of assaying ores, bullion and alloys of gold, silver, platinum, and the metals of the platinum group, are fully described. The author as deputy master of the Sheffield (Eng.) assay office, has a clear conception of the importance of accuracy in sampling and assaying operations. His book bristles throughout with the indication of the happy faculty of acquiring knowledge of the essentials and of imparting it in a practical way.

There are 25 chapters, the first five of which deal with the design and equipment of assay offices and the use of apparatus and appliances. Furnaces for the use of solid, gaseous and liquid fuel; balances and weights, and the art of weighing, etc., are included. The chapters on sampling are, in the writer's opinion, the most noteworthy of the book. A chapter on laboratory in a cyanide mill comprises a valuable 40 pages. The remaining chapters are devoted to assay work of the various metals.

It should be said that some of the sections are not so adequately dealt with as others, or as their importance would seem to warrant; but the value of the book lies more in the thoroughness which has accompanied the portion of what, in the author's mind, apparently stands out most prominently.

Another creditable feature of the work is its index. It is an admirable compilation, and adds materially to the degree to which the book will be found useful.

Reviewers frequently overlook the importance of advising prospective customers of the artisan construction of the book under discussion. The publishers have left no room for suggestions for improvements. The binding, paper, and printing are excellent, and the illustrations well proportioned. Taken altogether, the book should run into several editions.

PUBLICATIONS RECEIVED.

Ontario Agricultural and Experimental Union.—34th annual report (1912).

Victorian Institute of Engineers, Melbourne, Australia.—Vol. 12—1912 of the proceedings of the Institute. 254 pages; cloth binding; illustrated.

Canadian General Electric Company.—Presidential address of Mr. Frederic Nicholls, December 27th, 1913. Reprinted in the form of a 14-page booklet.

Library Catalogue.—Public Service Corporation of New Jersey. A 152-page catalogue of Authors and Titles of the Public Service Library of New Jersey.

Ontario Good Roads Association.—Proceedings of the 11th annual meeting, 1913, appended to the annual report of Mr. W. A. McLean, Provincial Engineer of Highways.

The Third International Road Congress.—A report by the Chief Engineer of the Board of Estimate and Apportionment of the City of New York upon the London Congress, June 23rd to 28th, 1913; 54 pages.

Municipal Lighting.—A report by special committee of the Municipal Lighting for South Hadley, Mass.; containing a report by Wm. Plattner, Consulting Engineer, 714 Old South Building, Boston, Mass.

Manufacture of Hollow Reinforced Concrete Poles, Piles and Pipe.—By R. M. Jones. A [illegible]-page illustrated description of the Jones process for the manufacture of hollow reinforced concrete poles, piles and pipe.

Department of Naval Service, Ottawa.—A report for year ending March 31st, 1913, including reports on the survey of tides and currents; hydrographic survey branch; radiotelegraph branch; Naval branch, etc. 128 pages, besides illustrations and maps.

The Meteorological Aspect of Smoke Problem.—By Mr. H. H. Kimball, Ph.D. Bulletin No. 5 of the Mellon Institute of Industrial Research in Pittsburg on Smoke Investigation. A 50-page pamphlet dealing with the general problem of the effect of smoke upon sunshine in large cities.

Wood-using Industries of New York.—The 28th bulletin of this character, which has been prepared by the Forest Service of the United States Department of Agriculture. A 215-page illustrated book, with numerous tables, showing the demand upon each Wood by each Industry.

Report on the Bureau of Supplies.—Department of Water, Gas and Electricity. City of New York. A 93-page report dealing with such phases of the Bureau, as scope, organization and administration, purchasing, inspecting, storage, records and issue, illustrated by photographs and colored charts.

Dangers to Workers from Dusts and Fumes and Methods of Protection.—Bulletin No. 127 of the United States Department of Labor, Bureau of Labor Statistics. Containing 62 plates exhibiting industrial machinery and appliances liable to endanger the health of the workers, and methods of remedy. This is No. 3 of a series on Industrial Accidents and Hygiene.

Problems of the Contractor.—By Leonard C. Wason, President of Aberthaw Construction Company, Boston, Mass. A 40-page booklet reprinted from the Journal of the Association of Engineering Societies for Nov. 19th, 1913; dealing with the relations between the contractor on one side, and the owner, engineer and the inspector, on the other, in the matter of building construction. Booklet sent free by the above company.

Report of the Transit Commissioner. City of Philadelphia. An exhaustive report in two volumes of the problem of improving the transit facilities of Philadelphia, containing definite recommendations, and plans for carrying them out, for a system of rapid, efficient and cheap transit throughout the city and suburbs. Vol. I. of 267 pages, contains sections devoted to a recommended rapid transit, its general design, estimates, traffic surveys, etc., and is well supplemented by tables, diagrams, etc. Vol. II. contains 69 maps and plans of systems in other cities, construction plan, time, time-distance, distance diagrams, etc. By Ford, Bacon and Davis, Consulting Engineers, and Mr. Merrit Taylor, Transit Commissioner.

PERSONAL.

W. J. MOORE, O.L.S., A.M.Can.Soc., C.E., has been appointed Town Engineer of Pembroke, Ontario.

G. P. COLE addressed a meeting of the Montreal Electrical Society last week on the subject of "Transformers."

C. H. MITCHELL, C.E., has been elected president of the Toronto Civic Guild, of which he has been vice-president for the past three years.

A. B. GARROW, B.A.Sc., assistant engineer, Main Drainage Department, city of Toronto, left last Friday for a few weeks holiday in Bermuda.

ERNEST A. RICHARDSON, City Commissioner of Saskatoon, has handed in his resignation, to take effect April

15th. Mr. Richardson will resume his former connection with the G. H. Archibald Construction Company of that city.

H. E. BALLANTYNE, B.A.Sc., a graduate of '93, School of Practical Science, and a prominent architect of New York City, addressed the University of Toronto Engineering Society recently on "The Architect and Engineer in Modern Architecture,"

J. B. CHALLIES, Superintendent, and J. T. Johnson, hydraulic engineer, were the representatives from the Water Power Branch Department of the Interior, at the recent session of the International Waterways Commission in Washington.

PAUL D. SARGENT, M.Am.Soc. C.E., Chief Engineer, State Highway Commission, Augusta, Me., on January 20th delivered an illustrated lecture on "Gravel and Its Use in Highway Construction" before the Graduate Students in Highway Engineering at Columbia University.

J. G. FETHERSTON is assistant designer in the engineering division of the Street Cleaning Department of the city of Toronto. Mr. Fetherston is a younger brother of Mr. John T. Fetherston, who was recently appointed Commissioner of Street Cleaning of New York City. Previous to coming to Toronto Mr. Fetherston had charge of the erection of an incinerator plant at Savannah, Ga.

J. E. JONES has accepted the position of mechanical engineer in the engineering division of the Street Cleaning and Refuse Department, city of Toronto. Mr. Jones was previously with the Electric Bond and Share Company of New York as chief designer. He has had considerable previous experience in hydro-electric and steam plant projects. Mr. Jones graduated from the School of Practical Science, Toronto, with the class of '94.

E. W. OLIVER, manager of construction, Canadian Northern Railway, Toronto, gave a talk, on Jan. 22nd, to the members of the Civil's Club of the University of Toronto, an organization among the civil engineering students of the third year in the Faculty of Applied Science and Engineering. Mr. Oliver dwelt upon the process of organization of railway companies, factors of location, supplies and construction procedure, and outlined the phases of railway work that presented opportunities for the civil engineer.

E. H. DRURY has returned to Canada from Chili, and has joined E. J. Walsh of Ottawa in the firm of Walsh and Drury, consulting engineers, Booth Building, Ottawa. Mr. Drury was general manager and chief engineer of the Longitudinal Railway of Chili, and had previously been connected with a number of other railways in Canada and Cuba, and also with the construction and operation of power houses in Canada and Mexico. Mr. Walsh has had a wide experience as engineer for various departments of the Dominion Government, in connection with a number of Canadian railroads, as chief engineer of Trent Canal surveys, in municipal engineering and in public works engineering in the West Indies for the Department of the Secretary of State for the Colonies.

OBITUARY.

The death is reported from British Columbia of Mr. JAS. D. SWORD, a prominent consulting mining engineer, and a resident of that province for over 20 years. Mr. Sword was widely known in Canada, Mexico and Colorado. He was actively associated with the Rossland and Kootenay activities in British Columbia in the earlier days. He was also associated with the founding of the Canadian Mining Institute. Death was due to accidental drowning while on a trip to record some assessment wórk on a mining claim.

ENGINEERING STAFF OF THE GREATER WINNIPEG WATER DISTRICT

The following engineers are those who are engaged on the Shoal Lake water supply project of the Greater Winnipeg Water District, of which W. G. CHACE, B.A.Sc., is chief engineer. (This scheme was discussed in *The Canadian Engineer*, Vol. 25, pp. 431 and 605, issues of September 11 and October 23, 1913.)

MAX V. SAUER is the Chief of Design in the Winnipeg office. He is a graduate of the University of Toronto, Faculty of Applied Science, 1902. Since taking his degree he served for two and one-half years in various capacities under Messrs. L. L. and P. N. Munn on the staff of the Ontario Power Company, Niagara Falls, Ont., having latterly been assistant to the mechanical engineer. For one year he was chief designer and had charge of transmission line structures on the staff of the Niagara Falls Power Company, being responsible there for the transmission line from the plant of the Canadian Niagara Power Company to Buffalo and for the Buffalo sub-station. The next year he spent as construction engineer for the Niagara, Lockport and Ontario Power Company in charge of their transmission lines between Niagara and Syracuse, N.Y. Since 1907, Mr. Sauer was first chief draughtsman, and then for four years, mechanical assistant and mechanical engineer for the Ontario Power Company. During this period, he served in a similar capacity on the design of the Salmon River Power Company's hydro-electric plant near Syracuse, N.Y.

GEORGE F. RICHAN.—A graduate of Acadia University, N.S., has been engaged nearly altogether in railway work, having begun with the New York and New England Railroad as rodman. He was engaged for 12 years in various capacities on the maintenance of way and on the construction staffs of the Boston and Albany Railroad, having amongst other duties that of locating engineer in charge of branch line work and on the re-location on the main line. His duties involved abolition of certain grade crossings and rearrangement of various railway services. He served throughout the entire period of preliminary and location surveys on the construction of the National Transcontinental Railway, having resigned after completing, in July, 1913, the duties of division engineer on Divisions Nos. 5 and 6.

ARCH PAGET.—Mr. Paget is also a railway man, having served from 1897 to 1908 in various capacities in the construction department of the western lines of the Canadian Pacific Railway. Since 1908 he has served in the employ of contractors as superintendent of construction and as engineer; and his last duty prior to joining the staff of the Greater Winnipeg Water District was the supervision of the double track work of the Canadian Pacific Railway on the Lake Superior division, district 3.

DOUGLAS L. McLEAN.—A graduate of McGill University in Civil Engineering, who won the British Association medal and prize in 1909. During his college course he served with railway engineers and with surveyors. Since graduation, he has been designer for Mr. J. B. McRae, consulting engineer of Ottawa, Ont., assistant chief engineer to the International Commission on the River St. John, and for two years has served the Water Power Branch of the Department of the Interior in explorations of the Winnipeg River, having latterly been chief engineer to the Manitoba Hydrographic Survey.

A. C. D. BLANCHARD.—A graduate of McGill University in Civil Engineering in 1901; was for five years assistant engineer and latterly construction engineer for the Canadian Niagara Power Company of Niagara Falls, Ont. He then served as engineer in charge of construction under Messrs. Ross and Holgate of Montreal in charge of the 32,000 horse-

power development of the West Kootenay Light, Heat and Power Company. He was then for four years assistant to the city engineer of Toronto, in charge of sewage disposal and intercepting sewers, gaining there both design and construction experience. From 1911 to 1913 Mr. Blanchard was city engineer of Lethbridge, Alta.

CHAS. J. BRUCE.—Received his engineering training in the field and in practice since 1903. He has served the Dominion Coal Company of Sydney, N.B., as chief mine surveyor for two years. He was for three years with the Dominion Government on the Trent Canal and for three years on the surveys and final location of the Hudson's Bay Railway.

Messrs. Richan, Paget, McLean, Blanchard and Bruce, are each in charge of a survey party in exploration and location of the aqueduct line.

The work to date has engaged the services of about 100 men, including engineers and their assistant labor. They have cross-sectioned and explored the country between Winnipeg and Indian Bay, all in Manitoba, and trial lines are being run for the aqueduct. Considerable success is being attained in effort to discover a uniform continuous down grade from Shoal Lake to Winnipeg, so that a gravity supply at minimum cost may be available in Winnipeg. The remainder of the winter will be required for completing studies of this problem.

A large staff has also been engaged in the office in the collating of field notes, in making the preliminary designs. Good progress can be reported in drafting of specifications for the preliminary stages of the work, as is evidenced by the fact that the Commission is already calling for tenders.

ANNUAL MEETING, TORONTO BRANCH, CANADIAN SOCIETY OF CIVIL ENGINEERS.

On Wednesday evening, January 21st, the annual meeting of the Toronto Branch of the Canadian Society of Civil Engineers was held in the lecture room of the Engineer's Club. Mr. E. A. James, chairman of the Branch, presided.

The treasurer's report, read by Mr. A. B. Garrow, secretary-treasurer of the Branch, showed a cash balance of $877.50, a large portion of which sum is to be expended forthwith in the enlargement of the already extensive library belonging to the Branch and open to its members in the library rooms of the Engineer's Club.

The election of officers for the coming year resulted in the unanimous selection of Mr. A. F. Stewart as chairman, and Mr. John S. Galbraith as secretary-treasurer. Messrs. J. G. G. Kerry, C. H. Mitchell and Prof. P. Gillespie were elected members of the executive committee. Mr. Kerry was also nominated as representative for District No. 5 of the nominating committee of the parent Society.

The proceedings of the evening included a discussion of the proposed extension to the library. It was generally felt that the members would derive much benefit from the compilation and publication of a comprehensive index, covering the libraries of the Toronto Branch of the Society, the Ontario Land Surveyors' Association, the Ontario Association of Architects and the Engineer's Club. A general lack of knowledge on the part of the members of the extent of the library and the books contained therein seemed to exist. Messrs. W. Chipman and T. C. Irving, Jun., made some valuable suggestions for the speedy carrying out of extensive library development. A library committee was appointed to investigate and recommend additions, this committee consisting of Prof. C. R. Young, and Messrs. A. L. Mudge and W. A. Hare.

Among those present were the following:—Members:—J. G. Kerry, A. F. Stewart, H. E. T. Haultain, J. G. Sing, Willis Chipman, A. R. Davis, C. H. Mitchell, C. R. Young, F. W. Thorold, G. A. McCarthy, J. R. W. Ambrose. Associate Members:—L. M. Arkley, F. B. Goldike, T. H. Hogg, E. T. Wilkie, J. Hutcheon, S. M. Oborn, J. M. M. Greig, Peter Gillespie, A. L. Mudge, W. A. Hare, T. R. Loudon, E. T. Brandon, W. A. Bucke, E. L. Cousins, E. R. Clarke, A W. Connor, E. A. James, A. B. Garrow, P. H. Mitchell, A. E. Jopp, P. W. Greene, T. C. Irving, Jr., O. L. Flanagan. Junior Members:—D. C. Blizard, C. C. Bothwell. Student Members:—R. P. Johnson, C. H. Fuller, D. H. Fleming, A. S. Miller, E. P. Muntz, John S. Galbraith.

CLAY WORKERS' ANNUAL MEETING.

The Canadian National Clay Products Association is in convention this week in Toronto. The following are among the speakers whose names appear on the programme of the meeting:—

Herbert N. Casson, Vice-President of H. K. McCann, New York; M. E. Gregory, President of the Brick Terra Cotta and Tile Company, Corning, N.Y., on "Commercial Side of the Clay Business"; Joseph Keele, Dominion Geological Survey; Prof. Edward Orton, Jun., Ohio State University, Columbus, Ohio, on "Ceramic Course"; Prof. Day, Ontario Agricultural College, Guelph; Prof. M. B. Baker of Queen's University, Kingston; A. F. Greaves-Walker, Ceramic Engineer with the Sun Brick Company, Toronto, on "Brickyard Kinks"; Miller Gibson, Ceramic Engineer, National Fireproofing Company, on "Different Types of Fireproofing, Their Manufacture and Burning"; John F. Wilde, Ceramic Engineer with E. H. Crandell Pressed Brick Company, Calgary, Alta., on "Types and Construction of Kiln Furnaces"; Dr. McKay, Principal of Toronto Technical School; D. O. McKinnon on "History of Our Association"; A. L. McCredie, on "Advertising Clay Products"; John Millar, Clayburn, B.C.

The Convention is being well attended and the gathering is quite representative of the ceramics industry of the Dominion.

COMING MEETINGS.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Annual meeting will be held in Montreal, Que., January 27-29, 1914. Secretary, Prof. C. H. McLeod, 176 Mansfield Street, Montreal, Que.

CANADIAN CLAY PRODUCTS MANUFACTURERS' ASSOCIATION.—Annual Convention to be held at King Edward Hotel, Toronto, Jan. 27th, 28th, 29th, 30th. Secretary, J. R. Walsh, 40 Blake Street, Toronto.

WESTERN ONTARIO CLAY PRODUCTS ASSOCIATION.—Convention to be held in Chatham, Ont., February 4 and 5, 1914.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

NATIONAL CONFERENCE ON CONCRETE ROAD BUILDING.—Meeting will be held in Chicago, Ill., February 12th to 14th, 1914. Secretary, J. P. Beck, 72 W. Adams Street, Chicago, Ill.

AMERICAN WATER WORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Deven, 47 State Street, Troy, N.Y.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21188—January 10—Authorizing V.V. & E. Ry. & Nav. Co. to construct spur for Campbell River Lumber Co., Ltd., near Crescent, B.C., to be constructed within six months from date of this Order.

21189—January 10—Authorizing C.N.R. & C.P.R. to operate trains over crossing in St. Boniface, Man., without first being brought to a stop.

21190—January 12—Authorizing C.N.R. to open for traffic revised line across Rainy Lake, Ont., from mileage 224.3 to 226.4, a distance of 2.1 miles.

21191—January 9—Approving location C.P.R. Swift Current Northwesterly Branch Line from a point in Sec. 20-28-6, W. 4 M., at mileage 169.0, thence in northwesterly direction to a point in Sec. 4-29-7, W. 4 M., mileage 175.0. Also authorizing the construction of said Branch across Seven (7) highways, mileages 169.10 to 174.61, Alberta.

21192—January 12—Authorizing C.P.R. to open for traffic third track from a point on north side of Queen St. subway, at Parkdale Station, to a point on south side of Royce Ave., at West Toronto, in City of Toronto, Ontario.

21193—January 10—Extending, until March 15th, 1914, time within which C.P.R. complete work of constructing additional track to present siding accommodation for use of Dodge Manufacturing Co., Ltd., at West Toronto.

21194—January 12—Authorizing G.T.R. to construct additional track across Inverness St., Village of Caledonia, Co. Haldimand, Ont.

21195—January 9—Authorizing G.T.P. Ry. to construct bridge across Endako River, at mileage 358 Prince Rupert East, B.C.

21196—January 10—Authorizing G.T.R. to reconstruct bridge No. 48 over Black Creek, at Mile Post 120.21 from Black Rock on 20th Dist., Tp. Downie, Co. Perth, Ontario.

21197—January 12—Authorizing Sandwich, Windsor and Amherstberg Ry. and Canada Southern Ry. to operate crossing of industrial spur of Canada Southern Ry. extending to plant of Postum Cereal Co., of Canada, Ltd., city of Windsor, Ont., on east side of Wellington Ave.; trains of Canada Southern Ry. and cars of Applicant Co. be brought to full stop before crossing diamond, and flagged over crossing by trainmen and conductors, respectively, in charge of said trains and cars.

21198—January 12—Authorizing G.T.P. Ry. to construct its main line across and divert 2 highways in B.C., mileage 461, Prince Rupert Easterly, Cariboo Dist., and mileage 357.3 Prince Rupert Easterly, in Stel-La-Qua Reserve, Rge. 5, Coast District.

21199—January 12—Authorizing C.P.R. to construct spur into premises of J. I. Case Threshing Machine Co., Regina, Sask.

21200—January 13—Authorizing C.P.R. to open for traffic portion of double track from mileage 67.7 to 76.8, Moose Jaw Sub. Div., Saskatchewan.

21201—January 13—Authorizing C.P.R. to operate over bridges at Guy, Aqueduct and Mountain Sts., Montreal, Que.

21202—January 13—Authorizing C.N.R. to construct across and divert public road in N.E. ¼ Sec. 14-28-9, W. 3 M., Sask., on its Delisle Branch.

[illegible]—January [illegible]—Authorizing C.P.R. to operate over bridge on Decarie Ave., city of Montreal, Que.

21204—January 13—Authorizing C.P.R. to construct its Weyburn-Stirling Branch Line across twenty (20) highways, Prov. Sask., mileage 299.145 to 316.765.

21205—January 14—Amending Order No. 21114, dated Dec. 30th, 1914, by striking out figures "165.95" wherever they occur in said Order, and inserting in lieu thereof figures "105.95."

21206—January 9—Approving revised location C.P.R. main linet, Lake Superior Div., Chapleau Sub. Div., as constructed from mileage 125.14 to 126.76 (mileage 127 old line), and from mileage 129.83 to 131.65 (mileage 132.27 old line), through Tps. No. 28, Gallagher, and Chapleau, Dist. Sudbury, Ont.

21207—January 9—Authorizing G.T.P. Ry. to construct bridge across Stoney Creek, mileage 397.1, Prince Rupert East, B.C.

21208—January 14—Authorizing, subject to terms of consent of village of Plessisville, G.T.R. to construct siding into premises of Plessisville Foundry Co., on Original Lot 171, Rge. 7, Tp. Somerset South, Co. Megantic, Que.

21209—January 14—Approving proposed Supplement No. 1 to C.N.R.'s Standard Freight Mileage Tariff for its Eastern Lines, C.R.C. No. E., 212: said Supplement, with copy of this Order, to be published in at least two consecutive weekly issues of "The Canada Gazette."

21210—January 15—Amending Order No. 18570, January 24th, 1913, by adding paragraph "2, that when road approaching crossing, mileage 38.90, is graded so that road along Tp. Line is passable, Co. put in crossing and diversion, if diversion is found necessary: detail plans be submitted for approval of Engineers of Board." Rescinding Order No. 19037, dated April 11th, 1913.

21211—January 15—Directing that C.P.R. remove station at Kruezburg, Man., from present location to a point on road allowance at east end of its yard.

21212—January 15—Approving revised location C.N.R., Con. 3, Tp. Halkirk, Dist. Rainy River, Ont., mileage 210.11 to 211.05.

21213—January 16—Authorizing Canada Southern Ry. and G.T.R. to use crossing of siding leading to Canadian Steel Foundries, Limited, Tp. Crowland, Co. Welland, Ont.; trains of both companies be brought to full stop before making crossing.

21214—January 12—Relieving C.P.R. from providing further protection at crossing of highway known as Cote du Sud, mileage 11, from Place Viger Station, Montreal, Ottawa, Sub. Div., Que.

21215—January 16—Authorizing C.P.R. to open for traffic portion of double track from Waldeck to Eaman, mileage 99.4 to 109.4, distance of 10 miles, Swift Current, Sub. Div., Sask.

21216—January 8—Amending Order No. 21026, Dec. 15th, 1913, by striking out paragraph 3 of said Order.

21217—January 16—Rescinding Order No. 19400, May 29th, 1913, in so far as it exempts C.N.Q.R. from fencing portion of right-of-way between mileages 23.5 to 34.

21218—January 16—Authorizing Can. Nor. Alta. Ry. to construct bridge across Stony River, Sec. 35-48-28, W. 5 M., Alta. Mileage 209.3.

21219—January 15—Authorizing G.T.R. to operate engines and cars over siding of Confederation Construction Co., Limited, on Lot 9, Con. 10, Tp. Grantham, Co. Lincoln, Ont., near Merritton.

21220—December 27—Directing G.T.R. to construct, at expense of W. J. Watson, Glencoe, Ont., farm crossing on Lot 9, Con. 2, Tp. Mosa, Ont., subject to certain conditions.

21221—January 16—Authorizing G.T.R. to construct extension of branch line, or siding, serving Empire Cotton Mills, Limited, at Welland, Ont., such extension being situate on Lot 24, Con. 5, Tp. Crowland, Co. Welland, Ont.

21222—January 16—Authorizing C.P.R. to construct, at grade, roadway in S.E. ¼ Sec. 19-12-29, W. 3 M., and roadway in N.W. ¼ Sec. 18-12-29, W. 3 M., at Cummings, Sask., across its main line tracks, Alta. Div., Medicine Hat Sub. Div.

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

RAILWAY CROSS TIES

SUITABLE WOODS — NATURE OF MECHANICAL WEAR — PROTECTION — THE VALUE OF TIE PLATES — TYPES USED BY VARIOUS ROADS

By J. L. BUSFIELD, B.Sc., A.C.G.I., A.M. Can. Soc. C.E.

IN the construction and maintenance of a railway the cross tie is in itself an almost insignificant item, but when one considers the fact that the railways in Canada have to face an expenditure of over 10 million dollars per annum on ties alone, they have a bearing on the economics of railway management of much greater importance than would at first appear possible. This expenditure is one that is increasing every year. The statistics are not yet available for the year 1913, but the amount actually spent on ties by the steam and electric railways of Canada was $5,540,769 in 1911, and $9,373,869 in 1912, an increase of 69%, so that there is no doubt but that the figure for 1913 will be well over the $10,000,000 mark.

The causes of this large increase are many, but the most prominent are: (1) The larger number used; (2) increase of cost per tie; (3) increased use of the more expensive hardwood ties, and (4) the shorter life of ties. Analyzing these items separately, the first needs little comment as the increase is a natural one due to the growth of railway mileage; a small proportion of this item is also accounted for by item (4), namely, the shorter life of ties.

The increased cost per tie is mostly caused by the greater demand and diminishing supply. Some years ago the supply was so unlimited that practically no ties were imported into Canada, and the railways could obtain very nearly all they might require from points in close proximity to their own lines, thus reducing the cost of haulage. But in recent years the available supply has become reduced and localized so that the railways have had to import ties to quite a considerable extent, large quantities of southern hard pine being brought over 1,500 miles from Louisiana and Georgia. In 1912 the value of imported ties was approximately $1,700,000, or 20% of the total expenditure of Canadian railways on ties. The average cost per tie of all the ties used in 1911 was 39c., and in 1912, 44c., and with the prices prevalent during 1913 there is little doubt but that there will be a similar increase in the average price for the year just passed.

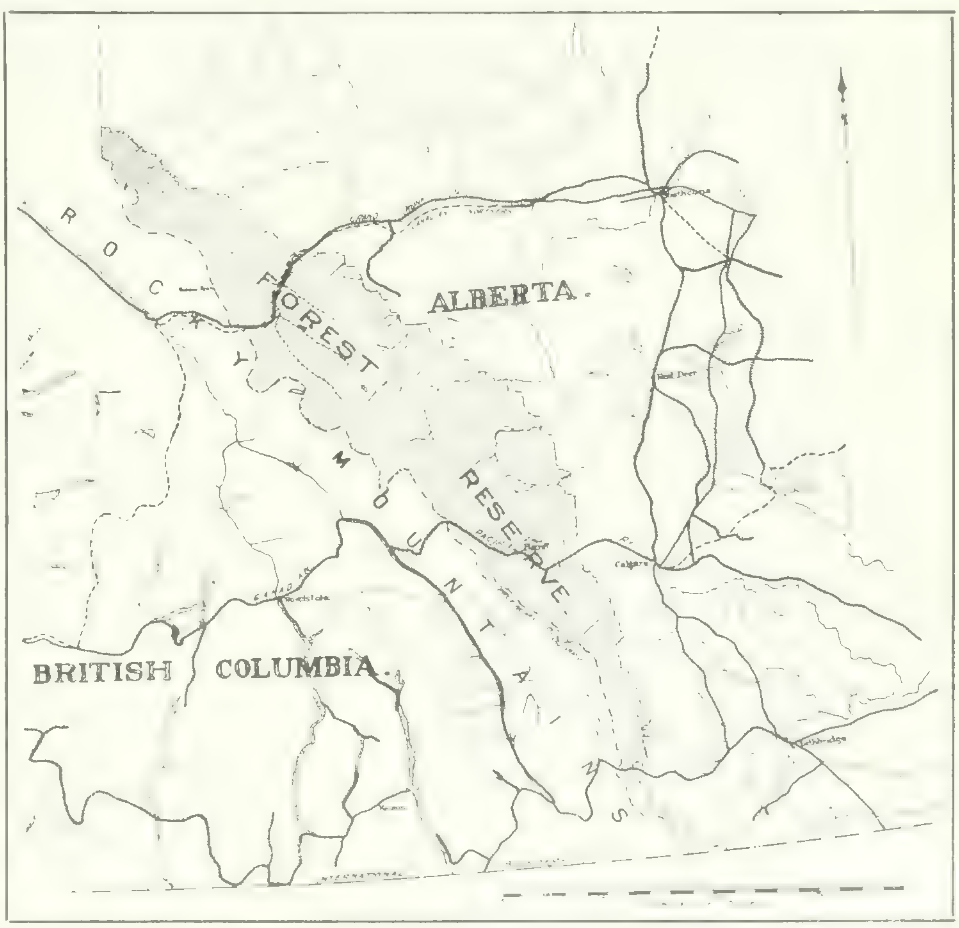

Fig. 1.—Rocky Mountain Forest Reserve.

There has been a steady increase in the use of hardwood ties to replace the softer kinds previously used. At one time there were more cedar ties used than any other kind, but in later years the number used has fluctuated considerably, while there has been a steady increase in the number of hardwood ties used, such as the oak and hard pine. In 1911 the percentages of these two kinds were 1.0 and .003 respectively of the total

number used of all kinds, while in 1912 these percentages increased to 4.4 and 3.1 respectively. There are about 19 different kinds of wood used for ties in this country and Table I. gives the approximate percentage of each kind used.

Table I.

Kind.	Properties.	Percentage.
Jack pine	Light, soft and durable	36.5
Cedar	Light, soft and durable	15.0
Douglas fir	Hard, strong and durable	10.2
Hemlock	Light, soft not strong or durable, brittle	9.1
Tamarack	Heavy, strong, hard and durable	8.5
Western larch	Heavy, strong, hard and durable	5.6
Oak	Tough, hard, strong	4.4
Eastern spruce	Light and soft	3.9
Hard Pine	Hard, tough, elastic and durable	3.1
Chestnut	Light, soft, not strong	1.2
Beech	Very hard, strong, tough, not durable	0.5
Western cedar	Light, soft and durable	0.4
Maple	Tough, heavy, hard and not durable	0.2
White pine	Soft, uniform and durable	0.2
Birch	Heavy, strong, hard	0.2
Red Pine	Heavy, strong, not durable	0.1
Balsam fir	Soft, light, not durable	0.1
Western spruce	Soft, light, not strong	0.1
Elm	Heavy, hard, very strong	0.1

Although the jack pine, cedar, and hemlock have prominent positions in this table their use is practically limited to tracks where the traffic is light, the railways in Eastern Canada having practically discarded these softer woods in favor of oak and hard pine, which are better able to withstand the heavy traffic common to these lines.

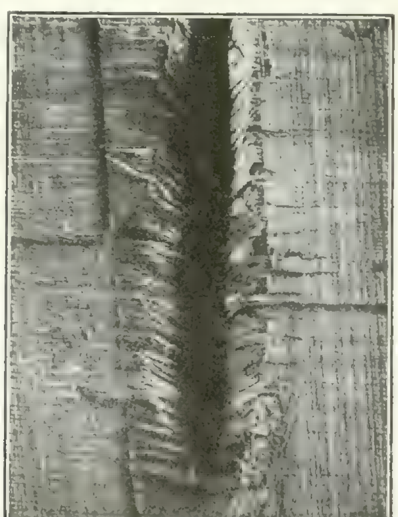

Fig. 2.—Effect of Driving Spike in Oak Tie.

The fourth item on the list of causes of the increased cost of ties to railways is the shorter life of ties. This at first may not be apparent, but it is nevertheless true; the actual time it takes for a tie to decay is no less to-day than it was in the past unless the decay is hastened by some extraneous cause—and that is what actually happens. As the traffic and tonnage over a track increases, so does the rail cutting and mechanical wear of the ties, and once the wood fibres are damaged in this way vegetable decay sets in much quicker, and the life of the tie is shortened by this decay, as well as by the mechanical disintegration.

As is naturally to be expected, both the railways and the governments are doing a great deal to counteract this tendency of increased expenditure on ties and timber, and briefly summarized, the following are the methods adopted for this end: Government legislation and conservation of forest lands; the maintenance of suitable tree plantations by railways; the reduction of mechanical wear by screw spikes, tie plates, etc.; the chemical treatment of ties to prolong their life; and the

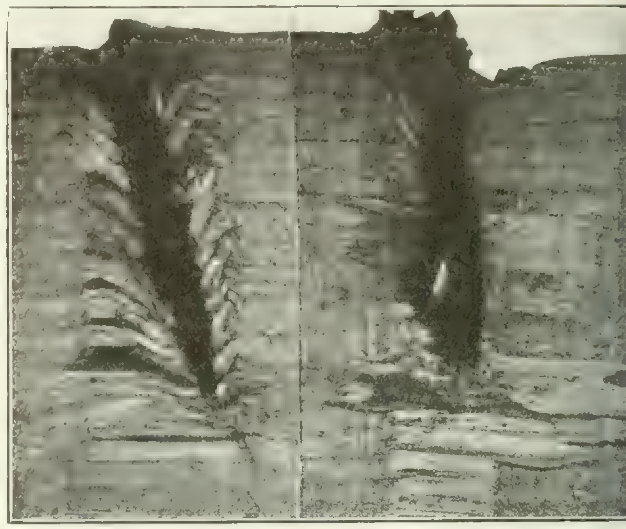

Fig. 3.—Effect of Spike on Tie After One and Three Years' Service.

use of ties of other materials than wood. It might be said that practically all these methods are still in the experimental stage, but it is of interest to note what has been done on these lines.

The Commission of Conservation of Canada has done considerable work in the past few years towards the conservation of the timber supply of the Dominion. In the year 1911 the attention of the Commission was largely paid to the prevention of forest fires, and from careful investigation it was found that about 34% of the forest fires to which causes could be assigned had been started by railway locomotives. As a direct result of this, an amendment was made to the Railway Act requiring railway companies to establish and maintain a service of fire rangers whenever so ordered by the Board of Railway Commissioners, and also requiring the railways to pay damages within certain limits for any fires caused by them. In addition to this legislation, a great deal was done in connection with forest reserves, and as a result the Rocky Mountain Forest Reserve Act was passed setting aside 17,900 sq. mi. in Alberta on the eastern slopes of the Rocky Mountains for a perpetual forest and game reserve. This national forest being the largest and most important in the Dominion, is worthy of a few words of description. As shown in Fig. 1, the eastern boundary is approximately defined by a line at elevation 4,000 ft., the western boundary is determined by the Interprovincial boundary, and the reserve rises to the west to peaks as high as 10,000 ft. The timber line is at an elevation of about 7,000 ft. The most useful trees found in this tract are the Engelmann spruce, the Douglas fir, and the Lodgepole pine. The Engelmann spruce is a tree with a light, soft wood, not very strong and found only in high altitudes. The Douglas fir is of the same species as some of the largest trees in the world, but does not reach such a size in the national

park as elsewhere. They average about 150 ft. high and 3 to 5 ft. in diam. The wood is usually very hard and strong and is useful for ties as well as for heavy construction work, piles, etc. The Lodgepole pine is a very rapid growing tree, has a strong wood and is used a great deal for all kinds of construction purposes.

A number of the larger railways of the United States have been carrying out experiments with plantations of their own on their outlying and other lands. In Table II. is given some of the work done and the cost of planting the trees.

Table II.

Railway and Location.	Kind of Trees.	First cost per 1,000.	Cost of planting per 1,000.

It will be noticed that the catalpa, locust and eucalyptus (or red gum) trees are the ones most favored for the railway plantations. These are trees which were until recently little known or used, but owing to many kinds of trees which were formerly quite plentiful, becoming more or less scarce, attention had to be given to those trees which would give the best results under artificial conditions. These trees all have the same property of very rapid growth. On the Atchison, Topeka and Santa Fe Railway ranch at San Deguito, Cal., 500 trees are planted every year of the blue gum and eucalyptus species. This tree is a native of Australia, but is successfully reared in California. It grows in low, swampy ground and also equally well in dry, arid mountain plains. It needs a warm climate as the young trees cannot withstand more than 2 or 3 degrees of frost. Freshly cut, the wood is pale in color, heavy, hard, durable, and very difficult to split. It is expected that by the time the trees are 20 yrs. old, they will yield 8 ties per tree, in addition to a quantity of by-products The catalpa tree is a native of the Mississippi Valley, but has been naturalized in many other localities east of the Rockies. The wood is coarse, brittle and not very strong, but is very durable in contact with soil. The trees grow from 40 to 60 ft. in height and 3 to 6 ft. in diam., with well formed trunks and large white, faintly mottled flowers. The yellow locust trees are widely cultivated in the States east of the Rockies. The wood is tough, durable, and unequalled for torsional strength. It has been classed in the first rank of American woods. The trees develop very rapidly but are subject to the depredations of insect borers. They grow from 50 to 70 ft. in height and 2 to 3 ft. in diam.

Protection of Ties From Mechanical Wear.—Many experiments have been made and remedies suggested for eliminating the damage done to a tie by such external agencies as the spike, rail-cutting, etc. When an ordinary cut spike is driven into a tie the wood fibres are broken, torn and generally disrupted. At the time the spike is first driven the damage is comparatively small, but as time passes decay sets in with greater rapidity and the tie becomes rotten around the spike. In Fig. 2 is illustrated the effect on an oak tie of driving into it an ordinary cut spike. In Fig. 3 is shown the resulting effects after one and 3 years' service. One method of obviating this damage to the wood structure of the tie is to bore a hole in the tie slightly smaller than the spike itself, so that when the spike is driven in the usual way there will be practically no damage to the wood fibres. The resisting power of a spike driven into a bored tie is very close to that of a spike driven in the ordinary way. (See Table III.). The comparatively small amount of damage that is done to the tie by a spike driven into a bored tie is shown in Fig. 4. Another method which has been largely experimented with is the substitution of a screw spike for the ordinary cut spike. The screw spike is being adopted as a standard by some of the railways in the States to be used in conjunction with tie plates. The screw spike can be used either as a direct fastening to the tie, or, as is almost invariably done in Europe, it can be screwed into a wooden plug or "dowel" first screwed into the tie. The question of the advantage or disadvantage of the dowel is one on which there is considerable difference of opinion, but the tests show that the screw has a greater holding power when used in conjunction with the dowel than when driven directly into the tie. Since the advent of chemically treated soft wood ties, the hardwood dowel has a distinct advantage of distributing the strain over a large area of the soft wood and also permitting the preservative chemical to reach the innermost pores of the wood at the point where it is most required. A standard screw spike used with and without a dowel is illustrated in Fig. 5. Table III. gives the holding power, as obtained by tests, of different kinds of spikes.

Table III.

	Mean. Lbs.	Maximum. Lbs.
Square spike in unbored tie	4,558	6,826
Round spike in unbored tie	2,478	6,066
Square spike in bored tie	4,082	5,810
Round spike in bored tie	4,108	6,940
Screw spike in bored tie	6,916	10,842
Screw spike in oak dowel	8,170	9,724

Tie Plates.—The use of tie plates is becoming more general on all the larger railways every year. A great many experiments have been made in order to determine the best type for use under varying conditions, but unlike track rails, the tie plate has not yet reached the stage of being standardized by any of the large engineering or railway institutions, and one well-known manufacturer of tie plates, who started with about 2 or 3 different styles, is now manufacturing 40 or 50 different kinds, some of them so similar that when placed side by side it is difficult to pick out the original plates from the more recent innovations. There is a great deal of difference of opinion on all the different points necessary to make an ideal tie plate. For instance, taking the under side, there are the questions of the proper number of flanges, their depth, position, and whether they should be longitudinal or transverse, or whether some form of claw is not preferable to a flange; or again, some advocate a tie plate with a perfectly smooth bottom. Taking the upper surface without considering the problem of the shoulders there are the questions, should it be smooth or corrugated, channelled or bossed? Even with regard to the spike holes there are points of difference in the standards of almost every railway.

The purpose of a tie plate is to distribute the load from the rail over a larger area of the tie than that covered by the base of the rail in order to reduce the abrasion of the tie by the cutting of the rail; to prevent decay of the tie from the same cause; and also to assist

in keeping the track to gauge and line on curves and places where there is a tendency of the rails to spread. By fulfilling these requirements the tie plate has the great advantage that it enables a comparatively soft tie to be used to advantage in places where the traffic is heavy, and in addition to this it will also prolong the life of a hardwood tie. A sub-committee of the American Railway Engineering Association devoted a great deal of time to the special study of this subject and took measurements of the actual abrasion of ties in service with and without tie plates. The opinion formed by this sub-committee was that flanged tie plates of suitable design, width and thickness, and properly applied on tangents as well as on curved track will lengthen the life of cross-ties to 2 or even 3 years, and in the meantime the track will have been maintained in better surface and line and at less cost than could have been done without the plates. The averages of the results obtained of measurements of the abrasion of ties by rail-cutting are given in Table IV.

Fig. 4.—Cut Spike in Bored Tie. **Fig. 5.—Screw Spike in Bored tie (left) and With Dowel (right).**

Table IV.—(White Oak Used for Ties Throughout) Abrasion of Ties by 85-lb. A.S.C.E. Rail, Without Tie Plates.

Alignment.	Traffic.	Age.	Outside edge of base of rail.	Inside edge of base of rail.	Remarks.
Tangent	Heavy	7 to 8 yrs.	[illegible] in.	[illegible] in.	Single track
"	"	8 yrs.	5/8 in.	3/8 in.	East Bd. track
Curve (slag ballast)	Light		[illegible] in.	[illegible] in.	Inner rail, yard track, outer rail tie plated, no abrasion
Tangent	Heavy	5 yrs.	3/4 in.	1/2 in.	East Bd. track
" (gravel ballast)	"	6 yrs.	1 1/16	[illegible] in.	
5 deg. curve	Heavy	—	3/4 in.	3/16 in.	Inner rail outer rail tie plated, no abrasion.
2 " "	Light	—	[illegible] in.	[illegible] in.	Fast Pass. trains
1 " "	"	—	[illegible] in.	[illegible] in.	" "
Tangent	"	—	[illegible] in.	[illegible] in.	" "
8 deg. curve	"	—	[illegible] in.	[illegible] in.	Tie plate on opposite ends of ties, no abrasion.

The requirements of a tie plate in general are as follows: The plate must be rigid enough to equally distribute the rail load over that part of the tie which it covers. If the plate is too thin it will buckle and the load will be transferred to the tie through a thin strip of metal the same width as the base of the rail, and the value of the plate for distributing the load will thus become nil. The tie plate must be rigidly held to the tie so as to prevent dirt and water collecting between it and the tie, and a great many railways favor the plate being so well embedded into the tie by means of flanges or claws so as to assist in the lateral displacement of the rail. In the case of flanges being used they should be deep enough to grip the wood but they should not be so deep as to damage the wood fibres, and when the flanges are placed longitudinally they help very considerably to make the plate rigid and the thickness can consequently be reduced.

In Table V. reports to the American Railway Engineering Association have been compiled to give a general idea of the different standards adopted in 1913 by the larger railways of the continent. A great deal of the variation is in the minor details and it must be borne in mind that what is suitable for one purpose would be absolutely unsuitable under different conditions. It is probable, however, that more universal standards will be adopted in the near future.

Table V.

Railway	Type of plate	No. of holes	Outside dimens. of plate
			Ins.
A. T. & S. F.	Pronged or corrug'd, transverse flange*	4	9x7½
Al. Cent. & Hud. Bay	Sellers patent	4	8½x6–80-lb.

Long Island	Longitudinal flange	4	9x6–100-lb. 8x6–80-lb.
Miss. Pac.	Flat, and corrugated	4	
Mich. Central	Transverse flange*	3	9x6–100-lb. 9x5–100-lb.
Northern Pac.	Longitudinal, for tans. and curves less than 3 deg.	3	8½x6–90-lb.
Northern Pac.	Pronged for curves over 3 deg.	2	8½x6–90-lb.
Norfolk & West'n	Longitudinal flange	4	9½x6–100-lb.
New York Cent.	One Longitudinal flange	4	9x6–100-lb. 8½x6–80-lb.
National of Mex.	Flat bottomed	4	
Pennsylvania, East	Transverse flange	6	13½x7–100-lb.
Pennsylvania, West	Pronged	4	9x7–100-lb.
Philadelphia & Read'g	Flat bottom	4	10x7.
Pittsburgh & Lake E.	Flat bottom*	4	8½x7.
Rock Island Lines	Flat with screw spikes, trans. flange, with cut spikes*	4	9½x6½–100-lb
T. & North Ont.	Sellers patent	4	8½x6

*Cut spike and screw. In all other cases cut spikes only.

From this table it will be seen that the great majority of railways are using a tie plate with some form of a flange, corrugation or claw which penetrate the wood of the tie, in preference to the smooth bottom plate. It has been claimed that a plate with a flange tends to break and check the tie, but the common experience seems to be rather to the contrary provided the plate is properly seated to the tie. There have been a great many cases put on record where ties with flanged plates have been removed from the track in a state of decay, but the has a shoulder in order to relieve the spikes of the lateral pressure of the rail. At the other end of the plate the top slopes down slightly in order to drain any water off its surface; to give the plate a grip on the ties it has corrugations running diagonally across its bottom surface. They are of moderate depth, as shown in Fig. 7, with the idea of enabling them to compress and grip the wood fibres without splitting open the tie, and admitting water and dirt. The plate takes sufficient hold on the

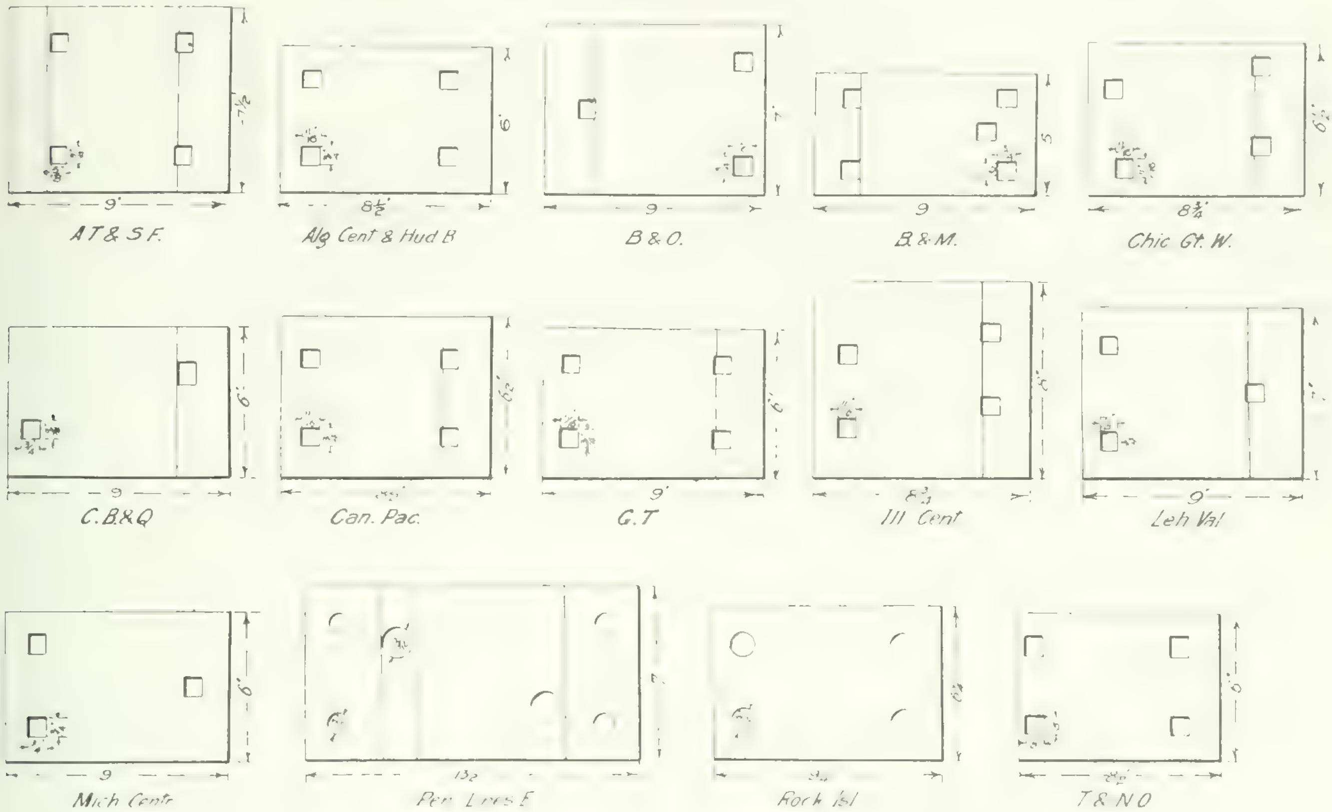

Fig. 6.—Different Forms of Standard Tie Plates.

portion under the plate has been no worse than the rest of the tie, and in many cases it has been found to be in ever better condition. Advocates of the transverse flange claim that the longitudinal flange does not give the necessary resistance to lateral displacement of the plate, whereas the transverse flange will give a big resistance to lateral displacement and at the same time the flanges do not need to be deep enough to damage the tie. On the other hand, it is claimed that the longitudinal flange wood surface to keep the track to gauge without pressure on the spikes.

In considering the relative merits of different tie plates the financial side of the question must not be overlooked. It stands to reason that the cost of the tie plate itself must not be so great as to negative any saving on the cost of the tie. It is difficult to put an actual value in dollars and cents on the services of the tie plate in keeping the track to line and gauge, but at the same

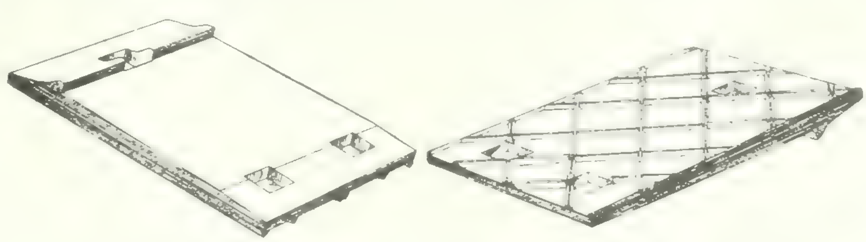

Fig. 7.—Top and Bottom Views of Sellers' Patent Tie Plate.

causes less damage to the ties, adds greatly to the buckling strength of the plate, and at the same time keeps the plate seated to the tie well enough to provide the necessary lateral resistance. It will be noticed that the Sellers patent tie plate is mentioned frequently in Table V. This plate is rolled from wrought iron, the top time the plate should increase the life of the tie to such an extent as to pay for its own cost, provided it is properly designed and applied.

[The question of the preservation of ties by chemical treatment and the use of ties of other materials than wood will be dealt with in subsequent articles.—Editor.]

CANADIAN SOCIETY OF CIVIL ENGINEERS

DETAILED REPORT OF THE PROCEEDINGS AT TWENTY-EIGHTH ANNUAL MEETING, HELD IN MONTREAL, JANUARY 27, 28 AND 29TH — RETIRING ADDRESS OF MR. PHELPS JOHNSON — REPORTS FROM THE VARIOUS BRANCHES, ETC.

The twenty-eighth annual meeting of the Canadian Society of Civil Engineers opened on Tuesday morning, January 27th, with an attendance that almost filled the auditorium of the Society's headquarters at 176 Mansfield Street, Montreal. Registration continued throughout the first two days and an exhausted supply of membership badges indicated that the attendance well exceeded that which had been anticipated.

The President, Mr. Phelps Johnson, was in the chair at Tuesday morning's session.

The meeting was called to order at 10.30 a.m. and the minutes of the last annual meeting were read and adopted. The President announced next order of business to be the appointment of scrutineers for votes for Officers and Members of Council. The following names had been suggested, viz., Messrs. J. Ewing, G. E. Fiset, R. McKillop, S. Blumenthal, V. A. G. Dey, B. Stewart, H. P. Borden, and B. O. Eriksen, and the pleasure of the meeting that they be delegated for the work was ascertained. In addition it was stated that scrutineers would be required for the amendments of by-laws. It had been suggested that Mr. E. C. Kerrigan take charge. He would need three or four assistants. The names of Mr. J. S. Hall and Mr. Robertson had been suggested. The President secured the concurrence of the meeting in the selection, together with power to add one or two to their numbers.

The President then reminded the members that they had been handed the report of the Council, and asked that it be received so that it might be open for discussion. It was moved by Mr. G. A. Mountain that the report be received. Mr. Leofred observed that there was a slightly larger attendance at the last annual meeting than this year, and wondered if a number of the western members were absent because they were dissatisfied with the place of this meeting. At the last meeting, he stated, a very large majority of them wanted the meeting to be held in the West, and it appeared to him that the ignoring of their wishes had caused the smaller attendance.

Mr. Rust stated that this matter was explained to the Western members, and it had been decided to go to the West next year, and that he had heard no expression of disapproval from any members from the West. They were perfectly satisfied that the Society should meet out there next year, and were not dissatisfied with the arrangements.

The President added that the action of the Council in not going to the West this year had met with the entire approval of the Victoria branch. At the time the post card vote had been proposed and sent out no one considered the fact that there would, perhaps, be two new transcontinental railway lines in operation to the coast next year, and it was not considered that the San Francisco Exposition would be in progress together with an Engineering Congress.

Report of Council.—The meeting then received the report of the Council. It was moved by Mr. Rust and seconded by Mr. Butler that the report be adopted.

Mr. Brayley asked if this report included the financial statement. Prof. McLeod replied that it was only as far as page 17 of the report that was then under consideration. Mr. Rust's motion carried and the report was adopted.

The President then announced that the report of the Library Committee was before the meeting and asked for any comment in connection with the report of the Library Committee or the House Committee.

Moved by Mr. Marceau and seconded by Mr. Brown that the report be adopted.

The President brought up the report of the Financial Committee to be found in the same pamphlet (pages 26 to 30). The statement of revenue and expenditure was on Pages 26 and 27; assets and liabilities on Pages 28 and 29, and on Page 30 was given the cost of the new building up to date.

Moved by Mr. Papineau and seconded by Mr. Lawrence that the report be received. It was then opened for discussion.

Mr. Brayley asked the meaning of the $5,000 on Page 26 of the assets and requested that it be explained.

Prof. McLeod explained that the Society had that much cash in the bank bearing interest. If it were put in the ordinary current account it would not be bearing interest.

Mr. Brayley asked if that account included the commuted fees. Prof. McLeod replied that it did not and that the commuted fees were very small.

Mr. Mitchell observed that in any case they would amount to several hundred dollars and enquired if that meant those who had become life members.

Mr. Brayley asked what was the total of the arrears fees. He noticed on Page 26 they were shown as $5,000. He desired to know what proportion that was of the total.

Prof. McLeod stated that a special statement would require to be made on that. It was carried forward from year to year. The auditor had thought that the Society had better keep that amount as representing the outstanding amount for arrears. He presumed an answer could be had for Mr. Brayley's question and given to him at the afternoon session.

Mr. Mitchell then asked how much of that represented arrears of over two years' standing.

Prof. McLeod agreed to include that in the afternoon return.

Mr. Brayley noticed an item of accounts outstanding, totaling $3,036, and asked if that was more than was general. Were they 30 or 60 day accounts, or did they run over a longer term?

Prof. McLeod replied that it was based largely on outstanding accounts entailed by printing.

Mr. Brayley stated that the Society had arrears fees and current fees, which would be used, presumably, for maintenance. Then it had advance fees and entrance fees which might be used more for buildings. Were any divisions made or was the Society being operated on entrance fees as well as current fees?

The President replied that he thought the total revenue had been just enough for the running of the Society.

Mr. Brayley made a suggestion that the Financial committee try to establish a more scientific basis of distribution for next year.

The President called attention to the fact that the surplus was only $646 and that the Society was running very close in the matter of finances.

It was moved by Mr. Mountain and seconded by Mr. Francis that the report of the Finance Committee be adopted.

Committee Reports.—The President then announced the next business as the reception and adoption of reports of Committees on Track, International Electrotechnical Commission, Reinforced Concrete, Sewage Disposal, Conservation and Testing Laboratories.

Prof. McLeod observed that it was customary for the chairmen of committees to present these reports, but that he had a telegram from Mr. Safford, Chairman of the Committee on Track, that he could not be present.

Mr. Francis, Chairman of the Committee on Concrete and Reinforced Concrete then presented the report of that committee re standard specifications for concrete and reinforced concrete, with the following letter of transmittal:

Mr. Francis.—In accordance with the instructions of the Council I beg to hand you herewith, for discussion by the membership of the Society, a preliminary draft of Standard Specifications for Concrete and Reinforced Concrete.

Owing to the immense amount of work involved in the preparation of a Standard Specification for Concrete and Reinforced Concrete, the Committee has been unable, in the time at their disposal since their appointment, to complete a document with which they feel entirely satisfied. In view of the fact, however, that the last Annual Meeting expressed a desire to have a standard specification, and that it is highly desirable that such a document should be available to the membership, the Committee recommends the adoption of the draft now submitted, after it will have been discussed by the membership.

At the same time the Committee respectfully requests that it be continued for another year in order that the work may be perfected, and that further knowledge may be obtained regarding shear action in beams. Should the request be granted, Mr. Morssen has kindly consented to make a number of test specimens upon which Professor Brown and Professor MacKay have been good enough to undertake to experiment, in order that this subject may be more fully understood.

In submitting this draft I should like to call attention to the personnel of the Committee, which is composed of engineers in various branches of construction. It contains representatives of McGill University, University of Toronto, Ecole Polytechnique and the University of Manitoba, as well as those engaged entirely in concrete and reinforced concrete construction, in steel construction, in bridge work and in private practice.

In the course of our work, upon which a great deal of time has been spent both in private and in committee meetings by many members, very liberal use has been made of all the latest authoritative documents on the subject, not only in the English tongue but in French and German. In addition the Committee has been most fortunate in having Mr. Morssen search also the Austrian and Swiss literature.

It is with the greatest of pleasure that I acknowledge the hearty co-operation of the members of the Committee, and particularly the indefatigable interest of Mr. Mattice, Mr. Monsarrat, Mr. Morssen, Professor Brown, Professor MacKay, Mr. Rolph, Mr. Gillespie and Dr. Galbraith.

[For a complete copy of this report members are referred to Pages 198-203 of January 22nd, 1914, issue of The Canadian Engineer.)

Mr. Francis then moved that the report be received, and that the Committee be continued until next annual meeting with instructions to make a final report.

Mr. Brown suggested an amendment, if acceptable to Mr. Francis, viz., that the committee confer with similar committees of other engineering societies, especially with the American Society of Civil Engineers and Institution of Civil Engineers, now making investigations along similar lines, with the idea of unifying the work, and making it universally wide in scope, thereby getting the best results

Mr. Francis replied that he would have very great pleasure in including Mr. Brown's suggestion with the motion if it were practicable, but that the committee had already made use of the reports of the other societies which were working for a long time along these lines. The Committee adopted their symbols, and had done everything possible to make the work conform with what other societies had been doing. The work of other Committees had been followed as closely as possible, not only in America, England, Ireland and Scotland, but in France, Germany, Austria, and Switzerland. It would be impracticable, Mr. Francis thought, to have a complete document ready inside of many years. These committees were composed of the most eminent engineers. They had a great deal of money at their disposal and this committee had not. Following the assumption of the last annual meeting it had merely presented the present draft for discussion. If this meeting allowed the work to go on, Mr. Morssen, as stated, had very kindly consented to make a series of special beams for the McGill Laboratories and the Professors of the University had stated their willingness to test them.

A discussion by Mr. Elmont followed:—

Mr. Elmont.—Mr. President, I would like to suggest that the specifications, which now deal comprehensively with both plain Concrete and Reinforced Concrete, should be arranged in such a way in the final draft, that the specifications for Concrete and those for Reinforced Concrete would be completely separated.

If they were bound in one pamphlet and the Reinforced Concrete specifications printed first, it would only be necessary to print in full a few sections for plain Concrete; while further information could be given by references to corresponding sections in the reinforced concrete specifications. As plain concrete and reinforced concrete structures are so widely different, I think that the specification would gain in clearness and practicability by this separation. A contractor who had to build a mass concrete structure according to this Society's specification for concrete structures, would, under the arrangement mentioned, find all the requirements his work had to meet under its own heading and concisely defined.

If it should be decided that it was desirable to separate the specifications, I would further suggest that the reinforced concrete specification be prefaced by a responsibility clause in accordance with the general practice followed by engineering societies.

As the specifications are arranged at present, Section 1, for instance, applies to all structures in which concrete is used. Undoubtedly, only Portland Cement should be used for reinforced concrete, but where economical conditions and the nature of the structure allow, it appears to me, that natural or slag cement should not be prohibited. This could be mentioned in the concrete specification, while the reinforced concrete specification would only permit Portland cement

In Section 3 it is stated that the fragments of the crushed stone shall pass a circular hole 2½" in diameter. The maximum size for reinforced concrete is given in Sections 56 and 57, while it seems correct, also, to place these figures under Section 3 of "Materials." I would suggest, that instead of giving the maximum size of 2½", which, it might be stated, might quite properly be exceeded in a number of structures, that the maximum size depends upon the nature of the structure. It would, perhaps, be well to mention some of the structures in which the size must not exceed ? or 2½"

As called for in Section 6, it is, no doubt, preferable that only fresh water should be applied to reinforced concrete, until further experiments have been made to determine the influence of the salt water, but for many mass concrete works, salt water is quite permissable.

With regard to the other paragraphs of the specification, I would like to submit that the headings "Method of Calculation" on Page 10, "Unit Stresses" on Page 12, and "General Requirement in Design" on Page 16, should be arranged as subheadings under a general heading called "Design."

The title of Section 19 might with advantage be changed to "Assumptions for Calculation" as they apply to all reinforced concrete design, and not only to beam and slab design. I would also suggest changing the beginning of the Section to read "Unless a more exact calculation is made, the calculation shall be based upon the following assumptions"; and placing Section 30, which is also a mere assumption, for the calculation, as "g"; also leaving out the 2nd, 3rd and 4th lines under "d", as these lines do not contain a new assumption, but simply a logical conclusion from the premises given in this Section.

The 2nd line of Section 20 I would suggest should be changed to, "A slab at the compression side of a beam may be............", and after the last word in the first paragraph, might perhaps be added, "When the main reinforcement of the slab is parallel to the beam, only half of the above given widths should be taken as an integral part of the beam. I would recommend that the three first lines of the 2nd paragraph of Section 20 be left out, as in many designs the slab is placed at the bottom side of the beam over the supports, and so would not agree with the paragraph as it stands. The same would be the case if there was no reinforcing in the compression side over the supports, which is not impossible.

In reference to Section 21, I would submit to the Committee, if, in the interest of the public safety, it would not be advisable to adopt some regulation for flat slabs, perhaps in line with those given in the building code for the City of Cleveland.

Section 23 does not state the size of the test piece from which the ultimate strengths are determined; this will no doubt be added in the final draft.

Section 31 gives the physical properties of the steel reinforcement, but does not mention the chemical requirements. They are, of course, generally agreed upon, but as they can be given in a few lines I would submit that they should be stated.

The first line of Section 33 states that "not more than three parts of sand shall be added to one part of cement"; this applies to plain concrete structures, the mortar in reinforced concrete work is determined by Sections 36 and 37. The requirement that the mortar shall not be less than 1:3 is a rather severe one, mixtures 1:4:8 or even 1:5:10 have been and are being used with satisfactory results in numerous cases, where the stresses in the concrete are insignificant, i.e., the main point is weight. For all structures of any importance advance tests should be made compulsory in order to determine the voids and the proper mixture of the aggregates.

In Section 45 it is stated, that "the foundations shall be at least as large as the dimensions on the approved drawings." I would suggest that these words should be left out. Someone might think that this does not apply to the other parts of the structure.

Section 43 deals with the reinforcement in columns. As all experiments bear out the importance of a proper spacing of the ties and the hooping, I would recommend that it be said that the ties should not be spaced farther apart than the diameter of the column, and in no case should they be spaced more than 12", and that the hooping in columns, where it is allowed for in the calculation, should not be spaced more than 1-8 of the diameter and never more than 2½".

The concrete in slabs shall, according to Section 60, be deposited continuously with the concrete in the beams. As far as I am aware, no experiments or practical results prove the urgent necessity of this method of procedure, while numerous experiments plainly indicate that the slab can be concreted when the stem of the beam has set, without any detriment to the united action of slab and beam or to the transmission of shear forces at the joint. If the Committee decides to change this section it should be pointed out, as a matter of precaution, that the web reinforcement should be anchored carefully both in the slab and at the bottom of the beam, and that the joint must not be too smooth and must be thoroughly cleansed before depositing the concrete for the slab.

Some very good measures to avoid failures in reinforced concrete work are established by the regulations given in Section 63, the greater part of the failures which have occured being undoubtedly due to too early removal of the forms. Only a few other societies' reinforced concrete specifications contain such detailed rules as we will secure. Some specifications make a distinction between slabs and beams over and under 10 or 15-foot span. This, I think, is worthy of imitation, now that we are using slabs without beams, resting only on columns of as much as 20 or even 25-foot span, and simply supported reinforced concrete beams have reached the 100-foot mark.

Mr. [illegible] suggesting that the allowable stress of reinforced concrete be reduced. Using concrete of 1-2-4 mix—with hard limestone, the strength had been given as 2,000 pounds. It had been suggested that 30 per cent. be taken, which would give a stress of 600 pounds to the extreme fibre. This made a concrete structure so heavy that it is almost prohibitive.

Mr. Lawrence stated that this was a big subject and that the committee had been working on it a comparatively short time. He suggested that the matter be taken up in Montreal as well as by each of the branches, and that the discussions be turned over to the committee to sift as they saw fit and to make any changes that they might think wise in the specifications. They could report to the membership at large during the year. He felt that it would be unwise to adopt the specification as it stood.

Mr. Mitchell stated, as a member of the Toronto branch, that members were very anxious to discuss the specification in Toronto, but that copies had arrived in Toronto a very short time ago, so that they had had no opportunity. He thought that if the branches could take up the matter as suggested it would be a very great benefit.

The President inquired if there was any further discussion on the subject, and if Mr. Francis' motion covered the point.

A motion was then made by Mr. Francis, seconded by Mr. Morssen: That the draft report as submitted be received; that the discussion thereon be submitted by the branches to the committee with instructions to report to the council, and that the committee be continued until next annual meeting with instructions to make a final report.

Mr. Lawrence inquired if the report would be sent to all the members or would it be left over until next year.

The President replied that it appeared to him to be a matter for the Council, and as soon as they deemed it wise, it be put into form and sent out as a pro tem specification to report progress.

Mr. Lawrence thought that it could be safely left to the incoming Council and that the report should be placed in the hands of the membership before next year. The motion was then carried.

Owing to the non-arrival of the chairmen of the committees on Sewage Disposal and Conservation, the reception of the reports, in order at this point, was postponed until later on.

Concerning the report of the Committee on Testing Laboratories, the President, as a member of that committee, stated that [illegible] found to do had been to [illegible] the Government [illegible] to represent the desirability of having testing laboratories.

Mr. Rust stated that he had met Mr. Keeter, the chairman, in New York, and he had said he would not be able to attend. Mr. Rust suggested that the committee be continued and that an occasional call be made upon the Government.

The President observed that there was a suggestion that the committee should be discontinued, and that the council take up the matter with the Government, whereupon Mr. Rust intimated that the matter could be left to the discretion of the council. It was then moved by Mr. Rust and seconded by Mr. [illegible] that the committee be discontinued and the matter left in the hands of the Council.

REPORT OF BOARD OF EXAMINERS.

The report for the Board of Examiners was given by Mr. MacKay. He remarked that four examinations had been held annually in former years with only a small number of candidates in attendance. During the past year examinations had been held only in May and November. The table in the report shows the number of candidates in each subject, also the number who passed and the number who failed. Two-thirds of the candidates of the whole passed. There had been only one or two candidates present on the primary subjects, i.e., for the membership of juniors. The standard so far adopted had been, he considered, rather easy and the examiners had given the candidates every opportunity and those who failed were certainly too weak to come under the definition as to those who were to be admitted to the Society to be qualified in design as well as practice engineering work.

A large number of men had been accepted on the presentation of certificates from their institutions. The majority of these certificates had come from Europe, largely from England and Scotland, although some had come from continental Europe. There had been great difficulty in such cases in maintaining the standard, because they had come from every sort of institution from a night school to institutions of very good standing indeed. In every case the committee had tried to give the benefit of the doubt to the candidates coming in. The board felt that these certificates should come before the educational committee since they were now in the position of saying who should be sent to examination and who should examine them. It would be more satisfactory to the board if some other party looked after the candidates, and the board could then entirely restrict its work to that of examining.

COMMITTEE APPOINTED RE GENERAL CLAUSES IN SPECIFICATIONS.

As other reports were not ready it was decided to postpone the reading of reports and hear any other matters which might be introduced. Mr. French, therefore, brought up the matter of having general clauses in regard to specifications.

Mr. French said that it would be well for the Society to appoint a committee to govern these specifications. In specifications there were certain things which were common to all. The members might readily call to mind clauses of a simple nature, and his experience had been that there was a wide variety to be met in such clauses. There was evidently a field of usefulness for a committee to consider the matter. He thought that the study of general clauses would be of great benefit to engineers.

Upon the suggestion of the President, Mr. French moved that the matter of appointing a committee to consider the matter of general clauses in specifications be left with the Council. The motion was seconded by Mr. Thomlinson.

The President remarked that formerly the matter of specifications and contracts had been taken up by each department and questioned whether it was practicable to make any specific rules.

Mr. Butler stated that in the province of Quebec the statutes protected the owner sufficiently, whether the engineer and contractor were covered by specifications or not. The province threw upon the engineer and the contractor or architect, as the case might be, the full responsibility for any defect that might develop within five or ten years the exact time having slipped his memory. He knew of a case which had gone to the Privy Council. It was held that the contractor had the onus upon him of knowing the defects of the foundation which were not exposed. This was the spire of St. James Cathedral. In every state of the United Stattes except Louisiana, and in every province in Canada except Quebec, the obligation was upon the contractor. He thought it would be of assistance if the Society could establish some sort of a standard in regard to specifications.

Mr. Francis expressed his belief that it would be very difficult to make a comprehensive specification to include all the trades with which an engineer had to deal. However he thought it would be an excellent thing for a committee to engage in the work of drafting special clauses.

A motion was put by Mr. French that the Council appoint a committee to consider the drafting of uniform general clauses in specifications and contracts which might be used by the profession in conjunction with specific clauses suited to the particular work on hand. He added that if the Society appointed a committee and made a report of their findings, that report would be of great assistance to the engineer in writing up his specifications. He had experienced trouble in writing up specifications,having left out clauses, or at other times put in a great deal more than was necessary.

Mr. Mitchell was inclined to believe that it was a very large order. He felt in favor of the matter being investigated, but was doubtful whether a committee could bring in an actual draft, particularly in a year's time. He understood the motion to say: "Consider the drafting of such a condition." He thought that if such a committee brought in a report on the advisability of the matter for next annual meeting, it would be all could be expected, and then at that meeting the recommendation of a general character which they had made could be discussed and then, if it was thought wise, the committee could be continued to carry on the details.

Mr. French agreed that this was a larger order, but it seemed to him that if a committee were appointed to consider the advisability of the matter and to report to the society at the next annual meeting little progress would have been made. The only thing to do would be to try; and it would be very much better for the committee to make an honest attempt to draw up such general clauses, unless the difficulties were such that they could not be surmounted. If the work progressed satisfactorily no member would begrudge the necessary time to make the trial complete.

The President asked Mr. French if it was his wish that this committee be appointed at the meeting or that it be left in the hands of the council; whereupon Mr. French expressed no preference in the matter. He merely desired to bring it to the attention of the Society. Mr. French's motion then carried.

Mr. Brown, managing engineer of the Mount Royal Tunnel, brought up the matter of giving the members an opportunity of seeing the tunnel on Thursday afternoon at 3 o'clock. Instructions were given for everyone to

prepare for a walk of two miles under Mount Royal, and not to expect to find the tunnel in any way dry.

Mr. White, Chairman of the Committee on Conservation, had arrived, and, at this stage read his report on Conservation. (See Page 204, The Canadian Engineer, for January 22nd, 1914). It was adopted, with the exception of the last six paragraphs., i.e., down to "Federal Government." Opposition to the passing of the report in toto was raised by Mr. Butler, who objected to the references to denatured alcohol, as not being along the lines of the Society. He objected to its undertaking to prescribe the policy for the Government with respect to alcohol. He expressed similar feelings in connection with the report's reference to sawdust utilisation.

Mr. White, very willingly, agreed that the portion objected to be dropped, whereupon his motion to adopt the report was seconded by Mr. Mitchell, and carried.

A motion was then put by Mr. Mitchell, which read as follows:

"That this Society commends the work of investigation being done by the Hydro-Electric Commission of the Province of Ontario, with respect to the control of the Grand River, and expresses the hope that the Commission will continue similar investigations throughout the province;

"That the Council communicate this resolution to the Commission."

Mr. Dion objected on the ground that the Hydro-Electric was not only a Commission, but was engaged with private interests. He thought it unwise for the Society to take any definite interest..

Mr. Mitchell contended that the purport of his motion was entirely in accord with the policy of the Society, and felt that it should commend such scientific investigation of great value to the public.

Mr. Coutlee remarked that it was rather difficult to make a recommendation other than a very general one, adding in a jocular manner that such commendation could not very well exclude the Ottawa River work, which brought loud applause from all members familiar with his connection with the same. Mr. Coutlee occasioned further smiles by his remarks concerning the Grand River and his suggestion that the vote of commendation be sent to those who live along its banks.

Col. Anderson did not think there was anything wrong in the procedure. It was not a question of the work. It seemed this Commission had done some scientific work as well as commercial work and that the motion was commending the scientific part of it.

The President called for a rising vote upon the motion, but it was lost.

The meeting then adjourned until the afternoon, the visiting members going to the Windsor Hotel, where they had a delightful luncheon as the guests of the Montreal members.

The meeting adjourned until 3.30 p.m.

TUESDAY AFTERNOON SESSION

The President announced that there were two additional reports on hand, one from the Cement Committee and one from the Sewage Disposal Committee. No member of the Cement Committee was present at the time to read the report, whereupon the President submitted two recommendations, one that the Council should select two general subjects out of the ten for first consideration and report. The second was in view of the volume of work done, and indicated that the membership should be increased from three to ten. The President then inquired if it was the pleasure of the meeting that the committee be continued, and that its recommendations be left in the hands of the incoming Council. Affirmed unanimously.

The President then called attention to the report of the Sewage Disposal Committee, observing that Mr. Chipman, a member of that committee, was present and intimating that the meeting would be pleased to hear from him. The report being brief, the secretary was asked to read it. Mr. Chipman then formally presented it to the Society.

The President inquired if it was the desire of the committee that the matter be left in abeyance, but Mr. Chipman, as a third member of the committe, felt hardly in a position to say. Mr. Johnson remarked, however, that it was rather important that the meeting take some action. Col. Anderson then moved that the report be adopted, and that the committee be retained.

Mr. Leofred rose to remark that this work was becoming more and more important, and thought the House of Commons was hardly prepared to meet the growing agitation. It would need a great deal of further study to see to what extent the towns were in a position to make a decision. He referred to the city of Verdun as bearing out his remarks. There was a liability of towns by reason of their inability to cope with the situation, and their inability to arrive at any decision on the matter, suffering severely through lack of proper knowledge and enormous expenditures. There was no question but that the matter required a great deal more study and investigation, and there was, in his opinion, no lack of work for this committee.

It was moved by Col. Anderson, and seconded by Mr. Mountain, that the committee be continued, with power to increase their membership. Carried.

It was then moved by Mr. C. H. Mitchell at the request of the president, and seconded by Mr. Francis, that the report of the committee for Cement be left until the next meeting.

COMMITTEE ON IMPROVED ENGINEERING SERVICE.

Col. Anderson, as a member of that Committee, and in the absence of its Chairman, stated that the idea of the Committee was to approach the Government with the intention of having the Engineering Service put on a more permanent basis, and that it be established with promotion and super-annuation. Most of the engineers in the employ of the Dominion Government were temporary employees. Reports had been made to the late Government with regard to this matter, and the Committee had been promised that the question should be taken up by the legislation. But since that time the Government had changed and it was necessary to begin the work over again. The present Government, especially the Minister of Public Works, had received the Committee very cordially, and had promised that the matter should be taken up in Parliament, but up to the present no action had been taken. It was very desirable, however, that the Engineering Service of the Government be put on a much better footing. (Applause.)

Mr. Leofred remarked that if anything was to be done it would be well for a delegation to go to Ottawa to try and accomplish the aim in Colonel Anderson's remarks. The motion that the Committee be continued was carried unanimously.

The P[illegible] report as that of the Educational Requirements Committee, and asked Mr. Marceau, the Chairman of that Committee, to submit his report.

Mr. Marceau stated that there was very little to report, and it was moved and seconded that the Committee be continued.

Mr. Johnson then took up the report on Steel Bridge Specifications and upon motion by Mr. Duggan, seconded by Mr. Butler, it was decided that this committee be also continued.

Upon taking up the remaining reports, that from the Committee on Rails, Mr. Mountain, as a member of the Committee, stated that it had done a lot of good work, but was not yet prepared to make a final report. They desired that it be continued, and wished to add the names of Mr. Butler and Mr. Stewart. These gentlemen, having consented to act, the motion was seconded by Mr. Rust and unanimously carried.

Mr. McLeod announced that at the request of Mr. White, the Chairman of the Committee of Conservation, the members of that committee meet Mr. White at the adjournment of the afternoon session.

While on the matter of committees, Mr. Mitchell proposed the formation of a Committee on Cast Iron Water Pipes and Specials. A report had been submitted by a committee some four years ago, but since that time it had not been worked upon either by the American Society of Civil Engineers or by our own Society. There had been found, however, matters in which improvement could still be made by other societies ,and they were making further studies. Mr. Mitchell, therefore, thought it was incumbent on the Society to do so as well. He proposed that a committee beformed to report at the annual meeting next year, and suggested the names of the following gentlemen:

Messrs. T. C. Irving, Jr., Chairman: Newton J. Ker, A. Currie, F. H. Pitcher, C. H. Mitchell, F. X. Leofred, C. L. Fellowes, and others.

Mr. Pitcher seconded this motion.

Mr. Irving moved that the committee appoint its own chairman, and Mr. Leofred, in seconding Mr. Irving, said he thoroughly agreed that the committee appoint its own chairman.

Mr. Mitchell, on a reminder from the Chairman that the minutes contained a ruling to this effect, said he would be quite willing to alter his motion to read in accordance with the bylaws.

Mr. Johnson then stated that the resolution as moved was that a committee be formed for Cast Iron Water Pipes and Specials composed of the afore-mentioned gentleman, and it was carried unanimously.

Col. Anderson then stated that if there was nothing before the meeting he would like to bring forward the resolution, following up what he had said with regard to the work done by Government engineers. He remarked that he had sent this notice of motion in to the Society over a month ago, expecting it would be sent out in printed form to the members. Continuing, Colonel Anderson said that he did not know if it was necessary to say much about the matter, as every engineer knew these facts, and the attention of the Government should be called to remedy the defects. The Dominion had good facilities at its disposal for obtaining the best results, but the fault appeared to be with the Government itself; there was absolutely no way in which a Government engineer could find out what plans were avail-

able in other Government departments, and this, in itself, was a very great defect. As Colonel Anderson had before stated the Committee had reported to the late Government, and it was now time for the present Government to have it turned up and more action taken with regard to it.

Mr. Butler remarked that the whole of the questions involved in the survey was in the hands of the Department of Militia and Defence and that they might be prevailed upon to take up the matter, and if possible put into effect the recommendations made by the Commission.

Mr. White, in replying to Colonel Anderson's references to the Government methods in matters pertaining to engineering generally, said it was simply a question of convenience. He was of the opinion that if the Canadian Government could be induced to establish an Engineering Corps, there would be no question then as to the establishment of the engineers in the employ of the Canadian Government.

The Chairman then announced the next order of business to be the reading of the reports of the branches.

REPORTS OF THE SOCIETY'S BRANCHES

CALGARY BRANCH FORMED

The first step toward the formation of the Calgary branch was taken in 1912, when Mr. J. T. Child invited a few of the members of the Society, living in Calgary, to meet in his office in the City Hall on July 2nd, to discuss the advisability of forming a branch in Calgary. While those who attended this meeting (six in number) were heartily in favor of forming a branch in Calgary, no definite steps were taken until March, 1913, when a circular letter, bearing the names of J. T. Child, H. B. Muckleston and F. H. Peters, was sent to all the members of the Canadian Society of Civil Engineers residing in the vicinity of Calgary, asking them to attend a meeting in the Government Irrigation Office in the old Post Office Building, on March 12th, 1913. This meeting was attended by nineteen corporate members and one student, all of whom were in favor of starting and signified their willingness to support a branch in Calgary. By-laws were adopted, temporary officers elected and subscriptions started at this meeting. Shortly after a formal application was forwarded to the Parent Society and the Calgary branch became a fact. Another meeting was held in the Government Irrigation Office on June 21st, 1913, and at this meeting the following officers were elected to act until the Annual Meeting in December:—Chairman, H. B. Muckleston; Secretary-Treasurer, P. M. Sauder; Executive Committee, H. B. Muckleston, F. H. Peters, A. S. Dawson, E. L. Miles and P. M. Sauder

Owing to the fact that a very large percentage of our members are engaged in work which takes them out of the City during the summer and fall, no regular programme was attempted during the summer, but a club room has recently been rented and it is expected that a regular programme of meetings, at about two weeks intervals, will be carried out during the winter and spring.

Messrs. T. E. Robinson and P. J. Jennings represented this branch at the Annual Convention of the Western Canada Irrigation Association, in Lethbridge, on August 4th, 5th and 6th, last, while Messrs. H. B. Muckleston, F. H. Peters and P. M. Sauder, of this branch, represented the Parent Society at this Convention.

H. A. Moore, General Manager of the Calgary Power Company, extended an invitation to the members of the branch to visit the new dam and power plant under construction at Kananaskis Falls, which a party of thirty-two accepted on November 29th. This trip was both pleasant and interesting.

The annual meeting was held on December 6th. The Secretary-Treasurer's report at that time showed the total receipts to date (subscriptions only) as $300.00, total disbursements $31.00 and balance in the bank $269.00. The chairman and secretary-treasurer were re-elected to serve another year and together with F. H. Peters, A. S. Dawson and G. Romanes, form the Executive Committee for 1914.

The year was closed by a dinner at 6 p.m., on Decmeber 30th, at which J. S. Dennis, Assistant to the President of the Canadian Pacific Railway Company and a member of the Council of the Canadian Society of Civil Engineers, was the guest of honour and gave a very interesting address on "Early Surveys and Surveyors of Western Canada." Respectfully submitted,

P. M. SAUDER, Secretary-Treasurer.

Calgary, January 10th, 1914.

FEW PAPERS AT KINGSTON

The following is all the report I have to make for Kingston:

The Annual Meeting of the Kingston branch was held on Jan. 23rd, and the following officers were elected for the current year: Chairman, Alexander Macphail; Sec.-Treasurer, L. W. Gill; Executive Committee, L. Malcolm, J. B. Cochrane and G. C. Wright.

On account of the small membership of this branch, there is not much incentive to the writing of papers for branch discussion. [illegible] only a limited number of meetings were held during the past year. Most of these meetings were called primarily for the discussion of proposed amendments to the by-laws of the Society.

Respectfully submitted,

L. W GILL, Sec.-Treasurer.

Kingston, Ont., Jan. 26th, 1914.

OTTAWA'S SPLENDID REPORT

On behalf of the Managing Committee of the Ottawa Branch we take pleasure in submitting the following report for the year 1913 namely:

Annual Meeting.—This was held as usual at the beginning of last October, and resulted in the election of the following officers for the season of 1913-14, namely: Chairman, G. A. Mountain; Managing Committee, M. F. Cochrane, F. J. Delaute, W. J. Dick Alex. Gray and W. S. Lawson; Secretary-Treasurer, A. B Lambe.

The standing Committees were afterwards struck as follows namely: Entertainment, W. J. Dick (Chairman), G. G. Gale and John Murphy.

Papers, Alex. Gray (Chairman), F. C. Askwith, W. S. Lawson and R. F. Uniacke.

Library, F. J. Delaute (Chairman), Valmore Denis, N. J. Slater, and J. C. Stewart.

Rooms, M. F. Cochrane (Chairman), W. F. McK. Bryce, K. M Cameron, and G. B. Dodhe.

The district Councillors are C. R. Coutlee, Ottawa, for 1911-12-13; D. McPherson, Ottawa, for 1912-13-14; S. J. Chapleau, Ottawa, for 1913-14-15.

The District Representative on the Nominating Committee is James White, Ottawa.

Membership.—Quite a number of changes have taken place during the year, as our members are constantly coming and going, but, except in the Student and Ottawa Associate classes, the net results are slight gains, as will be seen from the following table.

	January 1913	January 1914
Hon. Members	3	3
Members	49	51
Associate Members	112	116
Ottawa Associates	25	24
Juniors	12	15
Students	82	28
Totals	283	237

We much regret having to record the death during the year of three members, namely, Messrs. E. Jodoin, H. F. Cole and R. W Farley, and the permanent diasblement of an Ottawa Associate Mr. James Fyfe.

Papers and Meetings.—Our Papers Committee has been very fortunate in being able to present before the branch a number of most valuable addresses, many of which have been of interest to not only our own members but also to quite a large section of the general public. This has produced in several instances attendances far too large for our own rooms, in which cases we have been favored with the use of the Carnegie Library or the Normal School. The following is the list of papers given before the Branch in 1913, namely:

"Town Planning," Mr. N. Cauchon, Ottawa.

"Underground Conduit Construction," Mr. A. A. Dion, Ottawa.

"A Holiday Trip to the Panama Canal," Mr. J. Murphy, Ottawa.

"Waterways versus Railway Transportation," Mr. James White, Ottawa.

"Railroad Signalling," Mr. R. F. Morkill, Montreal.

"Street Railway Track Construction," Mr. R. M. Hannaford, Montreal

"The Coquitlam Dam," Mr. G. R. G. Conway, Vancouver

"Economic and Social Effects of Transportation," Dr. Adam Shortt, Ottawa.

"Automatic Cab Signalling," Mr. H. A. Dupre, Ottawa.

"Economics of the Panama Canal," Mr. James White, Ottawa.

Many of the above addresses were illustrated by lantern slides, and, as has already been stated, all were well attended, the average number lately present being close to one hundred, several of the audiences containing a fair proportion of ladies. The Meetings are held on the first and third Thursdays of each month throughout the winter season, namely from October to March inclusive.

Our Managing Committee meets regularly at 1 p.m. on the first Monday of each month, with special meetings as are from time to time found necessary.

Entertainment.—The Entertainment Committee this season organized for the Branch a most delightful Dinner, held on December 4th at the Chateau Laurier, one hundred and fifteen being present. As a further means of promoting mutual acquaintance among our members a system of monthly lunches has also been inaugurated.

Library.—This is gradually working into fairly good shape, the Branch having been the recipient of quite a number of books, to the donors of which we are much indebted, and the Reading Room being equipped with all the more prominent engineering magazines.

Rooms.—These remain as heretofore, because, while it is fully recognized that they are not entirely suitable for our purpose, our funds have not permitted us to contract for larger premises. It is hoped, however, that we will not only be able to get larger and better quarters in the near future, but also to equip them with a lantern, blackboard, etc.

In the meantime we are under many obligations to the authorities of the Normal School and Carnegie Library for having so kindly loaned us their meeting rooms when ours were inadequate to hold our audiences, to the Conservation Commission for the frequent use of their lantern, and to the Ottawa Electric Company for special services from which to operate it.

Finances.—The furnishing of our rooms has, up to the present, made serious inroads into our income. but we are now substantially clear of that account, and so expect that in the near future we will be able to provide somewhat more liberally for some other pressing necessities of the Branch.

American Society of Civil Engineers.—As you are aware, the above Society honoured Ottawa by making this City the meeting place for their 1913 Summer Convention. Through the energy of a Committee, of which Mr. C. H. Keefer was Chairman and Mr. S. J. Chapleau, Secretary, the local members of the American Society and the Ottawa Branch of the Canadian Society, assisted by very kind and generous support, financial and otherwise, from the Dominion Government, and by many private contributions, were able to provide what was universally conceded to be most excellent entertainment for the four hundred odd members and guests of the American Society who came to the Convention.

All of which is respectfully submitted:

GEO. A. MOUNTAIN, Chairman; A. B. LAMBE, Sec.-Treasurer.

Ottawa, January 10th, 1914.

QUEBEC REPORTS PROGRESS

The Council of the Quebec Branch of the Canadian Society of Civil Engineers presents the following report on the work of said branch during the year 1913:

Roll of the branch:—At present, the membership stands as follows: Members, 20; Associate Members, 38; Associates (branch), 2; Juniors, 12; Students, 23; Total, 95.

Annual Meeting:—The Annual Meeting of the Quebec branch was held on January 20th, 1913, under the Presidency of Mr. L. A. Vallee. The following officers were elected for the year 1913:—President, A. R. Decary; Secretary, A. Amos; Councillors, J. F. Guay, S. S. Oliver and H. Ortiz.

The past-presidents are A. E. Doucet, P. E. Parent and W. D. Baillarge.

Meetings:—The Quebec branch held 10 Business Meetings during the year 1913. Papers, etc., submitted by the Council of the Society and by the different branches were discussed. The proposed amendments to the By-law No. 8 were unanimously disapproved by the Quebec branch. This branch is of the opinion that the Annual Meetings of the Canadian Society of Civil Engineers should be held at its Headquarters. One conference on Good Roads and Road Construction was made by Mr. Gabriel Henry, Chief Engineer of the Provincial Department of Highways. This conference was most interesting and greatly appreciated; the president in proposing a vote of thanks to Mr. Henry, expressed the desire that the example given by this gentleman should be followed by all the members of the Quebec branch.

A. R. DECARY, President; A. AMOS, Secretary.

Quebec, January 17th, 1914.

TORONTO HELD ANNUAL MEETING ONLY

The executive of the Toronto Branch begs to present herewith the Annual Report for the year 1913. The services of a very active and able worker in the interests of the Society were lost when Mr. Parker Kemble left last February to take up his residence in Cincinnati, Ohio. He was on the Executive of the Branch and it was due to his efforts that our Library is in its present satisfactory condition.

A card index has been prepared, under the direction of the Library Committee of the Engineers' Club, of the combined libraries of the Toronto Branch, The Association of Ontario Land Surveyors, and the Ontario Association of Architects. These books are all located at the Engineer's Club and will by this means be accessible to all members of the three societies. Reference is also made on the cards to technical books on the shelves of the Toronto Reference Library and of the University of Toronto Library, so that excellent opportunity is afforded for consulting the authorities on almost every subject.

The membership of the Toronto Branch this year is as follows: Members, 42; Associate Members, 102; Associates, 8; Juniors, 28; Students, 35; Total, 315.

These figures represent the names on the roll in October 1913, and show an increase over the figures for 1912 of 16 corporate members, 1 associate and 6 juniors, and a decrease of 8 students.

This last figure is very much to be deplored in Toronto, where 100 new men are registering in Science each year, and the present Executive begs to suggest to the officers for the following year that some special means be adopted for reaching the younger men, and interesting them in the work of the Society. The formation of an Association of Students, as is done in connection with the Institution of Civil Engineers, would, no doubt, serve this purpose. Papers could be read by the students and trips of inspection made that would prove to be of great interest and benefit.

The lack of interest in the meetings by the members has been responsible for the fact that no papers were read before the Branch this year, and it is hoped that papers of sufficient interest to attract a good attendance at the meetings in the coming year will be secured. The officers for the year 1914-15 are: Chairman, A. F. Stewart: Hon. Sec.-Treas., J. S. Galbraith: Executive Committee, J. G. G. Kerry, C. H. Mitchell, Prof. P. Gillespie and E. A. James (ex officio).

Respectfully submitted,

E. A. JAMES, Chairman; A. B. GARROW, Hon. Sec.-Treas.

Toronto, January 20th, 1914.

VANCOUVER DID GOOD WORK

The present membership of the Branch is 146, distributed as follows: Members, 42; Associate Members, 74; Associates, 1; Juniors, 11; Students, 18.

During the year the Branch has held twelve meetings besides the meetings of the Convention of the British Columbia Members, held here on the 12th and 13th December. The following papers were read:

"The Pulp and Paper Industry in B. C.," by C. H. Vogel.

"The Burrard Inlet Joint Sewerage Scheme," by A. D. Creer,

"The Outlook for Mining in B.C.," by C. E. Cartwright.

"Some Public Works and Explorations in B.C.," since 1880. by F. C. Gamble.

"Modern Methods in the Manufacture of Portland Cement," by H. K. G. Bamber.

"Coquitlam-Buntzen Hydro-Electric Development." by G. R. G. Conway.

"Stave Falls Hydro-Electric Development," by R. F. Hayward

At the meeting of January 20th, the following officers were elected: Chairman, G. R. G. Conway; Vice-Chairman, L. G. Robinson; Secretary-Treasurer, F. P. Wilson; Executive, C. E. Cartwright and W. A. Clement; Auditors, A. D. Creer and H. P. Archibald

At the meeting of April 21st new by-laws were adopted. The by-laws increased the Executive Committee from five to seven, the date for the election of officers was changed to May, the retiring officers to hold office until the opening meeting in October. Messrs. C. G. DuCane and A. D. Creer were elected to fill the vacancies on the executive, and it was decided that the present officers should hold office until October, 1914.

The second annual dinner was held at the University Club on March 29th. About one hundred and ten members and guests were present. During the summer months, the following excursions were arranged by the branch, and many of the members attended: May 10th, to Coquitlam Dam, through the courtesy of the Vancouver Power Co.; June 6th, Special train over Saanich Railway, provided by the couetrsy of the B. C. Electric Railway, to Bentwood Bay, where the Steam Turbine Plant was examined, and to Bamberton where the members were shown over the new

plant of the Associated Cement Co., through the courtesy of Mr. Bamber, Managing Director of the Company; July 12th, to the Stave Falls Power Plant, through the courtesy of the Western Canada Power Company; Sept. 27th, to the Lake Buntzen Power Plant, by the courtesy of the Vancouver Power Company.

Yours faithfully, J. R. GRANT, Acting Secy.-Treas.

Vancouver, December 31st, 1913.

VICTORIA MEMBERSHIP GROWING

During the past year our Branch held 10 meetings with an average attendance of 18 and the following papers were read, viz.,

February 13th. "Some Engineering Works in B.C." (first section). Illustrated with lantern slides. F. C. Gamble, Vice-President.

November 13th. "Some disregarded stresses at joints and ends of steel in reinforced concrete construction." H. A. Icke.

December 11th. "A cellular method of vibrated reinforced concrete construction." J. B. Holdcroft.

Our membership increased from 62 to 82 but owing to the removal of 2 corporate members from our district, the net total stands at 80, distributed as follows: Members, 16; Associate Members, 29; Juniors, 8; Students, 4; Assoc. of Branch, 23; Total, 80.

All our Branch Associates are engineers who have applied for admission to Can. Soc. C. E. At the annual meeting held on December 11th the following officers were elected for 1914:

Chairman, F. C. Gamble (re-elected); Vice-Chairman, D. O. Lewis; Treasurer, A. E. Foreman (re-elected); Secretary, R. W. Macintyre (re-elected); Executive, the above officers with L. W. Toms and E. H. Harrison; Auditors, H. A. Icke and F. A. Richardson

With a view to developing the social side of the profession, receptions are being held in the Club rooms during the winter months, and attended by members and ladies. The year's programme closed with 2nd annual convention of B.C. members in Vancouver on December 13th. It is our intention to keep a register of all engineers belonging to the Branch who are available for employment, giving record and qualifications in each case. From this a list will be compiled and forwarded to the Provincial Government and municipal bodies in B.C.

Respectfully submitted,

R. W. MACINTYRE, Secretary.

Victoria, January 1st, 1914.

E.E. AND M.E. SECTIONS AT WINNIPEG

The Manitoba Branch of the Canadian Society of Civil Engineers begs to submit the following annual report for the year 1913. The officers for the year 1913 were as follows:

Chairman, J. G. Legrand; Executive Committee, W. A. Duff, D. A. Ross, W. L. MacKenzie and Frank Lee; Secretary-Treasurer, E. Brydone-Jack.

Meetings.—The following papers were read and discussed at the regular meetings of the Branch:

"Some Facts Concerning the Panama Canal," by J. G. Sullivan.

"The Use of Asphaltum in Protecting Levees and Railway Embankments," by Mr. Percy.

"The Auxiliary Steam Plant of the Winnipeg Electric Railway," by D. A. Ross.

"Steam Power Plant for Mechanical Department Yards at Divisional Points," by H. Lorimer.

The attendance at these meetings averaged about thirty. There is a total membership of the Branch of two hundred and eighty-three, classified as follows: Members, 33; Associate members, 101; Associates, 1; Juniors, 9; Students, 89; Local Associates, 50;

At the first of the year an electrical section of the Branch was formed which held meetings independently of the regular meetings of the Branch. At these meetings the following papers were presented.

"Physical Characteristics and Source of Illumination," by E. P. Fetherstonhaugh.

"Engineering Aspects of Illumination," by J. G. Glassco.

"Economics and Aesthetics of Illumination," by H. N. Ruttan.

"Recent Developments and Electrical Operation of Coal Docks" by F. H. Farmer.

"The Diesel Crude Oil Engine," by C. F. Bowring.

"Electric Heating from the Economic Stand Point," by Wm. Aldridge.

"Underground Cables," by M. B. Stewart.

"Comparison of British and Canadian Practice in the Distribution of Electrical Energy," by E. V. Caton.

There was a demonstration of resuscitation from electrical shock given by Mr. Aldridge at one of the meetings.

A mechanical section of the Branch was also formed at the end of the year, but no meetings were held prior to December 1st, 1913.

The Branch has co-operated with the Western Canada Railway Club and secured a room in the Industrial Bureau Building, where the members can have access to engineering periodicals, and where the nucleus of a library is being established.

At the annual meeting held on December 4th, the following officers were elected for 1914: Chairman, E. Brydone-Jack; Executive Committee, Frank Lee, W. L. MacKenzie and D. A. Ross; Secretary Treasurer; G. E. Bell.

The annual dinner was held on December 16th, 1913, in the Fort Garry Hotel, at which about ninety members and guests attended. The treasurer's report showed a balance in hand at the end of the year of $645.89.

Yours truly,

G. E. BELL, Secretary-Treasurer.

Winnipeg, January 7th, 1914.

The report of the Quebec Branch was the first on the list. The Secretary presented the report, which was received and adopted.

Mr. Leofred, in seconding the motion that the report be adopted, said he regretted there were no officers of the Quebec branch to read the report.

The report of the Ottawa branch was then submitted to the meeting by Mr. Dick. It was proposed and seconded that this report be received and adopted.

The Secretary then read the report of the Kingston branch. A remark was made as to whether a branch of this kind is doing enough work to warrant their receiving back a part of their funds.

Mr. Coutlee strongly opposed such criticism of these smaller branches or suggestions that they should be cut off, but that wherever there was a number of men in a branch of the Society, it was always best to give its members the benefit of that branch's work and the facilities at the Society's disposal. He did not think that any branch should be cut off under any pretext whatever.

The next report was from the Toronto branch and was read by Mr. J. S. Galbraith, the newly elected secretary-treasurer, in the absence of the chairman and the secretary for 1913.

Moved by Mr. T. C. Irving, Jr., and seconded by Mr. C. H. Mitchell, that the report be received and adopted. Carried.

It was then remarked, by way of criticism, that, according to the report the Toronto branch had hardly done sufficient work during the year to warrant giving them $575 out of the funds. According to the report all they had done was to elect officers and compile a card index. Mr. T. C. Irving, as an officer of the Toronto branch last year, ex-officio, stated that the branch was not in the position of the Ottawa and other branches. The Toronto branch did not have to have house committees, or an annual dinner, for the reason that the Engineers' Club had an annual dinner. Regarding the library, of which so little is said in the report, he regretted very much that the chairman had not seen fit to elaborate on the books added to the library. He thought they had in the Toronto branch the latest and most modern books on engineering.

Mr. Leofred remarked that the branches would undoubtedly show better results a little later on. Patience should be displayed.

Mr. Irving, then stated that it was proposed next year to build a new Engineers' Club in Toronto, and that money would likely be needed to be spent by the Toronto branch on the library and in arranging to make the headquarters of the branch in the new Engineers' Club. He remarked that the branch, in his estimation, should be congratulated instead of being criticized upon its large surplus.

Mr. Chipman rose to defend the Toronto branch. It had not, perhaps, given as good an account of itself as the Society had a right to expect, during the last few years, but there had been disadvantages in Toronto. With respect to finances it was his opinion that each branch had a right to spend its money in any way it deemed best fit in accordance with the by-laws of the Society. Toronto was husbanding its resources with a view to co-operating in the future with the Engineers' Club.

Prof. Haultain remarked that the Toronto members regretted the neglect which was apparent, but that they were "turning over a new leaf." There had been 44 members at the last annual meeting—more than at any previous annual meeting in years, and more, in fact, than the total attendance at the past several annual meetings. Interest was being warmly renewed and they were thankful to have $575.00 to begin with.

Mr. Harkom thought that there was one point which had not been fully considered, and that was the encouragement of the branches all over the Dominion. He strongly recommended that the Society should do all in its power to encourage its branches.

The Secretary then read the report of the Manitoba branch, which was duly accepted.

After the reading of the reports from the Calgary and the Vancouver branches, it was duly proposed and seconded that they be received and adopted. Carried.

The Secretary, after reading the report from the Victoria branch, said that in the matter of the last two reports he had in hand a somewhat voluminous report of that convention for the benefit of this meeting, and desired to know if those present would like it read.

Mr. Rust said he thought there was hardly any necessity, as it would take too much time. He knew they were very successful and very interesting, he having been present at the convention.

After much discussion an original motion respecting the report of this convention as well as the several amendments, were withdrawn, and it was eventually accepted, on the motion of Mr. Johnson, that the report be read Wednesday afternoon at 3 o'clock.

The presidential address was then delivered, the Secretary assisting because Mr. Johnson had a severe cold.

The address was received with much applause and appreciation, which was suitably acknowledged by the President.

PRESIDENTIAL ADDRESS

Remarks of Retiring President Had to be Brief Unfortunately Owing to Bronchial Attack

Gentlemen,—It is decreed by custom that a retiring President of the Society shall make an address. A good number of my predecessors in the office, following what was probably to them the line of least resistance, have given you a paper on some engineering topic.

I considered following this course, but abandoned the idea for the reason that it seemed impracticable to treat in a satisfactory way a problem in bridge construction without the aid of diagrams and lantern illustrations.

A general review of the progress made in the different fields of engineering, or a review of the more important works that have been carried out in Canada, are both beyond my limitations. I shall, therefore, speak to you only on Society matters, and I am the more ready to do this for the reason that at our last annual meeting and later in published correspondence, complaint was loudly voiced that the Society was not doing enough for its members, and the Officers and Council of the Society did not escape serious criticism.

The objects and purposes of the Society are in its Charter stated to be, "to facilitate the acquirement and interchange of professional knowledge among its members."

It seems evident that this basic purpose of the Society can best be achieved by having enrolled in its membership a large proportion of the able and active engineers of the country, by the interchange of thought and of experience at its meetings and particularly by the reading, discussion and circulation of papers on important and interesting works or investigations.

The Society was organized 26 years ago by a few of the then prominent engineers of Eastern Canada. The movement met with the enthusiastic support of most of the Engineers then in active practice, and at the time of the first annual meeting in 1888 there were 225 members and 65 associate members, or a total corporate membership of 290. From that date the number has steadily increased until we have at present the time 622 members and 1,313 associate members, or a corporate membership of 1,935. A few of these members, less than 40 in all, have come in under the Quebec Act, and a few more in this Province have joined almost under compulsion because of the Act, but the large majority have joined without pressure and without special solicitation, evidently because they considered membership in the Society beneficial and that to belong to it gave them a standing in the profession and in the community that otherwise they would not have.

While the growth of the Society in numbers has been very satisfactory, there has been no corresponding growth in the enthusiasm of its members, as evidenced by attendance at the meetings, by the preparation and contribution of papers, or of discussion on the papers submitted, but rather the reverse. The first eight years of the Society's history there was an average corporate membership of 378 and an average of 13 papers per year were submitted, read and published. The last 18 years the average corporate membership has been 921 and the average number of papers per year, again 13. In the first 8 years a paper was presented by one member out of 29. During the last 18 years we have had one paper for each 71 members. During the last 3 years we have had one paper for each 132 members.

Real enthusiasm cannot perhaps be worked up to order, but we can all do our duty, and I would call your attention that following our election we have all agreed "to promote the objects of the Society so far as in our power", and "to present to the Society an original communication" (meaning a paper) "or some scientific work for the library."

I fear a great many members have so far overlooked this pledge and hope for a great increase in the number of papers in the near future. I would particularly urge that the younger members prepare and submit papers describing the work on which they are engaged, or of which they have good knowledge, and this as much for their own sake as for the good of the Society, for the presentation of a paper of merit will go a long way toward giving them a professional standing they cannot well gain in other ways. A good paper need not necessarily be based on a large and important work, or even a successful one, for failures are often the source of very valuable information.

In connection with the complaint that the Society has not been doing enough for its members, it will be interesting to inquire what other Societies of similar nature are doing for their members. The Societies which at once come to mind for comparison are the Institution of Civil Engineers of Great Britain and the American Society of Civil Engineers. Both of these Societies have been long established and have a large membership, both have accumulated valuable properties and have annual surplusses of revenue over ordinary expenditures greater than our entire gross revenue. With ample means at their command and with able management it would seem that we may reasonably expect to find these Societies rendering their members every obvious useful service.

The British Institution of Civil Engineers publishes and distributes to its members four volumes per year, each volume containing the reports of the meetings that have been held since the last issue and a list of those admitted as students or as members, or transferred from one class to another. The papers read at the meetings and the oral and written discussions thereon are published, as well as a number of "selected papers" which apparently have not been read and discussed but are considered worthy of publication. A good part of each volume is devoted to "Abstracts of Papers in Scientific Transactions and Periodicals," a typical volume devoting over 100 pages to short reviews of 170 selected articles. The abstracts in the volume examined bear the initials of thirteen different reviewers, and this suggests that the work is not done by the Secretary's staff, but by writers familiar with engineering subjects, specially engaged for the work.

The American Society of Civil Engineers publishes in pamphlet form ten volumes of proceedings per year, each containing brief reports of the meetings of the Society and of the Board of Direction, which corresponds to the Council of the Society, the names of members elected and transferred from one class to another, a list of additions to the library with a synopsis of the contents of the more important books and gives a list of recent engineering articles of interest, reviewing for this purpose more than 100 publications. Each volume also contains a number of original papers with the discussions thereon.

It will be seen that both of these Societies not only publish their transactions more frequently than our Society, but go to considerable expense in keeping their members advised as to recent engineering literature.

Aside from their activity in this direction I am unable to find that these older and larger Societies do their members any service which we are not endeavoring to do for our members, and it is to be borne in mind that these Societies are financially able to do for their members every useful service considered desirable.

Neither of these Societies has branches or divisions corresponding to our own, though there are a number of local "Associations of Members of the A.S.C.E." in various parts of the United States which hold regular meetings and read and discuss papers as do our Branches. These associations have Charters approved by the Parent Society but receive no financial assistance from it.

Apparently the only useful suggestions we can get from the practice of these two older Societies are the desirability of more frequent reports to the membership, and keeping the members advised of current engineering literature, the latter a matter of considerable expense which the finances of the Society have not heretofore permitted.

The criticisms made at our meetings and in correspondence have as a rule been very general and with few specific suggestions. There seems to be a feeling that the officers and the Council are not doing all they should, that they are not keeping the members well posted, that the Council is not fairly representative of the different districts, and that it would be well if its members were younger and more enthusiastic and if they served shorter terms.

The remedy for these faults, if they exist, is in the hands of the membership at large, for it can make and alter By-laws, can designate the Nominating Committee, and can elect Councillors, and through them control the policy of the Society.

Some of the members, I believe a very small proportion evidently feel strongly that the Society should interest itself in the troubles of its individual members, with the Municipalities and Corporations employing them, and particularly that the Society should take active steps to keep out so-called Alien Engineers, and conserve Canadian business for the members of the Society.

I can conceive of no course so sure to discredit and disrupt the Society as to adopt Labor Union methods,and interfere in the disputes of engineers with their employers.

I agree that Canadian work should as a rule be done by members of this Society, but pressure to this end can best be exerted by the local members and branches, and I feel strongly that except in connection with works handled direct by the Dominion Government, the Society should not officially intervene.

On the whole I consider the complaints that have been made to have little support in existing conditions and believe that the Society has in the past done for its members about all that could reasonably

be expected. I do think, however, that the members of the Society have in great measure failed to do for the Society and for themselves all they should and believe they can hereafter, by taking a more active interest in it, by contributing and discussing papers, by attending meetings of the Society and Branches, by paying more attention to the applications for membership and advising the Council in regard thereto, and in other ways, make the Society of use to themselves and at the same time promote its interests.

In conclusion I wish to point out one way in which it may be the Society can be of great use to members without engagements or desirous of changing their employment.

The suggestion comes through the Engineering News of the 21st of August last, which, in an article headed "Making Membership in an Engineering Society a Tangible Asset," states that the "Junior Institution of Engineers" in England, a Society of which I have no special knowledge, has undertaken the establishment of a permanent Engineers' Register which will give a complete record of the professional career of every member, the purpose being to form a sort of clearing house to assist members in improving their positions by systematically recording the particulars of their experience and technical training, and by effecting the introductions to engineering employers of members who possess such qualifications as may fit them for vacant positions. To establish and maintain a Register of this nature would involve considerable expense, and would require the hearty co-operation of all members. I think, however, the suggestions well worthy the serious consideration of the incoming Council.

(NOTE:—The attention of members of the Society is respectfully called to the fact that "The Information Department" of The Canadian Engineer has, for five years past, kept the very kind of records advocated by Mr. Johnson. The complete record of any engineer who cares to supply the necessary data concerning himself, is kept on file. This file is open for inspection to any employer whose desire to add to or change his staff is bona-fide. Great care must be exercised not to allow the personal data in this file to be shown indiscriminately. Through this Information Department upwards of three hundred engineers have secured or changed positions.

Should the incoming Council adopt Mr. Johnson's suggestion, and appoint a manager to conduct such a file as a department of the Society, The Canadian Engineer hereby offers to present to the Society the entire records of its Information Department, upon the assumption that the work, if undertaken by the Society, would be prosecuted with greater thoroughness than is possible for any technical paper.—EDITOR.)

WEDNESDAY AFTERNOON SESSION

The meeting opened at 3 o'clock with a good attendance. Mr. Johnson was in the chair.

The report of the Convention of the British Columbia branches was read in part by Prof. McLeod, bringing out the fact that the members of that province were not inclined to concur in spirit with the action of the Council in the matter of sending out information concerning the vote on by-laws.

The President explained this particular point to have arisen from the feeling on the part of the Council that some communication on its behalf should accompany the by-law which was being mailed to the members, relating to the establishment of a provincial division of the Society in British Columbia.

At the September meeting at which the by-law, proposed by the Council, had been brought up, there had been no difference of opinion concerning it excepting the question of financial aid from the funds of the Society. The form of the by-law was not objected to insofar as it incorporated the proposed association with the existing branches. The underlying idea was that the association thus formed should not supercede the branches but that the Society should communicate more directly with the branches than with the association.

The by-law which the British Columbia branches submitted later differed from that proposed by the Council, the British Columbia members apparently being under the impression that the Council's by-law rather ignored their wishes.

Mr. Johnson thought that, when the Council was considering the submitted by-law, it might possibly have been adopted had it not been for the fact that the Council's by-law had been passed by a large meeting. It was felt that the decision of this larger meeting should not have been upset by the smaller meeting.

As far as the Council was concerned, therefore, it had no alternative, said Mr. Johnson, but had sent out both by-laws. As they covered the same ground, it was deemed essential to call the attention of the members to the fact that they were by-laws dealing with the same subject. A clause inserted in the communication for this purpose had—in the opinion of the British Columbia members—influenced voters in favor of the Council's by-law and against their own. Hence their objection.

This situation was the subject of discussion during the greater part of the afternoon. At the outset several members inquired why the whole communication had not been read by the Secretary on Tuesday. Mr. Kennedy replied that it was largely the proceedings of the convention of the Vancouver and Victoria branches, containing papers upon such subjects as "The Training of Young Engineers," and "The Question of a Common Level Datum," and other matters quite removed from the subject under discussion. They were not read, because it was desired to confine the discussion to the main subject.

The action of the Council, in inserting the explanatory paragraph in the communication which had been sent out, was upheld. The paragraph itself was endorsed in sentiment by the members. The discussion reverted to conditions peculiar to the western provinces, and the importance of recognizing that the western members had a better conception of these conditions than eastern members, generally speaking, could possibly have. It digressed to the matter of qualification of candidates for membership, whereupon the President observed that the Council would be greatly assisted in the passing of applications by receiving whatever information members might be able to furnish regarding candidates. Several members emphasized the fact that the Council had to rely largely upon such assistance; naturally having no personal acquaintance with many of the applicants.

Returning to the chief subject under discussion, it was maintained that the Society should do all it could to further the interest of all its branches, and that those most distant from headquarters should particularly be given all possible co-operation. The efforts to restrict the membership to well qualified men were heartily commended, and it was recognized that the advice of members residing in the same province as the applicant is most valuable in this regard.

The widely scattering discussion experienced a concentrating effect from a resolution submitted by Mr. Kerry, which was afterwards amended by Mr. Harkom's motion, seconded by Mr. Dietrich, and adopted. (Upon further consideration, however, it was felt that the wording of this amended resolution conveyed an impression different than anything intended, and it was rescinded at Thursday morning's meeting. A new resolution with better phraseology was substituted.)

A communication from the Manitoba branch was the next subject for consideration, but discussion was postponed by motion.

Complying with a request made at the Tuesday morning session for further particulars of arrears fees outstanding at the end of 1913, the secretary presented the following information:

"For 1913 the unpaid subscriptions amounted, for members $1469; for associate members, $4,456; for associates, $85; for juniors, $530; for students, $384. Total, $6,944"

"Arrears for 1912 and previous years, members, $964; associate members, $3,907; associates, $125; juniors, $403; students $395. Total $5,794.

"Sum total of outstanding arrears is $12,709. It was estimated by the auditor that these were worth $5,000 as indicated in the financial report submitted Tuesday.

"The statement which should have accompanied the report as to the number of members was as follows:

"Quebec, 40 corporate members, 9 non-corporate members.
"Ottawa, 156 corporate, 45 non-corporate.
"Kingston, 14 corporate, 6 non-corporate.
"Toronto, 128 corporate, 81 non-corporate.
"Manitoba, 130 corporate, 80 non-corporate.
"Calgary 30 corporate, 5 non-corporate.
"Vancouver, 114 corporate.
"Victoria, 40 corporate, 8 non-corporate.
"Total, 638 corporate, 248 non-corporate."

Mr. Jamieson remarked that the statement showed a state of affairs that should not exist. It was a large amount of arrears. This same question had been brought up from year to year, and instead of improving it was getting worse. It seemed that members were carried on the list long after the age limit had expired.

The President suggested that if he referred to the report of the Council it would be found that 437 students were dropped from the list during the past year because of over age or non-payment of dues. Mr. Brayley suggested that the matter be taken up by the finance committee to see if there was room for improvement.

Upon motion by Col. Anderson, the meeting was adjourned.

EXCURSION TO BRIDGE WORKS

The excursion to the St. Lawrence Bridge Company's shops at Rockfield was attended by about 250 of the members, special cars for the trip having been placed at the disposal of the visitors by the Montreal Tramways Company.

Upon arrival a thorough inspection of the plant disclosed many very interesting features in its construction and in the facilities to be seen there for the fabrication of the superstructure of the Quebec bridge.

After completing the tour through the shops a luncheon was served by the Company in the Templet Shop, at which a number of addresses were given.

THURSDAY MORNING SESSION.

The President called the meeting to order at 10.20 a.m.

It was decided to re-consider the resolution submitted by Mr. Harkom at the Wednesday afternoon session, and after thorough reconsideration it was rescinded.

Mr. Kerry submitted the following resolution to take its place:—

"That this meeting has considered the resolution of the British Columbia Branches, objecting to the action of the Council in commenting on a proposed amendment to the By-laws, and is of the opinion,

"(1) That the Society welcomes any expression of opinion or advice from the Council concerning matters of general import with which the Society proposes to deal.

"(2) That it suggests that such opinion or advice be printed independently of the ballot to which it refers.

"(3) That the incoming Council be entrusted to further deal with the development of the branch and divisional system as part of the organization of the Society."

Mr. Ross, in seconding the motion, observed that it contained the substance of the previous resolution and in much better shape. Carried.

The Secretary read the report of the Gzowski Medal Committee, which was received and adopted. He then read the report of the Examiners on students' papers. The meeting agreed to award two prizes in the General Section.

The Secretary next submitted the report re the amendment of By-laws.

The amendments proposed with regard to By-laws Nos. 9, 20, 36 and 51 of the Society were adopted. The amendments proposed with regard to By-law No. 8 of the Society were rejected. The new By-law No. 56, proposed by the Council and by certain members resident in British Columbia, did not have the necessary two-thirds majority vote to carry. The existing By-law No. 56 to be renumbered 57 was adopted.

The Secretary read the report of the Scrutineers and election of officers and members of the Council.

The officers elected to serve on the Council are as follows:

President:—M. J. Butler, C.M.G., Montreal.

Vice-President:—R. A. Ross, Montreal.

Councillors:—Representing District No. 1.—Montreal and district within 25 miles:—J. M. R. Fairbairn and H. M. MacKay, Montreal.

Representing District No. 2.—Newfoundland, Nova Scotia, Prince Edward Island, New Brunswick and the United States:—R. McColl, Halifax.

Representing District No. 3.—Province of Quebec (outside of the Headquarters district), countries outside of Canada, Newfoundland and the U.S.A.:—A. R. Decary, Quebec.

Representing District No. 4.—Ottawa and the Province of Ontario east of and including Lindsay:—R. F. Uniacke, Ottawa.

Representing District No. 5.—The Province of Ontario west of Lindsay:—W. A. Bucke, Toronto.

Representing District No. 6.—The Provinces of Alberta, Saskatchewan and Manitoba:—F. Lee, Winnipeg.

Representing District No. 7.—The Province of British Columbia:—G. R. G. Conway, Vancouver.

The report was received and adopted.

At this juncture the retiring President, Mr. Phelps Johnson, rose and surrendered the Chair to the new President, Mr. M. J. Butler. There was loud applause on Mr. Butler's taking the chair. He remarked that he could only faintly express his appreciation of the very great honor conferred on him by asking him to succeed Mr. Johnson, and to accept the highest position in the Society.

The President then announced the next in order of business to be the election of members for the nominating committee. The Secretary read the results of the ballots.

The President inquired whether there was any further business to bring before the Society.

Mr. R. B. Rogers announced that he desired to bring before the Society a matter referred to in the late president's address, reading as follows:—"While the growth of the Society in numbers has been very satisfactory, there has been no corresponding growth in the enthusiasm of its members, as evidenced by attendance at the meetings, by the preparation and contribution of papers, or of discussion on the papers submitted, but rather the reverse."

Mr. Rogers thought that cognizance should be taken of this reference. It was a matter of vital importance, and should be thoroughly looked into. He moved that a committee be formed to consider means to increase the enthusiasm of the members in general throughout the Society, the committee to report in six months to the Council; and that their report be printed and sent to the members, the matter to be brought up at the next annual meeting.

This motion was seconded by Mr. Kennedy.

Mr. Francis, speaking at length against the motion, said he was not aware of such lack of enthusiasm. On the contrary he thought that the members were as enthusiastic as they ever were, and that he was rather surprised to hear the matter brought up.

A lengthy discussion followed, and in which many of the members, including the Chairman, took active part. Many suggestions as to the means for remedying the condition of affairs alleged by Mr. Rogers were offered. Mr. Odell very aptly remarked that he would suggest that each member constitute himself into a committee to enthuse himself! (Laughter and applause!)

The Chairman ruled that the matter be referred to the incoming Council and that it be left with them to appoint any necessary committees to deal with the question.

Upon motion, the meeting was adjourned.

HYDRO-ELECTRIC POWER-STATION AT CHESTER, ENGLAND.

A novel hydro-electric station was not long since put in operation on the River Dee at Chester, Eng. Nearly 1,000-h.p. of electrical energy is being derived from a waterfall whose maximum head is 8 feet. The station was built by the Corporation Electricity Supply Department, who had to face the fact that twice a year at least the tidal bore of the Dee would reduce the head of water to only a few inches. However, upon working out the prospects of the scheme, it was found not only that the tidal bore exerted its influence at midday and midnight, times when electricity is little in demand, but also that the available power was least during the summer months, also a time when the demand for electric power is lightest.

The station is built on the site of the old Dee mills, which existed since Norman times until 1910, when they were finally purchased by the Corporation and pulled down. It was thought that the usefulness of the water at the weir for power purposes was at an end; but, upon the suggestion of the city electrical engineer, the possibility of using the water-power for electricity supply was investigated.

The old weir is built diagonally across the river at the east side of the old Dee Bridge, and practically forms a channel to conduct the water to the power-station; and, in this channel, sluice-gates and a strainer-rack have been placed. Below the weir the river is tidal, so that a specially-designed plant has had to be adopted capable of working efficiently over a wide variation of head and, consequently, of speed. The amount of power developed at any time depends upon the height of the river above the weir, which is, of course, a function of the rainfall, and the height below the dam, which depends on the state of the tide. It is calculated that these two factors will give average heads as follows:—

	Feet.
December	4.5
January, February, and March	6.25
April, May, October, and November	7.5
June, July, August, and September	8.75

The Electricity Committee has undertaken that in the working of the installation the water in the river above the weir shall not be lowered more than 6 inches below the mean height of the weir.

The new station, which has already been constructed, has been furnished with an installation of machinery, which, it is estimated, will yield about 1,250,000 units a year at a cost including capital charge of somewhat less than .3d. (or 3-5 of a cent) per unit.

A higher horse-power than that developed by any other vessel in the world will be one of the features of the new battle cruiser "Tiger," which has been launched at Clydebank, Scot., recently. It is unofficially stated that the engines will develop shaft horse-power, which means a speed of at least 31 knots.

A METHOD OF STRENGTHENING ROOF TRUSSES.

A NOVEL method of strengthening the roof trusses of a large public building was recently carried out satisfactorily by a Toronto engineer. The trusses, which are Howe trusses with wood chords and diagonals, and steel verticals, were of fairly good general proportion and make-up. The connections were inadequate, however, and the trusses had sagged considerably. The problem was to effect repairs in place, without disturbing either the ceiling, hung from, and partly resting on, the bottom chords, or the roof trusses which rest directly on the top chords.

The trusses (see Fig. 1) are 60 feet in length with depth of 8 feet centre to centre of chords. Both top and bottom chords are of uniform section throughout, the top chord being 7½ x 11½ in. and the bottom one composed of 4 pieces 1¾ x 12 in. The bottom chords are not spliced and have in some places two joints close together, so that the net value of the bottom chord (and this is near the centre of the truss) is not more than 2 pieces 1¾ x 12 in., equal to 42 sq. in. The diagonals are 6 x 8 in. throughout and the verticals are of round rods, 1½ in. diameter, not upset. There are 8 panels, but only 3 loading points located at the centre and at quarter-points. At the quarter-points the rods project downwards, through the bottom chord, to which they are not fastened, to carry lower side panels of the ceiling. At loading points there the 8 x 8 in. posts, the rods passing through these.

Loading is on the top chord from the roof, and though apparently on the bottom chord from the ceiling joists, it was found to be carried fully by the top chord. The trusses sagged at the centre, to a maximum of 3½ in. Some of the diagonals were found loose, showing that they took no weight; the arching of the roof, tied by indirect cross joist system, evidently taking the load.

Reinforcing was effected mainly by means of two wrought iron suspender rods for each truss, the rods being 1½ in. square, with each rod in three parts, centre and two ends, attached to pins at top chord ends and held together by Cleveland turnbuckles engaging upset ends. The pins are 2 in. in diameter, with pin plates, one on each side of top chord, 10 x 12 x ½ in. The top chord is reinforced throughout by two pieces of 2 x 10-in. pine, one on each side, bolted on by means of ¾-in. through bolts, spaced, staggering about 2 ft. The bottom chords are spliced by means of 2 x 12-in. pine pieces attached with ¾ x 9-in. lag screws. The reinforcing rods take bearing at the loading points, on shoulders formed by 2 x 8-in. pine pieces, one on each side of the post. Two pieces, 2 x 6 in., one on each side of truss, form struts resisting the side thrust, due to inclination of the rods at the quarter-point supports.

The rods and other reinforcing material were put in place practically without disturbing anything, in the space between the ceiling and roof. The 6-inch play in the turnbuckle for adjustment enabled the straightening up of the trusses, i.e., elimination of sag, as far as desired.

After this was done the top chord reinforcing was completed and given good abutting joints throughout, all vertical rods drawn up tight and diagonals brought to bearing, so that, although somewhat indeterminately, both the old truss and the reinforcing system will do work, in carrying the loading.

Without prejudice, it may be said that this class of work, viz., reinforcing of a truss or other member of a structure after it proves inadequate to do the work assigned to it by the architect or builder, is not an uncommon experience with engineers. The rational method is to have a competent engineer design the structure in the first place.

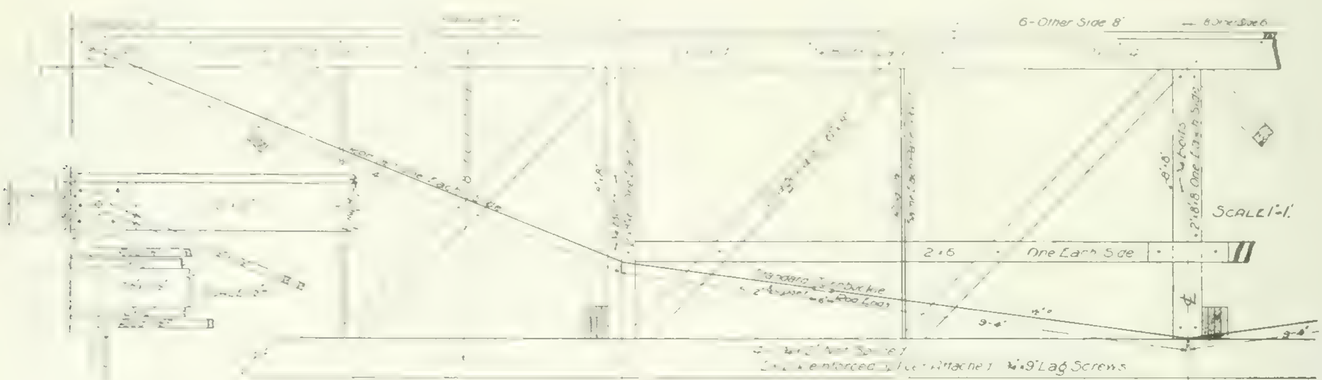

Fig. 1.

The statement of the Public Utilities Commission recently published, giving the condensed earning report of the Manitoba Government telephones for the 12 months ending November 30th, shows the revenue to have been $1,707,149.74; expenses, $1,269,909.90; net earnings, $437,239.84; interest charges, $406,975.20; and a resulting surplus of $30,264.64.

A cable sent from London to the New York Tribune not long ago reported the following in connection with a new invention in wireless science: "The newest development in wireless telegraphy was demonstrated at the exhibition of the Physical Society of London in the Imperial College of Science. This invention aims at the detection of direction from which a message comes. No one has yet discovered how to send wireless rays like a searchlight in any definite direction. They go out everywhere, but, even though they cannot be directed, it is just possible that a ship will be able to find out whence they come. This is done by a wonderful new instrument shown by the Marconi company.

According to the estimates which have been prepared by the Provincial Department of Mines, the total mineral production for the year 1913 will be slightly less than $30,000. The value of mineral products for the last year will be approximately $29,555,000, which is nearly $2,500,000 less than the production for the previous year. This decrease is due to a shortage of $1,600,000 in the coal mining industry occasioned by the labor troubles on Vancouver Island during the summer, and a shortage of about $656,000 from the metalliferous mines, due to a decrease of some $1,160,000 in the copper output and $25,000 in zinc which are, however, partly compensated for by increases in the output of gold, silver and lead.

CONTENTS OF THIS ISSUE.

RETROSPECT OF THE 28th ANNUAL MEETING.

The attendance of members at the recent Annual Meeting of the Canadian Society of Civil Engineers was probably the most representative in its history. There were in attendance prominent engineers from all portions of Canada and not a few from across the border to the south.

There was noticeable a distinct effort on the part of the Officers and Members of Council to restrict the proceedings to matters of first importance to the profession and its development.

Of the reports submitted, the most important was that in relation to Reinforced Concrete. No final action could, of course, be taken on a first consideration of the report. It will be referred to the branches of the Society, and to the membership at large, for discussion and at the next Annual Meeting it should be in form for adoption. It will constitute an advance on the present progress of the art which all concerned will, we are assured, greatly welcome.

The most prominent feature of the meeting was perhaps an indication of the desire on the part of the Council to get into more intimate touch than has hitherto been possible with the needs of its members. The recent effort to amend the by-laws in such shape as would advance the status of the profession generally in Canada will be noticed by anyone reading carefully the general remarks in the Report of Council, and it is to be regretted that while the membership at large undoubtedly favor the proposal to establish Provincial Divisions, the circumstances referred to elsewhere intervened to prevent the attainment of that end.

The recommendation that the business meeting of the Society should be held at headquarters is doubtless one which will commend itself to the business instincts of the engineering profession, while all will heartily approve of the proposal to develop the feature of summer meetings. The undertaking to hold such a meeting on the Pacific Coast at the earliest opportunity is one which will be heartily endorsed by all the members. This excursion would follow as closely as possible the opening of one or both of the new transcontinental routes and will be held in conjunction with the Panama Exposition and the series of engineering conventions to be held in San Francisco in 1915.

While, as always occurs in healthy growing institutions, there were some minor differences of opinion which developed as between members holding different points of view, the feeling was again and again expressed of hearty appreciation of the work of the Council of the Society and its efforts towards the consolidation of the profession as a whole.

The address of the retiring President, which we publish in full on another page, deals to a greater extent than is usual with Society affairs and we commend it to all members for serious reading.

THE QUESTION OF PROVINCIAL DIVISIONS.

It will be noticed from our report regarding the result of the ballots for amendments to by-laws of the Canadian Society of Civil Engineers, canvassed at the recent Annual Meeting, that an effort to establish Provincial Divisions within the Society was not successful. This failure seems to have been due to the disinclination of the British Columbia members, who mainly advocated

the proposal, to accept the by-law in regard to Provincial Divisions drawn up by the Council. The alternative by-law submitted by the British Columbia members differed from that proposed by the Council in minor matters only, the chief of these being that the British Columbia members desired to impose a fee of $1 on all members resident in the Province.

While we do not wish to enter into a discussion as to the merits of a proposal to establish Provincial Divisions, it would undoubtedly have been an act of wisdom on the part of those desiring them to have refrained from giving the membership an opportunity to split their votes, and the first effort should have been limited to a decision as to the principle involved, leaving the adjustments of details to the future. A resolution adopted at the close of the meeting recommitted this matter to the Council, and the question will no doubt be put, possibly in a modified form, before the membership with a view to amending the by-laws at the next Annual Meeting.

LETTERS TO THE EDITOR.

Ottawa Water Supply—Reply to Mr. Pitcher.

Sir,—In your issue of January 15th Mr. F. H. Pitcher, of the Montreal Water and Power Co., argues that the City of Ottawa might better filter and pump the Ottawa River water instead of putting in a gravity water supply from the Gatineau Lakes.

Mr. Pitcher argues that a filtration plant of the mechanical gravity type can be put in for $550,000, and that by erecting this proposed plant the city would save $7,450,000 out of a proposed $8,000,000 expenditure.

Granted that he is right in his estimate of the cost of the filtration plant, his cost comparison takes no account of the cost of operation and maintenance of the proposed filtration apparatus over that of the proposed gravitation system; neither does it take account of the cost of operation, depreciation and maintenance of pumping machinery.

Town Engineer.

New Glasgow, N.S., January 19th, 1914.

* * * *

The Billings Bridge at Ottawa.

Sir,—I read with interest the account of the proposed highway bridge for the City of Ottawa in *The Canadian Engineer* of January 29, 1914. Permit me to offer some kind criticism concerning the same.

It seems a shame to build a bridge with the steel work built to good heavy specifications and to have such a light floor slab. The floor slab is given as 4½ in. deep and apparently about a 4-ft. span.

Considering the specification of the Ontario Highway Board, which is regarded as good general practice, the slab holds good for only a 1-ton motor truck loading, if we assume that the wheel load is distributed over an area of 2 x 2 ft. (which is really too liberal an assumption). A 1-ton motor truck (Gramm) weighs 4,500 lbs., which, with the live load of 2,000 lbs., totals 6,500 lbs. The dead load is distributed equally over the four wheels while the live load is carried on the rear wheels. This gives a rear wheel load of 2,125 lbs. A 5-ton truck (not an uncommon load nowadays) gives a rear wheel load of 7,600 lbs., which would necessitate a slab of 5 in. effective depth if we assume the 2 x 2 ft. distribution, or 8 in. if we assume a distribution of 1 x 1 ft. (which is more nearly the actual condition).

The question of modern loading for highway bridges is one that demands the attention of all designing engineers. There was a time when the road roller produced maximum stresses, but to-day we have operating upon our highways many motor trucks that produce much larger stresses than the largest road roller. The bridges must be built heavy enough for these trucks or we will impose upon our country a grave barrier to progress.

A BRIDGE ENGINEER.

Toronto, January 31st, 1914.

Inquiry re Ice Pressures, and Flow of Water in Pipes and Chambers.

Sir,—Kindly allow me through the columns of your valued paper to obtain the following information:

What is the best formula as used in modern practice where very close computation is necessary for:

(1) Flow of water in pipes of various materials as required for water supply and power development inclusive of small pipes to penstocks attaining 20 ft. in diam.?

(2) Flow of water in channels inclusive of small sewers to water conduits attaining 20 ft. diam., the latter with only the necessary head to produce full bore flow?

Ice Pressure.—Having ascertained from particular conditions existing on a river as to probable maximum amount of ice in cu. ft. which can come down in mass, also the velocity of approach:

(3) What is the formula for finding the pressure exerted per sq. ft. on a vertical surface such as a solid dam or pier? Is the centre of pressure located at the centre of gravity of ice sheet?

(4) What is the formula for the pressure against the same surface exerted during the formation of ice per sq. ft., which would be the only pressure caused by ice on a large storage reservoir or dammed lake?

(5) Must allowance be made for the total pressure exerted by a season's formation or only for amount of ice formed during the maximum period of lowest temperature prevailing?

(6) What is the crushing strength of the best average ice formed on Canadian rivers?

(7) Are there any reliable works dealing with ice pressure and where can they be procured?

Any information on the above will be deeply appreciated.

AN ENQUIRER.

Montreal, January 24th, 1914.

Concerning the annual banquet of the Canadian Society of Civil Engineers, "La Patrie," Montreal, had the following to say: "The Canadian engineers who had their annual banquet last evening are men of actions and not of words. They made this evident in their very excellent and very brief speeches. There was not one speech of more than five minutes' duration and each speech produced a better impression than the windy eloquence to which we are accustomed under similar circumstances."

FIXED CARBON TEST AS APPLIED TO ASPHALTS

SUMMARY OF ARGUMENTS PRO AND CON THAT HAVE APPEARED IN THESE COLUMNS—A LETTER FROM FRANCIS P. SMITH, PH.B., M.A.S. C.E., A PROMINENT CONSULTING CHEMIST AND TESTING EXPERT

Sir,—The extended discussion in your columns on this test has greatly interested the writer and it occurs to him that at this time a resumé of the arguments for and against this test may be of value to your readers. He considers it only fair to state at the outset that in his opinion it is purely an identification test and has nothing whatever to do with the fitness or unfitness of an asphalt for paving purposes

In order to intelligently discuss the matter, it is first necessary to understand clearly just what this test really is. In his own experience he has found that there seems to exist considerable confusion in the minds of a number of engineers on this subject. In many instances it has been confounded with the free carbon test used in the examination of coal tars, although in reality it is a totally different test. In order to clear this matter up, even at the risk of repeating much that has already been said, the writer begs to call attention to the definitions of these two terms which have been adopted by the Committee on Nomenclature of the American Society for Testing Materials. These definitions are as follows:—

Free Carbon in tars is organic matter which is insoluble in carbon disulphide.

Fixed Carbon is the organic matter of the residual coke obtained by burning hydrocarbon products in a covered vessel in the absence of free oxygen.

It is evident from the foregoing that *free carbon* exists as such in tars. It can be isolated and determined by the simple process of dissolving the tar in carbon disulphide. By this treatment the free carbon, which is held in mechanical suspension in the tar and exists as a very fine powder resembling lamp black, remains unaffected by the solvent and may be filtered out and weighed.

The *fixed carbon*, on the other hand, is determined by burning the material in the absence of air in a prescribed way and for a fixed and arbitrary period of time. The mixture of coke and ash left is then weighed and the amount of coke determined by burning it off until nothing but the ash is left. After deducting the weight of the ash, the per cent. of coke is calculated on the basis of the pure bitumen contained in the material under examination.

The coke obtained in this manner is, of course, procured entirely by burning the material and does not exist at all in the original substance. Take, for instance, any pure asphalt and it will dissolve completely in carbon disulphide. If it contained any coke, this coke would not dissolve and yet when the same asphalt is burned under certain conditions coke will be formed just as it is formed by the incomplete combustion of coal. The fixed carbon test was originally devised solely for the examination of coal and for the purpose of showing approximately what proportion of carbonaceous material available for the production of heat will remain after the lighter and more volatile hydrocarbons have been burned off. This is concededly a useful and important test for solid fuels but all modern paving specifications contain special provisions to prevent the burning of bituminous paving mixtures *so that it is hardly logical to consider them as coming under a fuel classification.*

The asphalts used in the paving industry differ quite widely in their composition and are really very complex materials containing a large number of constituents. To a large extent these constituents are the same in all asphalts but the relative proportions of them differ. These constituents may be divided into two classes; viz., impurities and pure bitumen. The impurities consist of mineral matter (sand, clay, etc.) and vegetable matter (twigs, sticks, etc.). Those which constitute the cementing material, (i.e., the pure bitumen), and which determine the value of the asphalt, are termed hydrocarbons, and these different hydrocarbons, when burned, yield varying amounts of coke or fixed carbon. The amount of fixed carbon produced by burning the asphalt will, therefore, vary in accordance with the kind and proportion of the different hydrocarbons present in the asphalt. For this reason the determination of the amount of fixed carbon in connection with other tests is of use in the laboratory in determining the source or origin of an asphalt.

If we knew just what hydrocarbons or combination of hydrocarbons were best suited for paving purposes the most we could do would be to determine theoretically what the fixed carbon content of an ideal paving asphalt should be. As a matter of fact, the identification of all these various hydrocarbons is not possible in the present state of our chemical knowledge and even if this difficulty were removed, we know from past experience that certain hydrocarbons which by themselves are worthless for paving purposes form, when combined with other hydrocarbons, some of our best paving asphalts. For instance, a paraffine flux which is low in fixed carbon would be useless by itself as a paving material and yet when combined with one or more suitable hard asphalts forms an asphalt cement such as has been successfully used in laying millions of square yards of asphalt pavement. Even with the good and bad hydrocarbons all identified, the question of their various combinations would make it mathematically impossible to theoretically predetermine useful limits for the fixed carbon contents of suitable refined asphalts or asphalt cements for paving work, as we would find both good and bad asphalts included in these limits.

In a large majority of cases asphalt cements are made by fluxing hard asphalts with a suitable flux. It frequently happens that refined hard asphalts which show over 15% of fixed carbon will, when fluxed into an asphalt cement of proper consistency and quality for use, show less than 15% of fixed carbon. Is the ban to be placed on them also or are they to be considered as coming within the approved class? It would certainly appear to the writer as being more logical to apply the fixed carbon test to the asphalt cement than to the refined asphalt. If the requirement is to apply to the refined asphalt alone, what is to prevent the manufacturer from fluxing the hard asphalt to a point where it shows less than 15% of fixed carbon and where its consistency is but slightly be-

low that required for paving work and designating the fluxed material as a refined asphalt? If all the theoretical and practical objections previously noted are to be disregarded, it is at least evident from the foregoing that if any limit is to be set as to the fixed carbon contents of an asphalt or asphalt cement the only proper and just data for determining such a limit is that which has been obtained from pavements laid with the various asphalts then and now in use. In this connection the following table, showing the amounts of fixed carbon found in the more commonly used paving asphalts and fluxes, will be of value:—

Bermudez	12 to 14 %
California	9.5 to 18 %
Cuban (Mariel)	13 to 14 %
Gilsonite	15 to 25 %
Grahamite	40 to 55 %
Mexican	15 to 19 %
Texas	13 to 16 %
Trinidad	10 to 13 %
Paraffine fluxes	2.5 to 4.0%
Semi-asphaltic fluxes	5.0 to 7.0%
Asphaltic fluxes	6.0 to 9.5%

Taking the asphalts which show less than a maximum of 15% of fixed carbon, we find that these include Bermudez, Cuban (Mariel), and Trinidad. The service record of all of these asphalts is sufficiently good to place them in the accepted class.

We next have the class in which the minimum fixed carbon falls below 15% and the maximum above 15%. These include California, Gilsonite, Grahamite, Mexican and Texas. The writer has had a very long and intimate acquaintance with the manufacture of California asphalts and the laying of pavements with them since the very earliest days of the industry. It is true that in the early days some California asphalt was produced showing 18% and even higher of fixed carbon. It must be remembered, however, that several grades are and were manufactured, some of them for paint and varnish purposes and these latter were much harder and necessarily higher in fixed carbon than the grades manufactured for paving purposes. In a number of cases when stocks ran low, as they frequently did in those days, the hard asphalt was shipped and used for paving work. The writer, moreover, has laid a number of pavements with just such asphalts and where they had not been cracked to such an extent as to destroy their solubility in fluxes and their cementing value, the pavements laid with them gave just as good results as those laid with asphalts lower in fixed carbon. In many cases the high percentage of fixed carbon contained in those California asphalts manufactured for varnish and paint purposes have been misleadingly quoted against California paving asphalts in general as showing their unfitness for paving purposes and the lack of care used in manufacturing them. It is history, however, that these very same carelessly manufactured asphalts, often showing high fixed carbon, proved so great a commercial success in the paving industry that the interests controlling the so-called natural asphalts attempted to control them in one vast organization. Since about 1895 gradually increasing amounts of pavements have been laid in the United States and elsewhere with California asphalt until at the present time there are many millions of square yards of pavements of this character in existence which are giving good service. There is no doubt but that a considerable proportion of the California asphalt manufactured between the years 1895 and 1900 showed over 15% of fixed carbon, but the writer is in a position to state positively that, having in mind the state of the art at that time, the average of these pavements gave just as good satisfaction as the average of the pavements laid during the same period with other asphalt showing less than 15% of fixed carbon.

Mexican asphalts normally run higher in fixed carbon than do most others. Pavements laid with this type of asphalt have been in use in Mexico, Canada and the United States for upwards of five years. A careful physical and chemical examination of them proves that they possess all of the qualities which are necessary and essential for laying a first-class asphalt pavement. They are almost 100% pure bitumen, are higher in ductility and cementing value than any others excepting the California, and are less susceptible to changes in temperature than any other paving asphalt of recognized quality. From the above data and the fact that they are produced by the same approved and time-tested methods and with the same care used in manufacturing the best California asphalts, which have proven so successful, the writer is convinced that there is every reason for including them in the list of paving asphalts of the highest quality.

Many thousand square yards of successful asphalt pavements have been laid with asphalt cement manufactured from Gilsonite. It is a fair statement to make that if the present price of Gilsonite were not so high, it would be much more widely used at the present time in the paving industry. Most of the Gilsonite available for paving purposes will show considerably in excess of 15% of fixed carbon. When fluxed with California residuum, the asphalt cement so produced will in most instances show less than 15% of fixed carbon. The service tests of pavements laid with asphalt cements of this character are undoubtedly sufficiently good to include them in the preferred class of paving asphalts. The use in the paving industry of asphalt cements made from Grahamite, which is very high in fixed carbon, has been limited, but a number of excellent pavements have been laid with this material.

Much of the so-called Texas asphalt as present upon the market will show less than 15% of fixed carbon. Occasional shipments of it, however, will run up to 16% or slightly over. Chemical and physical examination of the shipments showing over 15% of fixed carbon, together with the service records of pavements laid with them show that the high fixed carbon material is just as good as the low fixed carbon material. In fact, it is impossible to detect any difference between them. It would appear to be clear from the foregoing that, based on service tests alone, there is no reason for inserting a fixed carbon clause, or, if inserted, limiting it to a maximum of 15%. Such a maximum would limit the asphalts admitted to Bermudez, California, Cuban, Texas and Trinidad. Practically all of the present-day output of California asphalt would be admitted, together with a large proportion of the so-called Texas asphalt. Gilsonite, Grahamite and Mexican asphalts would be excluded. At the present time but small quantities of the first two asphalts are used in the paving industry, but the volume of Mexican asphalt produced in this country is very large and increasing very rapidly. From a commercial standpoint, its competition with Bermudez and Trinidad asphalts is more serious than that of any other asphalt. At the present time it is admitted under all of the standard open specifications now in force in the United States in most of the largest cities, so that it is reasonable to assume it to be of good quality. From the municipal standpoint, it is

exceedingly important that free and open competition in standard asphalts should be encouraged and maintained. From this point of view, it would be unfortunate indeed to bar out what is admittedly one of the most important factors in the asphalt situation to-day. The Mexican oil fields are concededly one of the largest, if not the largest, which have ever been developed and their supply is practically inexhaustible.

The old and artificial brand standard of judging quality is rapidly disappearing and in an attempt to preserve it in a manner which can not readily be detected, a large number of tests are being advocated under the plea that they are necessary ones. As a matter of fact, most of these tests are purely identification tests and are intended to limit the asphalts admitted under them to certain brands. It is well that municipal engineers should understand this matter thoroughly and be warned against it and only accept tests in their specifications which have been proven to be quality tests and essential in determining the actual paving value of an asphalt. It would appear, therefore, that the chief effect of a 15% fixed carbon clause would be to exclude Mexican asphalts. The authors of most of the articles which have appeared in your pages agree that asphalts produced from Mexican oils should normally show a high fixed carbon content. The strongest advocates of the fixed carbon test agree that its chief influence is to prevent an undue amount of condensation or cracking from taking place. In all asphalts produced, either by nature or man, a certain degree of condensation has taken place. It is only where this condensation is excessive that any objection can be raised to it. Asphalt manufactured from Mexican oil with all the care and precaution that years of experience has proved to be necessary will normally show over 15% of fixed carbon. From this standpoint, therefore, its exclusion is unjustifiable. From the laboratory standpoint its physical and chemical characteristics show it to possess in the highest degree the properties which have been found to be desirable and necessary in a paving asphalt. As to service tests, since 1911 over thirty thousand tons have been sold for sheet asphalt paving purposes in Canada and over sixty thousand tons in the United States. Disregarding entirely the favorable results of these service tests and the fact that it is being freely used in open competition with all other asphalts by most of our largest cities and in many municipal paving plants, it is unreasonable to assume that any such quantity of it could have been sold if it were an inferior asphalt. Contractors would have refused to bid upon it and assume maintenance guarantees. The strong inference is, therefore, that the opposition to its use is purely a commercial one.

One of the arguments which have been used in favor of the fixed carbon test is that while it may bar out certain good asphalts, it safeguards a municipality by insuring the use of only such asphalts as are suitable for paving purposes. From the standpoint of the fixed carbon test only this is not true. A great many blown asphalts which are not recognized as being suitable for paving purposes show less than 15% of fixed carbon. In fact, it is probably fair to state that taking 15% of fixed carbon as the dividing line, there are more poor asphalts showing less than 15% of fixed carbon than there are poor asphalts showing more than 15% of fixed carbon. It is apparent, therefore, that the fixed carbon test *per se* is not sufficient to insure a good paving asphalt, but that this can only be done in connection with other tests. If these other tests are sufficient to exclude the large number of poor asphalts showing less than 15% of fixed carbon, it is certainly logical to assume that these same tests will be sufficient to exclude poor asphalts showing more than 15% of fixed carbon. From this standpoint alone there would appear to be no reason why a fixed carbon test of any kind should be included in a specification for paving asphalt.

Certain points have been raised in the articles which have been published in your pages which appear to the writer to call for further comment. In discussing Mr. Pullar's paper,* the writer wishes it to be distinctly understood that as a whole his experience confirms most of the facts stated by Mr. Pullar, but that he is not in accord with the conclusions drawn by him from these facts.

Mr. Pullar, in his article, states that the ductility test in the hands of different chemists gives more widely varying results than does the fixed carbon test. The writer and his partner have probably had a greater experience with this test than anyone else and he thinks it only fair to state that when the standard method is followed the variations stated by Mr. Pullar are far too great. Assuming, however, for the sake of argument, that the ductility of the same sample was reported by two different chemists as 90 cms. and 70 cms., respectively, both of these results are so far above the usual minimum requirements for ductility that the sample would be unhesitatingly accepted as passing the requirements in this respect.

As a matter of fact, the variation in different results on the ductility test is no greater than on the fixed carbon test and all the widely known and used standard paving asphalts have a ductility far in excess of the usual minimum limit given by specifications (20 cms.), so that the allowable variation would not work a hardship on any of them or cause them to be excluded. This is shown by the following table giving the average range of ductility for cements of 50 penetration made from the asphalts mentioned in the previous table of fixed carbon contents:

Bermudez	40 to 70 cms.
California	90 cms. and over
Cuban (Mariel)	20 to 30 cms.
Gilsonite	20 to 50 cms.
Grahamite	15 to 30 cms.
Mexican	50 to 100 cms. and over
Texas	50 to 100 cms. and over
Trinidad	35 to 60 cms.

The writer has gone into the matter of the ductility test at the present time more especially because this test is employed in almost all specifications and amply guards against all undue blowing of asphaltic products.

In this connection Mr. Pullar quotes tests on a number of blown products made from Ohio and other oils. In the first place, blown products of this class are not generally considered as suitable for paving purposes and certainly not when made from Ohio oil *per se*. Products of this character would not be admitted under any of the standard paving specifications. The instances cited would, therefore, appear to have little or no bearing upon the value of the fixed carbon test for paving specifications. As a matter of fact, it is easier and cheaper to produce a blown asphalt from Mexican oils which will show less than 15% of fixed carbon than it is to produce from them a paving asphalt of good quality and high ductility that will normally contain from 15 to 17% of

*"The Value of the Fixed Carbon Test," *The Canadian Engineer*, November 13th, 1913.

fixed carbon. If the ductility test in the usual open type of specifications were eliminated and the fixed carbon test substituted, any manufacturer could cheaply and easily make an inferior product from Mexican or other oils that would meet the specifications. This could, of course, be prevented by introducing a number of additional tests, but why cumber the specifications in this way and make them still more difficult for the average engineer and contractor to understand when a ductility test answers every purpose?

Mr. Pullar further states that a poor quality of fluxing oil will show up by high fixed carbon in a fluxed asphalt. This statement requires very considerable modification. For many purposes fluxes made from asphaltic oils are superior to those made from paraffine oils and yet the former are higher in fixed carbon. A relatively high fixed carbon in a fluxed asphalt would, therefore, in many instances indicate a better product than a low fixed carbon. Where the fluxed bitumen was a very hard one and was only partly soluble in a paraffine flux and wholly soluble in an asphaltic flux, Mr. Pullar's statement would, of course, be entirely correct, but when the hard asphalt was equally soluble in both kinds of fluxes and relatively the same amount was used in each case, the product made with the asphaltic flux would show the higher fixed carbon.

The writer strongly disagrees with Mr. Pullar that the majority of so-called open specifications are so faulty as to permit the use of undesirable material. It is his experience that under them better asphalts are being supplied than for years past and that the practice of dividing bituminous material into various classes is a cumbersome, confusing and useless one. His views on this particular subject are quite fully set forth in a previous issue of your paper; page 175, Jan. 15th, 1914.

Much has been written against the so-called "cracking" of an oil during the manufacturing process and that this necessarily injures the paving value of the asphalt and that this also is shown by the fixed carbon test. The writer is of the opinion that so long as the essential physical qualities of the product are not injured, cracking *per se* is not necessarily injurious. This may appear to be a somewhat revolutionary doctrine, but in many instances he and others have successfully used cracked products so long as their stability and cementing value had not been injuriously lowered, and in the early days of the paving industry practically all the fluxes were cracked products and they often formed 25% of the asphalt cement used.

Coal tar has long been successfully used in the paving industry and it certainly is a much cracked product, notwithstanding which it will retain its original consistency longer than asphalt and is certainly equal to it in cementing value, even though it frequently shows 30% or more of *fixed carbon*.

Mr. Kirschbraun's article* is an exceedingly able and interesting one. The writer believes, however, that his formula (based on the crude used) for determining the allowable amount of fixed carbon in an asphalt does not sufficiently take into consideration the variation in fixed carbon contents produced by different methods of distillation. This is indicated by the California asphalt mentioned by Mr. Pullar as containing only 9.5% of fixed carbon against the normal range of 11 to 14% in asphalts made from the same class of crude. His table on page 803 of your journal illustrates that a California "B" grade asphalt showing 16.3% of fixed carbon may be converted into a bright ductile cement showing only 12.6% of fixed carbon by the use of a suitable flux. This accords with the writer's experience. No other tests are given on the cement by Mr. Kirschbraun, but the writer has made similar cements which were in every way suitable for paving use and has employed them in laying pavements which were in every way successful and permanent. This shows that when combined with a suitable flux, asphalts which have been cracked in distillation and have a high fixed carbon test, are not necessarily injurious or unfit for paving *providing they have the other necessary qualities of stability and cementitiousness.* Where one type of crude is being used and the same process of distillation is employed, the fixed carbon test will undoubtedly check up variations in the handling of the stills and it is concededly valuable for that purpose, as is also the carbon tetrachloride test. At times one of these tests will show variations which the other will not. Mr. Kirschbraun states: "It is apparent that the best practice should limit this action (condensation) to the minimum and that specifications should control this by a fixed carbon limit within which the product will retain to a useful and permanent extent the qualities necessary for pavement and road construction." Possibly the writer misunderstands Mr. Kirschbraun, but he fails to see how this could be done practically. First, we have the variation due to different crudes; second, the variation due to different approved methods of refining upon the same crudes; third, the influence of various fluxes on the asphalt cement; and fourth, the determination in each particular case of the amount and kind of condensation which is harmful. If the allowable percentage of fixed carbon is to be regulated in accordance with the qualities necessary for road or pavement construction, why not specify the permissible limits in these respects and omit the at least doubtful and variable fixed carbon requirement? The ductility test will always detect lack of cementitiousness due to improper manipulation or any other cause. Hence it accomplishes all that has been claimed for the fixed carbon test without any unfair discrimination.

Mr. Kirschbraun, in his letter appearing in your issue of January 29th, proposes that the minimum theoretical fixed carbon value characteristic of an asphalt of a given penetration made under ideal refining conditions should be determined by a laboratory run, the idea being to establish a fixed carbon standard for products made from a particular crude. Laboratory methods differ as much as do producing methods on a large scale and for this reason alone the proposition seems to the writer to be impractical. It also involves the assumption that any degree of condensation in the commercial product in excess of that produced by the laboratory method employed is harmful. This argument, if carried to the extreme, would involve the use of distillation processes conducted under less than atmospheric pressures, which the writer believes to be in most cases entirely unnecessary. In his own experience asphalt produced in this way has at times been found inferior to that produced in a commercial manner with a very considerable degree of condensation, in that the product made under diminished pressure was susceptible to changes in temperature to an undesirable extent.

Mr. Kirschbraun suggests an alternative clause in which he places a maximum of 13% of fixed carbon and a sliding scale whereby any increase in the fixed carbon contents shall be compensated for by an increase in the solubility of the material in carbon tetrachloride. This appears to the writer to be an attempt to use what he

* "Fixed Carbon Depends on Crude." *The Canadian Engineer*, December 4th, 1913.

considers tests of very questionable value to counterbalance each other.

Reverting again to the California asphalt mentioned by Mr. Pullar as containing only 9.5% of fixed carbon and assuming this to be a paving asphalt of high grade, why should any other California asphalt made from the same crude be permitted to have as much as even 13% of fixed carbon? Here, again, the question of the refining processes used becomes a very important matter in determining the allowable amount of fixed carbon, and no matter what limits as to fixed carbon and carbon tetrachloride solubility are determined upon, it becomes necessary to revert to other tests to safeguard the material to such an extent that the value of the fixed carbon test itself appears negligible.

Mr. Kirschbraun also suggests that if the chemist has no faith in the carbon tetrachloride test, this solvent might be replaced by carbon disulphide. The writer fails to see how this latter solvent could be of any value unless the material had been so far decomposed as to coke it. The products made from paraffine base oils are admittedly entirely unsuitable for paving purposes and yet these are the lowest in fixed carbon. Products made from asphaltic crudes of any sort are always higher in fixed carbon than those made from paraffine crudes. On this ground alone, therefore, it would appear to be more logical to limit the minimum amount of fixed carbon permissible in an asphalt than the maximum amount. In any event, other tests are required to determine the fitness of an asphalt, and, as previously stated, if these other tests are sufficient to discriminate between the good and bad materials having less than 15% of fixed carbon, it would appear that these same tests were also sufficient to discriminate between the good and bad materials having over 15% of fixed carbon. Why, therefore, use the fixed carbon test at all? From the standpoint of the inspecting chemist, the fixed carbon test undoubtedly has a certain value, but to introduce it properly into a specification so as not to discriminate against certain materials and yet have the provision of any use appears to the writer to be impracticable. He believes that a clause inserted in the ordinary open type specifications to the effect that all shipments of material shall be fully equal to the established standard and recognized quality of that particular brand will prove to be all that is necessary provided that the requirements as to cementing value or ductility, purity, susceptibility to changes in temperature and stability under heat are sufficiently high.

The writer agrees with Mr. Kirschbraun that the fact that the fixed carbon test was originally devised for the examination of coal does not necessarily mean that it is of no value in the examination of other materials, such as asphalts. He does not believe, however, that the authors of some of the articles which have appeared in your pages have objected to the fixed carbon test as applied to asphalts solely on the grounds of its origin. It appears to him that in view of the fact that the fixed carbon test as applied to coals is of value in judging them from the fuel standpoint, unless good and sufficient reasons are advanced to show that this test when applied to asphalts conclusively determines something entirely different, i.e., their suitability for paving purposes, it is wholly pertinent and logical to show that a test which has only been proven to measure fuel value has no place in an asphalt specification.

Mr. Law's paper* clearly shows the variations in results obtained by different chemists with the fixed carbon test and points out the cause for many of them. He also points out the absurdity of rejecting a material for being a few tenths of a per cent. in excess of specification requirements when the limit of accuracy of the method employed is less than the excess upon which the rejection is based.

*"Fixed Carbon Test Empirical."—*The Canadian Engineer*, November 20th, 1913.

Mr. Richardson's letter* ignores details entirely and proceeds upon the broad, and (to him) satisfying, assumption that all asphalts showing more than 15% of fixed carbon are inferior or experimental. This, the writer contends, is wholly unjustifiable and is not borne out by the experience gained during the past 15 years in the paving industry. It can not, therefore, be considered a very valuable contribution to the present discussion. Millions of square yards of pavements made with "residual pitches," as he terms them, have been and are being laid by his own company and others, and the results have proved that they are fully equal to pavements laid with the so-called natural asphalts which he advocates. Gilsonite has also been used in the laying of many successful pavements and much of this material shows over 15% of fixed carbon. So far as stability is concerned, all of the good asphalts made from asphaltic petroleum are more stable under heat than one of the asphalts which he advocates so strongly.

FRANCIS P. SMITH.

New York, January 31st, 1914.

*"Fixed Carbon Limitation."—*The Canadian Engineer*, December 18th, 1913.

MINERAL PRODUCTION OF ALBERTA FOR 1913.

As Alberta is the province with the greatest coal resources in all Canada, so it is developing rapidly as a producer of coal, the output for the year being estimated at about 3,500,000 tons, or nearly half the production of Nova Scotia, the oldest and largest coal-producing province. During the year thirty new coal mines were opened. The International Coal and Coke Company was the largest producer of both coal and coke, and distributed $30,000 a quarter in dividends, being equivalent to 1 per cent. per quarter. The Canadian Coal Consolidated Company, of Frank, was practically closed down this year, the production amounting to 13,958 tons. The Hillcrest Collieries at Hillcrest produced over 300,000 tons. The city of Lethbridge runs the Lethbridge City Mine, which produced about 21,750 tons. The Diamond Coal Company closed down their mine on June 1st, up to which time the mine had produced 17,503 tons. The mines in the North and through the Yellowhead Pass experienced a quiet year.

The production for the year is estimated as follows:—

Coal, 3,500,000 tons	$ 8,750,000
Coke, 100,000 tons	660,000
Cement and building materials	2,500,000
Natural gas	1,875,000
Total	$13,775,000

Venice, Italy, has appropriated $20,000 to investigate the advisability of building a highway tunnel of 11,800 feet between that city and the islands of Giudecca, San Giorgio and Lida. If this investigating body reports that the plan is practicable, such construction will mean the passing of the picturesque gondola system of transportation. If the project is carried out the tunnel will be the longest highway tunnel in the world.

PROGRESS ON THE MOUNT ROYAL TUNNEL.

DURING the recent Annual Meeting in Montreal of the Canadian Society of Civil Engineers, the Mount Royal Tunnel and Terminal Company fittingly recognized the large assembly of Canadian engineers in (1) an invitation to visit and proceed through the tunnel—an opportunity which was largely taken advantage of by the members; and (2) the circulation of a 50-page booklet descriptive of the project and the methods adopted for the carrying of it to a speedy and successful conclusion. This pamphlet contains in concise form a great deal of value in the way of information on the subject of tunneling, and we strongly feel like recommending our readers interested in the same to write Mr. S. P. Brown, Chief Engineer, Mount Royal Tunnel and Terminal Co., Montreal, for copies for themselves.

The major portion of the reading matter, and many of the illustrations have been published in past issues of *The Canadian Engineer*, but the notes on the progress of excavation work, extracted below, have not previously appeared. Before beginning this, however, our readers are referred to the following articles for more complete information respecting the planning and carrying out of this project:—

Fig. 1.—General View at the West Portal, Showing Plant and Tunnel Entrance as Seen at Present.

(1) A general description of the scheme, giving proposed location of tunnel and terminals; description of compressor plant, shops, and adopted methods of excavation, was published in *The Canadian Engineer* for January 16th, 1913.

(2) Additional data and numerous photographs, describing in detail the mechanical arrangement of plant and outlining the lines upon which drilling operations were conducted, was contained in *The Canadian Engineer* for February 6th, 1913.

(3) An article on the precise survey and measurement work, prelminary to the commencement of actual boring, by Mr. J. L. Busfield, assistant engineer, Department of Surveys and Alignment, appeared in *The Canadian Engineer* for February 27th, 1913.

(4) In our June 12, 1913, issue, announcement was made of the record in drilling which had been established during the month of May.

(5) July 10th, 1913, issue contained a description of the cross-section which had been adopted for the tunnel, and the factors attending the choice.

(6) The system of electrification decided upon was described in *The Canadian Engineer* for October 9th, 1913.

(7) A description of the electric locomotives to be used, together with equipment for control and operation, appeared in our issue of December 4th, 1913.

(8) An article by Mr. Busfield, on the underground survey work which was responsible for such a successful meeting of the headings, was published in *The Canadian Engineer* for January 22nd, 1914.

Geological Conditions of the Tunnel.—According to publication referred to above, Mount Royal, about 700 feet high, is the result of a volcanic intrusion of igneous rock forced upward through the original bed of Trenton limestone. Whether it was ever an active volcano is doubtful, as there is little evidence of lava, although it may have been scoured away by glacial, or other action, at the same time that the higher portions of the mountain were similarly eroded. There have evidently been several stages of eruption or intrusion, as both the limestone and main igneous body of so-called Essexite are broken and cut by a multitude of dikes and sheets of quite different character and evidently later origin. The trenton limestone, at a considerable depth, is found to be hard and crystalline, and is an excellent rock for tunneling. This rock, when in close proximity to a large igneous body, is sometimes highly impregnated with epidote, quartz, garnet, and other minerals.

At the city end, going west from Dorchester Street, the heading for the first 2,000 feet is in a soft black limestone, somewhat blocky and in places partially disintegrated, with occasional stretches of earth roof. The earth, above the limestone, consists of sandy clay, boulder clay, occasional layers of hard pan, fine sand and large bodies of blue leda clay. This being under the city proper, forms the most difficult ground and conditions to be encountered, and a roof shield will be used.

As the rock cover increases the rock becomes harder and more dikes of extremely hard igneous rock are encountered. By the time 3,000 feet of heading had been driven, from Dorchester Street, the heading (except for the dikes) was in good, sound Trenton limestone, becoming more crystalline. It was in this that the record progress was made.

The greatest difficulty encountered in drilling and excavating is due to the irregularity of the structure. Some of the limestone is so impregnated with various contact minerals that it is extremely hard to drill and some breccia is so broken and uneven that in places one hole would be lost out of three started. The worst trouble, however, occurred when large dykes were encountered which necessitated entirely changing the temper of the steel used; for instance, in the heading going east from the West Portal a dyke of porphyritic Camptonite, an extremely hard rock, four feet thick, continued in the face for 400 feet. Here two tempers of steel were required in the heading all the time. This greatly retarded the progress and materially increased the cost of excavation.

Another very difficult rock is a marmorized limestone that was found in one of the headings. This marble is impregnated with quartz and a natural cementing material that makes it hard to drill and causes the muck to set up so rapidly that it is very difficult to shovel into the cars.

In general, the Trenton limestone is an excellent tunneling rock although the roof is sometimes inclined to scale badly and where this ground is cut by dykes the tunnel walls are apt to be insecure. When this limestone

is badly distorted by neighboring igneous intrusions it is apt to be filled with internal strains which cause it to crack and fall making it rather treacherous and requiring heavy timbering and masonry lining.

Often, especially in the limestone, cavities are found filled with calcite crystals of both the dogtooth and nail-head pattern. Here, too, is found a good deal of saponite and pyrites in various forms. Considerable Dawsonite, Feldspar, metallic arsenic and gypsum have been found from time to time, but not in quantities to be commercially valuable.

Heading Excavation.—Time being of vital importance in the Mount Royal Tunnel, it was decided to adopt a bottom centre heading which could be driven ahead rapidly, without much regard for the character of the ground, and from which the full-sized excavation could be developed at as many places simultaneously as desired. The headings are driven 8 to 10 feet high by 12 to 14 feet wide (over 50% larger than the headings of the principal Alpine tunnels) for the sake of ultimate economy. While this somewhat reduces the rate of progress, it very much decreases the cost of further excavation and construction; permitting reasonably broad-gauge double track through the break-ups, where the full size tunnel section, 22 feet high by 30 feet wide, is developed.

In the headings three principal methods have been used. In the method where the rock was not so hard as to require an excessively heavy drilling equipment, the drills are mounted on a horizontal bar and the equipment is handled in and out of the heading by hand. During this stage at the city end the heading cross-section was reduced to about 8 by 12 feet for the sake of rapidity in progress. Here no drill carriage was used, as much lighter drills were required, and a progress of 810 feet was made in the 31 working days following May 1st. This is the greatest linear progress ever made in a hard rock heading on this continent and has only been exceeded in Switzerland.

Four drills are used in each heading, supported on a horizontal bar. These drills are operated by compressed air at about 100 lbs. pressure per square inch. Each drill is fitted with special connection so that water may be forced through the piston and drill steel, which are hollow, into the bottom of the hole being drilled, thus keeping it cool and clean.

It is also interesting because both the linear feet of drilling (about 650 feet per 24 hours) and cubic yards of excavation (93 cubic yards per day) exceed anything ever accomplished in the European tunnels.

As the headings got into the hard igneous rock heavier drills were required, so that the total drilling equipment, including drills, saddles, arms and bar, weighed several tons. To carry this mass two types of drill carriages were devised. Each carries the drill bar on a long cantilever arm having a reach of over 20 feet beyond the carriage and is so arranged that the drills never have to be dismounted from the bar nor disconnected from the hose-manifold which is fastened to this cantilever arm. Thus the only connections to be made, when moving out or setting up, are the main air and water hose to the pipe lines entering the heading, and the only labor is that of jacking the horizontal drill-bar tightly into position after it has been brought in and placed by the drill carriage.

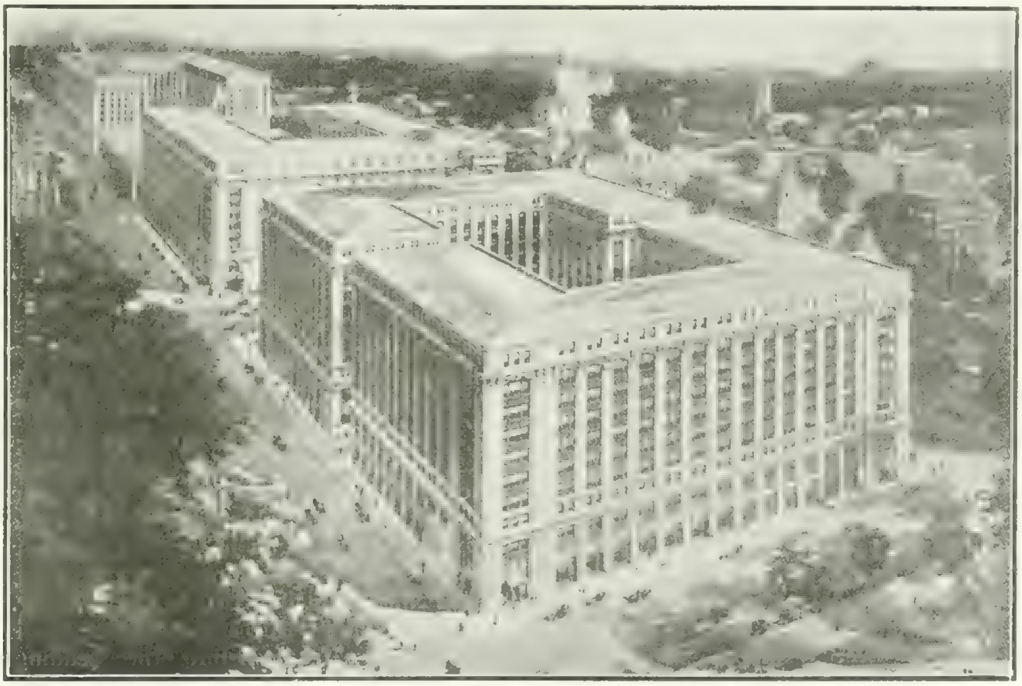

Fig. 2.—Proposed Buildings for the C.N.R. Passenger Terminal, Montreal.

All drill carriage track is riveted to steel plates so that the track may be cleared rapidly to within about 25 feet of the face after each shot, merely throwing the muck right and left. In the case of the muck-handling drill carriage the track is laid on one side of the heading while the other has its track down the centre. These machines save wear and tear on both men and machines, and make a surprising difference in the efficiency of both. With these machines the drills are in the heading ready to be jacked into place by the time the drillers have the loose rock barred down from the sides and roof and the muck thrown back sufficiently from the face to enable the bar to be set. Thus the time spent in setting up and taking down is much reduced. It is also notable that less muckers are required with this system than before the drill carriages were installed.

One drill carriage is so designed that the cantilever arm is given its motion, longitudinally, transversely and vertically by motor-driven attachments. This machine remains in the heading after the drills are placed and has a belt conveyer running through it longitudinally about 18 inches above the track, which elevates and dumps the muck into cars in the rear. This was used in one of the headings, as shown in Fig. 3.

The effect of installing the muck-handling drill carriage is shown to a remarkable degree by the difference in progress obtained without any increase in force. For the six months prior to its installation the average progress in this heading was 350 feet per month. For the six months after the installation of the drill carriage the average progress has been 485 feet per month. This is an increase of 38%. Furthermore, it must be remembered that before the drill carriage was installed the heading was in limestone, for the greater part, while the drill carriage has been working almost exclusively in Essexite. The best month, May, 1913, was 510 feet in 27 working days. This heading is 10 feet high by 12.5 feet wide.

The average yardage removed from this heading, including the 4 break-ups now working, is about 500 cubic yards, place measurement, per day. The linear progress in these break-ups is about twice that of the heading.

The other drill carriage used has no motor attachment and is removed from the heading after the drills are placed, leaving the cantilever arm attached to the drill bar and supported on a gallows frame which leaves the heading open for mucking, as shown in Fig. 4. In this case the cantilever arm is advanced by the locomotive which pushes the drill carriage into the heading. The lateral and vertical movement are obtained by jacks and by hand. The progress with this carriage is almost identical with that of the other.

The average progress over the entire job since the headings were started in the tunnel has been 420 feet per month in each heading. This makes no allowance for delays or lost time. It must also be remembered that for six months on the city end the blasting was restricted between the hours of 11 p.m. and 7 a.m. to avoid public annoyance. The average progress, where blasting has been unrestricted, has been 430 feet per month in each heading. From the time the first heading was started in the tunnel until the final meeting almost exactly fifteen months have elapsed, giving a gross progress of 1,100 feet per month.

The general heading procedure is as follows:—

After a round of blasts has been completed the loose rock is barred down from the roof and sides and the muck (i.e., the broken rock) is thrown back from the face sufficiently to permit the horizontal bar and drills to be set up. These are erected, connected with the air and water lines and drilling commenced. From 18 to 24 holes, 5 to 8 feet deep, are drilled in the heading. In the meantime the muckers have cleared the tracks, and are shovelling the muck into the cars, or onto the conveying belt where the muck-handling drill carriage is used. Smooth steel plates, called slick sheets, are laid in the bottom of the heading before each blast, for the muck to fall on, so that the muckers shovel off a smooth surface.

Where no drill carriage was used three muckers threw the muck back from the face to the slick sheets and four shovelled it into the cars. These four men, on each shift of 8 hours, handled all the muck made in that shift. Thus, during the record month, each man handled from 12 to 15 cubic yards of muck per shift, which, considering that about two hours of each shift were lost in blasting, was a most unusual performance.

All blasts are fired electrically from the lighting circuit; the blasting switch and leads being carried on the opposite side of the heading from other electric wires. Where time fuses are not used the rounds are usually fired in four shots; 1st, the cut holes, which form the opening wedge; 2nd, the relieving holes, immediately surrounding the cut; 3rd, the line holes, which break the heading to its full width; 4th, the dry holes, which break the heading to its full height. Sometimes the line holes and dry holes are fired together when the ground is breaking well.

When time fuses are used the cut is fired in the usual way with ordinary exploders so that if, as is very often the case, the cut does not break to the bottom at the first shot it can be fired a second time.

After the cut has been fired the rest of the heading is loaded with time fuses, cut at two-inch intervals, running in length from two inches up. Two of each length of fuse are used around the cut, the shortest fuses being closest to the cut and the longest being the two bottom corner holes so that the muck will be thrown back from the face by the last explosion. These fuses are ignited by electric igniters exactly similar in construction and resistance to the regular electric exploders. Thus all fuses are ignited simultaneously and regular exploders may be discharged at the same time if desired. This method saves time in blasting and leaves the men much fresher than if they had to go back into the smoke again and again. As all the fuses are very short the danger from cut-off holes is practically eliminated; in fact there has been no trouble from this source whatever thus far. This method is also used in all the break-ups.

In the heading a round of shots is fired from 3 to 6 times a day (24 hours). During the record month, with three exceptions, six shots were fired every day.

Break-up Excavation.—The break-ups (see Fig. 5), where the upper part of the tunnel section is excavated to its full width and height, are opened at intervals of 500 to 800 feet along the centre bottom heading. As many of these may be opened as are necessary to keep up with the heading progress, the advance in each break-up being about half that in the heading.

In making the break-up excavation heavy jumbo timbers are framed into the heading, about two feet apart and planked over, so that as the rock is blasted down from above, it can be run through the jumbo timbers into the muck cars in the heading beneath.

The break-ups are advanced by carrying an entry, about 15 feet ahead of the wing wall excavation, the same width of the heading and to the full height of the roof. A horizontal bar is used with 4 drills as in the heading. Immediately after shooting the bar is set up above the muck and the upper half of the entry is drilled. Then the bar is removed to the other end of break-up, and while the upper half of that entry is being drilled the muck is removed from the first entry. Thus when the upper half of the second entry is drilled the bar may be set up again in the first entry and the lower half drilled. By the time this drilling is finished the muck is removed from the second entry and the lower half of that may be drilled. In the meantime two columns with a single drill on each are set up in the wings and these drilled so that all the drilling is finished at the same time.

In the limestone two drilling shifts will break all the ground that three mucking shifts can handle economically. As the blasting is always breaking to two faces the drilling is comparatively light and very little powder

is required; the powder actually amounting to less than one-quarter that required in heading work. The blasting in the break-ups is done with time fuses which are ignited electrically. Thus it will be seen that the break-up excavation requires but little labor and explosive, being both rapid and economical. With four break-ups and one heading working at the back of the mountain the average excavation was about 500 cubic yards of place measurement daily, all of which goes out through the west heading to the main crusher plant.

A very important advantage of this method of tunnel driving is that where bad ground is encountered no material delay is experienced. The bottom heading progresses on through the bad material, which is treated carefully at leisure later on. This saves much time in the ultimate completing, and much money and risk in the construction. Some bad ground in break-ups where heavy internal stresses developed in the roof, require considerable timbering. This will be all concreted in with a reinforced single arch before the steam shovel reaches it, so that neither time nor money will have been lost.

In connection with the physical risk involved by this method it is interesting to note that within 15 months since the tunnel headings were started and with nearly a mile and a half of break-ups completed there has been only one fatal tunnel accident.

Bench Excavation.—The side benches, below the level of the jumbo timbers, are taken out, after the break-up excavation has been completed, by a steam shovel operated by compressed air. By this method the benches may be drilled and blasted well in advance and by a special loading device the usual delay in spotting cars is avoided, and no time will be lost by the shovel, making this excavation very cheap and rapid.

At places where a steam shovel cannot be used because of timbering, special construction, or shield work, the benches will be handled by hand and a belt conveyer loading into the tunnel cars.

Shield Work.—At the city end where very soft heavy ground is encountered under most unfavorable conditions, a steel roof shield has been adopted. This avoids settlement of overlying material, reduces the drainage of the surrounding ground, and eliminates the very heavy and expensive timberwork that would otherwise be necessary.

This shield consists of a cutting edge, shaped to conform to the outline of the tunnel roof cross-section, which forms the front of a steel envelope extending over the platforms on which the men work and back far enough to lap over the last "ring" or section of tunnel lining erected. Steel poling boards, semi-attached to the shield will be used, especially in the boulder clay, thus producing a cutting edge that may be advanced in sections where desired.

The shield is supported on steel columns forming the centre wall and on side walls which rest on the solid rock. It is forced ahead by hydraulic jacks, under a pressure of about 5,000 pds. per sq. in. These jacks push against the tunnel lining as it is erected.

The procedure is as follows:—

After a shove, i.e., a move of the shield, 27 in. ahead, a ring of concrete blocks, 27 in. wide, along the axis of the tunnel, by 24 in. thick and about 5 ft. long circumferentially, are set up in place by means of a hydraulic erector. When this tier of blocks is in place, the jacks are put in motion, jamming the new blocks hard against the last tier erected and forcing the shield slowly ahead, as fast as the ground is excavated in front of it. The excavated material, like that in the break-ups, is dropped directly into cars in the heading below. As soon as this shield has made a shove of 27 in. the process is repeated.

Where boulders are encountered the shield will be retarded and the steel poling boards advanced along the rest of the shield face for the 27-in. shove, when the boulder will have been removed in part or wholly.

Where special rectangular sections are built, a steel structure will be erected and steel sheeting used over and around it. This steel sheeting will be advanced by jacks, the structural steel and enclosing concrete being placed under the sheeting as it advances.

By this method the roof is never exposed; the men are never endangered by falling material, and if water is encountered the face can be protected by poling and breast boards with small pneumatic guns, or jacks, so that very little water or ground can escape.

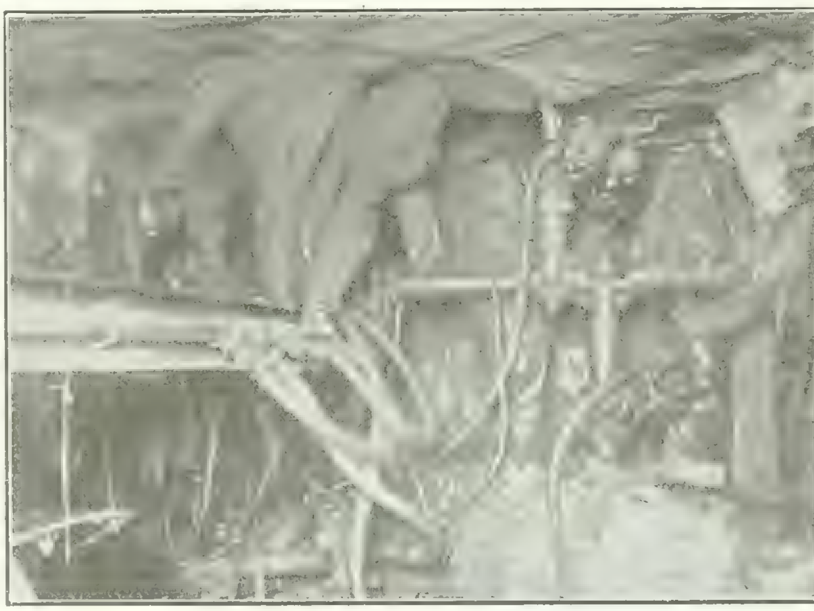

Fig. 3.—Heading Excavation Using Muck Handling Drill Carriage.

The blocks used are very massive and so designed that each block locks firmly into the two adjoining ones of the preceding ring, by oval shaped tenons. They are thus self-supporting and require no forms such as are usually necessary for concrete work. Since they are moulded many weeks in advance, before being brought into the tunnel, when they are erected under the shield they are sufficiently hard to withstand the thrusts of the jacks without injury. The blocks are also so designed that the extrados of the arch is continuous. but the joints in the intrados are about 1¼ inches wide. These joints are held to shape primarily by 3 part wedges or separators and later filled with mortar by means of a cement gun and grouting.

Crusher Plant.—All the rock excavated in the tunnel is being crushed for road materal and concrete stone. All that is not used by the company or railway is sold for local consumption about Montreal. The main crusher plant at the west portal consists of two No. 7 Kennedy gyratory crushers with Stephens-Adamson elevators, con-

veyers and screens. The capacity is about 1,600 cubic yards per day. The tunnel muck is hoisted in cars up an incline to tipples. After dumping, the empties are returned to the tunnel level, through a gravity switchboard. The muck passes through the crushers and is elevated to a revolving screen which separates the stone into the various sizes and distributes it by chutes into bins. It can then be run directly into trucks or cars on tracks connected with both the C.P.R. and G.T.R. The overflow is carried on belt conveyers to various stock piles for the different sizes of stone. From these piles the stone is loaded by means of a locomotive crane and clamshell bucket.

At the city end the tunnell rock is sold as it comes from the tunnel and crushed by an outside company.

The following synopsis gives in a few words the main features of the tunnel itself:—

Length, 3 1/10 miles.

Heading in station site, ⅓ mile.

Grade, 0.6% down towards the city.

Section, 23.5 feet high by 31 feet wide, standard excavation.

Type, twin tube.

Depth, 600 feet below summit.

Geology, Trenton limestone and Essexite with igneous dykes.

Method, bottom centre heading and break-ups.

Progress, best single heading 810 feet in 31 working days, averaging 420 feet per month in each heading.

Gross average, 1,100 feet per month.

An estimate of quantities of material is as follows:—

Excavation, 20,000 cubic yards of earth; 405,000 cubic yards of rock.

Concrete, 50,000 cubic yards.

Steel and iron, 4,400,000 lbs.

Shafts, Maplewood, 240 feet deep; Dorchester, 55 feet deep.

Present pay roll, 1,000 employees.

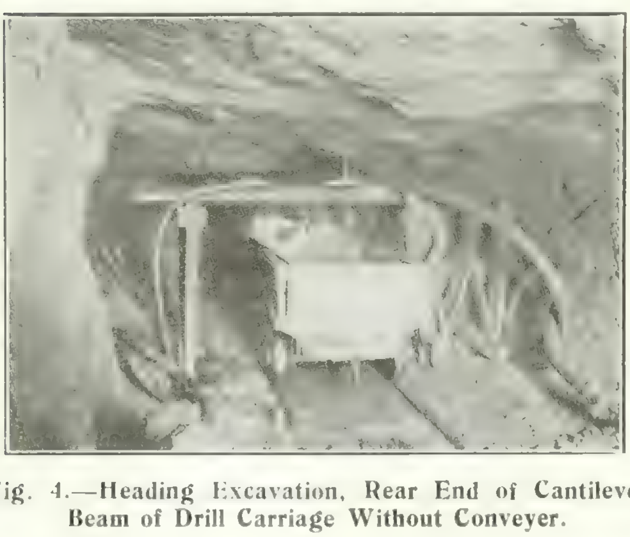

Fig. 4.—Heading Excavation, Rear End of Cantilever Beam of Drill Carriage Without Conveyer.

Present daily consumption of 60% dynamite, 2,000 pounds.

Present daily rate of solid excavation, 900 cubic yards.

Concerning the terminal site, exclusive of buildings, the figures given below are announced in the report:—

Length, 1,200 feet.

Width, 350 feet.

Depth, 50 feet maximum.

Total tracks, 13.

Excavation, 540,000 cubic yards earth; 95,000 cubic yards rock.

Concrete, 100,000 cubic yards retaining walls, track, slabs and platforms,

Reinforcing steel, 3,500,000 lbs.

Structural steel, 8,000,000 lbs.

The Mount Royal Heights station, as designed, gives the following estimate:—

Length, 500 feet.

Depth, 35 feet maximum.

Excavation, 24,000 cubic yards earth; 7,000 cubic yards rock; concrete, 7,000 cubic yards.

Fig. 5.—Break-up Excavation, Showing Bottom Heading With Jumbo Timbers.

Personnel.—The engineering and construction organization is under the direction of Mr. S. P. Brown, B.Sc., Managing Engineer for Mackenzie, Mann & Co., Limited, and Chief Engineer of the Mount Royal Tunnel and Terminal Company, Limited. In the Department of Design, Mr. W. C. Lancaster, E.E., M.E., is electrical and mechanical engineer; and Mr. H. D. Robinson, B.Sc., is engineer of structural design. The Department of Surveys and Alignment is in charge of Mr. Howell T. Fisher, Tunnel Engineer. Assisting him are Mr. J. L. Busfield, B.Sc., on the eastern division, and Mr. R. S. Bassett, B.Sc., on the western division. Mr. J. C. K. Stuart is first assistant engineer, Department of Construction, while Ed. Duffy and Richard Byers are superintendents of the eastern and western divisions respectively.

FINAL WORK ON GATUN DAM.

The two wings of Gatun Dam have been practically finished, the crests being raised three feet above final level, in order to allow for settlement. The remaining work on the dam proper will be in grading the top after the settling. Spoil from the borrow pit beyond the west end of the dam is now being placed at the west end of the east wing, next to the spillway, to cover the draft tubes leading to the hydroelectric station, and to connect the dam by suitable slopes with the side wall of the spillway discharge-channel. The total amount of material placed in the dam to December 1st, 1913, according to the Canal Record for December 24th, was 22,052,666 cubic yards.

Over 1,400 water meters were installed by the city of Regina during 1913.

AMENDMENT TO THE SASKATCHEWAN PUBLIC HEALTH ACT OF INTEREST TO MUNICIPAL AND CONSULTING ENGINEERS IN THE PROVINCE.

AN amendment was passed at the recent session of the Saskatchewan Legislative Assembly, which will prove of interest and advantage to municipalities in that province contemplating the establishment or extension of public health works, and to the engineers acting for such municipalities. The Public Health Act of Saskatchewan is frequently referred to as providing the most advanced legislation in the Dominion with regard to waterworks, sewerage and sewage disposal control.

Previous to the passing of the amendment referred to, the Act required that complete plans and specifications of all waterworks, sewerage or sewage disposal systems or extensions, should be submitted to the Commissioner of Public Health, and his certificate of approval obtained, before any by-law for the purpose of raising money for such works could be submitted to the votes of the electors; and further, that no debentures would be valid if issued under any by-law passed in contravention to the foregoing requirement.

The Commissioner has received the hearty cooperation of the various municipalities in the administration of the Act, but he has noted that in some cases, particularly in the smaller towns, the preparation and submission of complete plans and specifications, previous to the passing of the by-law was a matter which called for re-consideration, because of the following circumstances.

(1) A municipal council taking up office in January required some six weeks in which to formulate the constructional programme for the year. The engineer, on receiving his instructions, proceeded with the preparation of plans and specifications which occupied at least two months. These plans and specifications were submitted to the Commissioner of Public Health during the month of April, and assuming that they were satisfactory to the Commissioner, the by-law could not be voted upon until it had been advertised for three successive weeks. Thus, the electors did not vote until about June 1st, and the necessary procedure following the passing of the by-law, usually delayed the letting of the contracts until the constructional season was far advanced.

(2) Consulting engineers engaged by municipalities had of necessity to incur considerable expenditure in rushing the preparation of detailed plans and specifications, for which remuneration was not forthcoming in many cases until debentures were sold.

(3) There was a possibility of the by-law being opposed by a majority of the ratepayers, in which case, the preparation of the details of the scheme meant unnecessary expense to the municipality.

The difficulties raised will be met by the new amendment, wherein it is required that a report, general plans and such information as may be required to allow of a general understanding of the proposed system or extension may be submitted, and a provisional certificate issued by the Commissioner, which will be sufficient for the purposes of the by-law.

No debentures will, however, be valid until the complete plans and specifications of the system have been submitted and approved.

Regulations will shortly be issued from the Bureau of Health, stating definitely what form the various plans and data necessary for the provisional and final certificates shall take.

SEPARATING WATER FROM CREOSOTE OIL.

By Thomas White,
Assistant Manager of American Creosote Works.

IT is an established fact that it is practically impossible to obtain creosote oil entirely free of water owing to the origin of the oil. After the purchase of almost water-free oil it requires eternal vigilance to keep it so. Some methods of effecting a separation of the water were described by Mr. Thos. White, at the annual convention in New Orleans, of the American Wood Preservers' Association. From his paper the following is reproduced.

Among the conditions which bring about this intrusion of water are difficulties to be expected from the nature of the treating business. Among these are to be mentioned leaks in the steam coils of the storage and treating tanks and cylinders caused by the acids of the oil or the timber, steam condensation and moisture from the timber in the cylinders, or if the plant uses underground tanks seepage of ground water into these through open seams or pin holes. While some water from rainfall becomes mixed with the oil if in open tanks, this can be siphoned off directly from the top. This free water is really an asset in that it affords positive fire and lightning protection.

In these varous ways water is slowly accumulated in the oil. This water is readily gotten rid of by the use of the steam coils in the tanks which are brought into every-day use, but if kept cold in a reserve storage tank which is only drawn on at wide intervals we may expect some difficulty from it. In this cold condition the contents will stratify in the tank into three main horizontal zones, each of varying depth, depending upon the gravity of the oil. The top zone will be free water floating over the middle one, which is an emulsion, while the bottom zone will contain the least amount of water, which we incorrectly say is in chemical combination with the oil. The water in this bottom zone is usually such a small portion, within our lawful allowance, that it will hardly be troublesome This zone is the most accessible in the tank, and very likely will be first used. It is the water in the middle zone which is most difficult to eliminate. Heating the contents to boiling point in an open tank with steam coils will create an upward circulation, which will continue after the steam has been shut off and until the liquid thoroughly cools. Since the water is lighest it will rise to the top, where it can be readily drawn off. If the tank is provided with an agitator it will greatly facilitate the operation, causing quicker evaporation and stratification.

The other method of water extraction, which is the best but not always justifiable at the creosoting plant, is the still method. Ordinarily, the use of the still for this purpose at the treating plant is so seldom required, coupled with its comparatively higher cost of installation and maintenance, make it rather prohibitive there. Although the still may be used to refractionate the oil to make either a lighter or heavier one, at the same time the open tank, with its necessary steam coils, is always reserve storage capacity.

Of the two styles of stills, namely, the horizontal and the vertical, the latter is thought by the writer to

be the more preferable for water removal, although the horizontal still seems to be used almost universally throughout the United States for tar distillation. Even from the point of construction and maintenance the vertical one is most favorable in that it would not require a separately built smokestack and when burned out at the bottom could be replaced easily. It should induce better evaporation in that there would be a more direct and quicker circulation of the gases. While the heating surface appears less this may be increased by the use of vertical fire flues, which would also serve as smokestacks. There would also be less tendency to foam, which means that the operation could be rushed more with less danger of the oil boiling out of the still.

The open-tank method described above should evaporate at least 1 per cent. of water per day while the liquid is kept heated above 180° F., not to mention the free water which would separate and rise to the top. The still method would probably evaporate about 1 per cent. of water per hour. The still would require extra fuel and attention, whereas the open-tank coils would tax the main boiler and its fireman very little more.

Of course, there are numerous other methods of water extraction, such as the centrifugal and vacuum processes, some of which might be preferred in individual cases.

THE WORKING OF GYPSUM.

Mr. L. C. Snider has published some good information in Bulletin 11 of the Oklahoma Geological Survey, concerning the calcining of gypsum.

Its principal commercial value arises from the fact that at the moderate temperature of 130° C., three-fourths of its water of crystallization is expelled, yielding plaster of paris. Water begins to come off below 100° C., but very slowly up to 130°. At 163° C. more water is expelled, and if a temperature of 221° is not exceeded, the resulting plaster is still serviceable, but if calcined above that temperature, the plaster becomes increasingly slow to set with the addition of water. At 343° C. gypsum is completely dehydrated, and the "dead burned" plaster loses all hydraulic properties, becoming $CaSO_4$, or anhydrite.

In practice, two dissimilar methods are employed for calcining gypsum. The older method uses kettles holding up to 25 tons. The gypsum is first pulverized by passing successively through jaw crushers, gyratory crushers, and buhr mills, and is then charged slowly into the kettles, which are heated from outside and are provided with interior stirring devices. In about 1 hr. after filling, the mass reaches a temperature of 230° F. and begins to "boil" by raped expulsion of water. When it reaches 350° F., the plaster is discharged into a cooling pit, and is afterwards screened, the coarser grains being reground.

The more modern Cummer continuous process utilizes a rotary kiln through which furnace gases and hot air are drawn by fan. In this method, the gypsum is crushed only to nut size before being fed automatically and continuously into the kiln. It passes through the kiln in about 10 min. and is discharged at a temperature of nearly 500° F., which, however, is not sufficient to "dead burn" the gypsum, owing to the presence of moisture which is not fully expelled during the short stay in the kiln. The hot gypsum is then stored in brick bins, where the mass acquires a uniform temperature just sufficient to produce plaster paris of the right quality. The calcined lumps are then pulverized and sifted. The advantages of the latter method are (1) that less than half so much fuel is required per ton of output, owing to the continuity of the heating, and (2) less power is required to pulverize calcined than raw gypsum.

COAST TO COAST.

St. Mary's Ont.—A new C.P.R. station at St. Mary's has been opened recently for public use.

St. Thomas, Ont.—Water has been pumped into the new water tower at St. Thomas, and no fault has been found in the construction.

Edmonton, Alta.—Estimates amounting to $1,325,161 as expenditure for maintenance and operation of the city utilities department are being considered by the Edmonton City Council.

Port Nelson, Ont.—The last mail received from Port Nelson, which arrived at Ottawa, contained the information that the tower of the wireless station being constructed there to connect with Le Pas, had attained the height of 150 feet on December 15th. It is estimated that, by this time, it is complete.

Guelph, Ont.—The annual report of the road superintendent submitted last week at the county council showed the amount expended under the Highway Improvement Act last year to be $61,283.95. Of this sum, $25,968.97 was expended upon bridges, and $35,314.98, upon culverts and general road construction .

Ottawa, Ont.—The annual report of the N.T.R. Commission for the financial year ending March 31, 1913, showed the total expenditure for construction as $13,729,461; or, the total expenditure from March, 1904, to March, 1913, as $130,-247,152. The total grading done by March, 1913, was 1,739 miles. The total miles of track laid was 1,720 miles on the main line and 384 miles on sidings and double track, making a maximum total of 2,125 miles.

Winnipeg, Man.—The surplus on the operation of Government telephones for the year ending November 20, is shown by the report of the Hon. Hugh Armstrong, provincial treasurer, to be $30,264.64. The total revenue for the year is quoted as $1,707,149.74; net earnings, $437,239.84; and interest charges, $406,975.20. The report also details large expenditure on new construction during the year, as well as a general increase in the salaries of employees throughout the system.

Verdun, Que.—Some months ago, Verdun embarked upon a project to prevent just such an emergency as occurred recently in Montreal—i.e., it reorganized its water service, the result being that within a few weeks, it will have in operation a new pumping plant capable of supplying to the town 4,000,000 gallons daily, this in addition to two reserve pumps, which at present supply 3,000,000 gallons daily, making a total of 7,000,000 gallons; while the total consumption of the town at present is only 1,000,000. The new pump is supplied by a separate intake, the two already in existence supplying the two reserve pumps, and will provide, when it is completed, three distinct and complete sources of water supply. In addition, the water will be filtered.

Fort William, Ont.—A busy season in ship repair and construction is reported at the harbor of Fort William, and also at the Port Arthur drydocks. At Fort William, the tugs "Sarnia" and "Home Rule," owned by the Thunder Bay Contracting Company, are undergoing extensive alterations and repairs; and the eight dredges which have been working in the harbor during the past season for navigation, are being overhauled in preparation for next season's work. At Port Arthur, the work on the large steel freighter under construction is progressing favorably and it is expected that the vessel will be launched about the end of March. Also new motors have been installed in the C.P.R. steamers "Alberta" and "Athabasca"; new pistons are being installed in the engines; the wiring system of the boats is being entirely renewed; new anchors have replaced the old-fashioned ones; and alter-

ations to the cabins have been commenced. Repairs have also been completed to the "Plummer," "Dwyer" and the tug "James Whalen."

Regina, Sask.—Considerable interest is manifested in Regina in the natural gas proposition made by the Coste-McAuley Syndicate, which has been favored by the city council. According to the terms of this agreement, the city will secure natural gas at the rate of 20 cents per cubic foot, which will mean that power can be supplied to industrial concerns at a nominal figure without incurring any loss to the city. The power problem has been recognized by the city for some years past as a difficult one; and, although Regina's rates were lower than those of practically every city in the west, it was recognized that the advantage to industrial concerns was to a certain extent off-set by the high rate for power. With natural gas at this price, it is claimed that power rates for such as milling enterprises, etc., would be reduced to a minimum; and all of Regina's business men are very optimistic with regard to the probability of greater industrial development. The gas will be secured within 100 miles of Regina, and piped to the city.

Montreal, Que.—This city is now advertising for tenders for the fourth unit of work in connection with the filtration plant under construction. This last portion requires an approximate expenditure of $150,000, which will bring the total cost of the plant to about $1,350,000. The construction of the filtration plant was divided into four portions—namely, the supply and installation of the machinery; the construction of final filters, including gravel and sand beds; the construction of pre-filters and filtered water reservoir, and the construction of buildings. The first three contracts are not quite completed, much delay having been experienced in the laying of the foundations, which were damaged by frost in the course of last winter and had to be repaired. The British Electric Plant Company, of Alloa, Scotland, for the sum of $40,250, is supplying and installing the pumping machinery, which consists of 14 centrifugal pumps directly connected to the electric motors, 4 of which are of a capacity of 17,500 gallons per minute, 2 of 11,600, 2 of 5,800, 2 of 1,300, 2 of 330 and 2 of 150 gallons. The rotary blower to be connected to an electric motor has a capacity of 5,000 cubic feet of air against 5 pounds per square inch pressure. The contract also provides for the supply of 2 hand-operated cranes of a capacity of 6 tons. Mr. Norman M. McLeod is executing the contract for the second division of the work at a cost of $673,000, and also for the third division at a cost of $485,000. This third contract calls for 16 reinforced concrete pre-filters of the mechanical type of 3¼ million gallons each per 24 hours; and for a reservoir with a capacity of 6¼ million gallons.

Victoria, B.C.—Arrangements are being made for an early start this year on the water rights investigation work being carried on in Greater Vancouver and in the lower Fraser Valley. That portion of the work of particular interest to Greater Vancouver is the measurement of the flow in Lynn, Seymour, and Capilano Creeks and their tributaries; and calculations as to water storage possibilities on these streams and investigation into the watershed situation with a view to ascertaining what damage might be done to the water supply by the removal of the timber on alienated land. Much of this work has been under the direction of Surveyor W. C. Smith; and he will continue his field investigations during the coming season. The work in the entire district mentioned is under the control of E. A. Jamieson, one of the assistant engineers of the provincial water rights department. The work on the north shore will be under the immediate supervision of William Young, comptroller of the provincial water rights branch. The investigations of the water rights department will have the effect of putting Vancouver's claim in Seymour Creek on a more definite basis. It has been reckoned that there are 3,000 miners' inches of water in the creek, of which 1,700 are controlled by the city of Vancouver, including those acquired from Point Grey and Burnaby for conveying water to those municipalities. The volume of water has never been known with any certainty, and doubt has been expressed that there are 3,000 miners' inches in the dry season. Moreover, the surveys of the Seymour Creek watershed by the department of water rights will have direct bearing on the scheme for conserving the water supply being put forward by Vancouver. On the report of this department, and of the forestry branch which has been investigating the timber in the watershed, will depend whether or not the city will buy the timber rights and crown grants above Seymour Falls for a reservoir.

Vancouver, B.C.—It seems a certain thing that by early March the eastern portion of the new C.P.R. station at Vancouver will be occupied. When the office staff and regular facilities have been transferred to this new structure, the work of razing the old depot will be undertaken, and upon its site will be constructed the Granville viaduct, which is another of the terminal units planned by this railway system. The new station will measure across the tracks from east to west, 480 feet, or practically two blocks long. It is being constructed of red brick, terra cotta, and granite and limestone trimmings. Along the Cordova street side there will be ten great Corinthian free-standing columns and ten engaged columns, constructed of limestone. The great entrance will open out directly on Cordova Street. From this entrance straight through the general waiting-room will be the main entrance and exit to all trains. There also will be an entrance off Granville Street and one on the track side for third-class passengers from the wharves and trains. In all, there will be six entrances. There will be two floors below the street level on the track side. Baggage and express departments will occupy most of the room in these. Here also will be the mail room, telephone exchange, service department, pump and boiler-rooms, also two large electrical transformers for lighting the building and running the elevators. The lower mezzanine floor is to be occupied by the kitchen; the central portion of the main floor by the general waiting-room, which will be 150 ft. long and 60 ft. wide, with massive pillars at the sides and a ceiling heavily beamed and panelled, 40 feet above the floor. In this room the lunch counter will be installed. A large lobby will open from the main waiting-room for first and second-class passenger business, while the third-class waiting-room and ticket office will be on the upper mezzanine floor. On the main will be located also the general freight department, general passenger agents, baggage agents, claims agents, as well as the offices of the Canadian-Australian steamship service, commissary, etc. Finally, the attic floor will be occupied by the general staff and all offices, such as private bureaux, the draughting-room for the engineering department, the railway telegraph and the like.

PERSONAL.

CHAS. H. KEEFER, C.E., Ottawa, was elected to the Board of Directors of the American Society of Civil Engineers, at its annual meeting in January.

W. G. CHACE, Chief Engineer of the Greater Winnipeg Water District will address a meeting of the University of Manitoba Engineering Society, on February 9th.

S. G. PORTER, M.Am.Soc.C.E., addressed the Calgary branch of the Canadian Society of Civil Engineers at a meeting on January 23rd, on "The Engineer and his Relation to Society."

P. B. McGINNIS, until recently connected with the Canada Cement Company, in their Winnipeg office, has been

transferred to Medicine Hat to take charge of the construction work of the company's plant, No. 14, there.

A. N. PITCHER, who has been constructing engineer during the development period of the Canadian Coal and Coke Company in Alberta, has been appointed chief engineer. The head offices of the company are at present in Montreal, but they will be moved to the collieries near Lethbridge.

FRANCIS P. SMITH, M.Am.Soc.C.E., chemical and consulting paving engineer, New York City, on January 29th, delivered before the graduate students in Highway Engineering at Columbia University, an illustrated lecture on "Plant, Highway and Laboratory Inspection of Bituminous Materials."

GEO. JANIN, City Engineer of Montreal, has been seriously ill for several weeks and shows little improvement. The Board of Control has relieved him of all responsible duties for a month. During the repair of the conduit break a month ago, Mr. Janin remained continuously in charge, and his physicians now attribute his present illness to overexposure.

ARTHUR H. BLANCHARD, M.Am.Soc.C.E., Professor in Charge of the graduate course in Highway Engineering at Columbia University, on January 26, 1914, delivered illustrated lectures at the University of Illinois on the subjects:—"Bituminous Surfaces and Bituminous Pavements" and "Modern Developments in Highway Engineering in Europe."

DOUGLAS C. LIVINGSTON, B.Sc., a graduate in mining of McGill University, and for some years prominently connected with mining operations on Vancouver Island, has been appointed head of the mining engineering department of the University of Idaho. For the past three years he has been associate professor of mining. He succeeds Prof. R. S. McCaffery, who lately resigned to join the faculty of the University of Wisconsin.

H. N. RUTTAN, City Engineer of Winnipeg, addressed the University of Manitoba Engineering Society recently on "Advice to Young Engineers." Col. Ruttan dwelt first on the necessity for carefulness, accuracy and attention to detail, realizing from the first the sense of responsibility in all matters. He impressed the importance of loyalty, particularly to the chief of the staff. No engineering achievement is a one-man proposition, it requires the united efforts of the whole staff to bring it to a successful conclusion. The exercise of the faculties of observation to the fullest extent in connection with any project is necessary, and notes on all matters in relation to it are of great importance. The young engineer should not be content but should qualify for higher responsibilities. He must be well informed on all public matters of engineering interest, and be able to clearly present his views.

Recent appointments to positions in the Topographical Surveys Branch, Department of the Interior, Ottawa, include those of L. T. Venney, Brockville, Ont.; W. K. Thompson, Toronto; Alan Fraser, Toronto; L. S. Cockburn, Toronto; C. M. O'Neill, Erindale, Ont.; A. L. Morgan, Kingston; W. E. Lumb, Fort Stewart, Ont.; W. W. Doxsee, Peterborough, Ont.; H. J. Dunlap, Ottawa; and Jas. Hall, Edinburgh, Scotland. The first five mentioned are graduates in engineering of the University of Toronto.

OBITUARY.

THOS. M. McLEOD, C.E., of the firm of McLeod and Merrill, Toronto, and a graduate of McGill University, died recently of appendicitis. Mr. McLeod was a native of Georgetown, P.E.I. He had been connected with many extensive engineering contracts in Canada and the United States.

MANITOBA LAND SURVEYORS.

The thirty-fourth annual meeting of the Association of Manitoba Land Surveyors was held in the Industrial Bureau Buildings, Winnipeg, on January 21 and 22. After a very interesting address from the retiring president, J. L. Doupe, chief surveyor of the Canadian Pacific Railway Company, the following papers were read and discussed:—

"Early Surveys and Land Administration in Manitoba," by William Pearce, of Calgary.

"How to Treat the Closing Error," by C. C. Chataway, of Winnipeg.

"Accuracy in Field Work," by A. C. Garner, chief surveyor of the land titles office, Regina.

"Special Surveys," by G. B. McColl, of Winnipeg.

"Right of Way Surveys," by F. A. Wilkin, Winnipeg, right-of-way surveyor for the Canadian Pacific Railway Company.

"Street Plans and their Control," by H. F. McDonald, of Winnipeg.

"Some Useful Diagrams in Computing Earthworks," by H. L. Vercoe, Winnipeg.

The following officers were elected for 1914:—C. C. Chataway, president; R. J. Jephson, vice-president; W. B. Young, secretary-treasurer; and G. A. Bayne, H. F. McDonald, R. C. McPhillips and R. H. Avent, as members of the executive council; and H. G. Beresford and H. A. Bayne, as auditors.

"THE ELECTRIFICATION OF STEAM RAILWAYS."

This was the subject of an illustrated address by Mr. N. W. Storer, of the Westinghouse Electric and Manufacturing Company, Pittsburg, delivered to the Toronto section of the American Institute of Electrical Engineers on January 30th.

LECTURE ON STEEL TUBE MANUFACTURE.

The University of Toronto Engineering Society will hold a special meeting in Convocation Hall this evening (February 5th), at 8 p.m., which will be addressed by Mr. F. N. Speller, B.A.Sc., a graduate in engineering of the University of Toronto. Mr. Speller is Metallurgical Engineer for the National Tube Company, Pittsburg, Pa., and will give a lecture on the manufacture of steel pipes and tubes. His talk will be illustrated by motion pictures showing the methods of manufacture. The Canadian Railway and Engineering Club will attend the meeting in a body.

COMING MEETINGS.

WESTERN ONTARIO CLAY PRODUCTS ASSOCIATION.—Convention to be held in Chatham, Ont., February 4 and 5, 1914.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

NATIONAL CONFERENCE ON CONCRETE ROAD BUILDING.—Meeting will be held in Chicago, Ill., February 12th to 14th, 1914. Secretary, J. P. Beck, 72 W. Adams Street, Chicago, Ill.

AMERICAN WATER WORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Deven, 47 Slate Street, Troy, N.Y.

WATER POWERS ON THE WINNIPEG RIVER

FROM A REPORT TO HIS HONOR, JUDGE H. A. ROBSON, PUBLIC UTILITIES COMMISSION, WINNIPEG, PREPARED BY THE WATER POWER BRANCH, DEPARTMENT OF THE INTERIOR; J. B. CHALLIES, B.A Sc., SUPERINTENDENT. J. T. JOHNSTON, HYDRAULIC ENGINEER

IT has long been recognized that there is an enormous reserve of potential water power on the Winnipeg River within the province of Manitoba. The rapidity with which the existing developments on the river have been, and are being increased to their capacity, and the active interest that has been taken in the undeveloped power sites of the river, have compelled the Dominion Government to give the water power resources on this river careful and full consideration. Within the last few years there have been presented to the Dominion Government many applications for power privileges on this river; schemes have been proposed for the utilization of various portions of the natural fall, some contemplating the combination of several falls by the concentration of their respective drops at one power site, and others simply proposing the utilization of the drop at a particular fall. These have been so varied and so conflicting, and at the same time supported by such reputable engineering advice, that the government found it inadvisable to commit itself with respect to any further developments on the river until it had first caused to be made a complete survey and investigation of the whole river, with a view to securing such information as would enable the dictation of developments which would con-

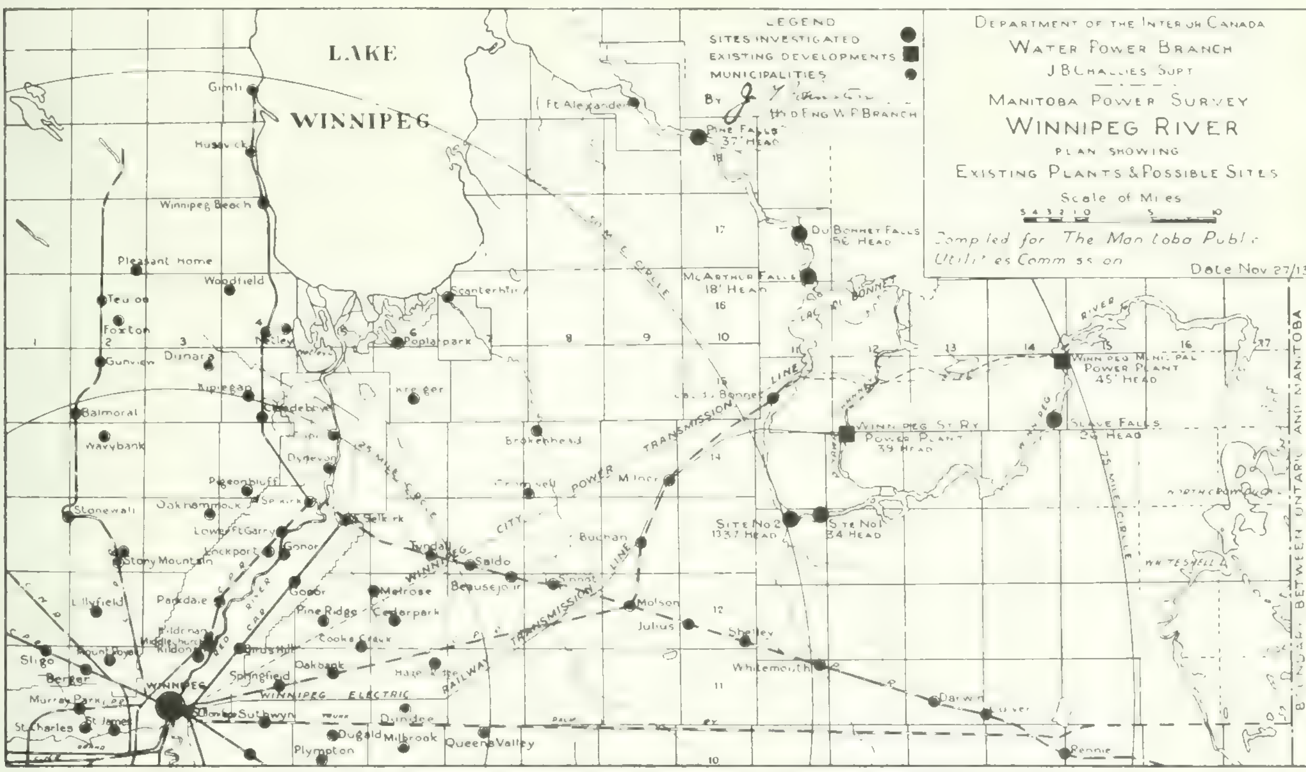

Fig. 1.—Existing Plants and Possible Sights Around Winnipeg.

template the maximum possible advantageous utilization of the water power resources of the river. These investigations were started early in the year 1911, under the consulting advice of Mr. J. B. McRae, C.E., of Ottawa, and the field work has proceeded vigorously to completion under charge of Mr. D. L. McLean. For the purpose of this report for the Public Utilities Commission, which had to be completed by December 15th, 1913, plans based on this field work have been rushed to completion, and a preliminary provisional estimate made by the engineers of the Water Power Branch, of the best method of concentrating the various separate falls of the river to enable all the natural fall to be utilized for power purposes, and at the same time have each unit develop-

ment a component part of the comprehensive scheme for the whole river. These concentrations are indicated in plan and profile on Figs. 1 and 2. A study of this profile will illustrate the completeness with which the objects on the continent; it flows in a westerly direction connecting the Lake of the Woods with Lake Winnipeg. The basin drained comprises an immense area of some 55,000 sq. mi., lying at the westerly end of the Lauren-

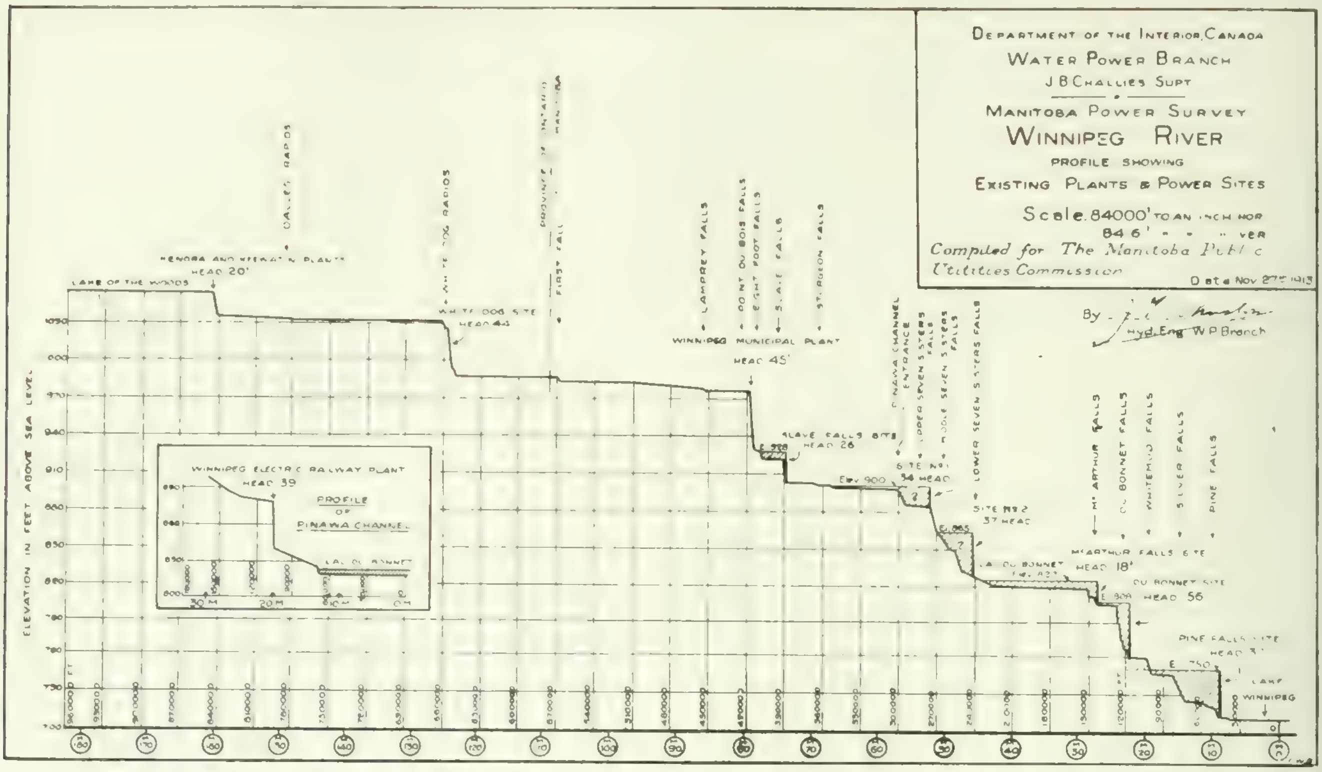

Fig. 2.—Profile, Winnipeg River Survey, Showing Existing Developments and Power Sites.

of the investigation have been realized, and the full conservation of the power resources of the river provided for.

Description of River and Drainage Basin.—The Winnipeg River is one of the most notable power rivers tian Plateau. As is typical of Laurentian country, the area is dotted with innumerable muskegs and lakes, the latter varying in size from small ponds to the Lake of the Woods with its area of 1,500 sq. mi. Certain gen-

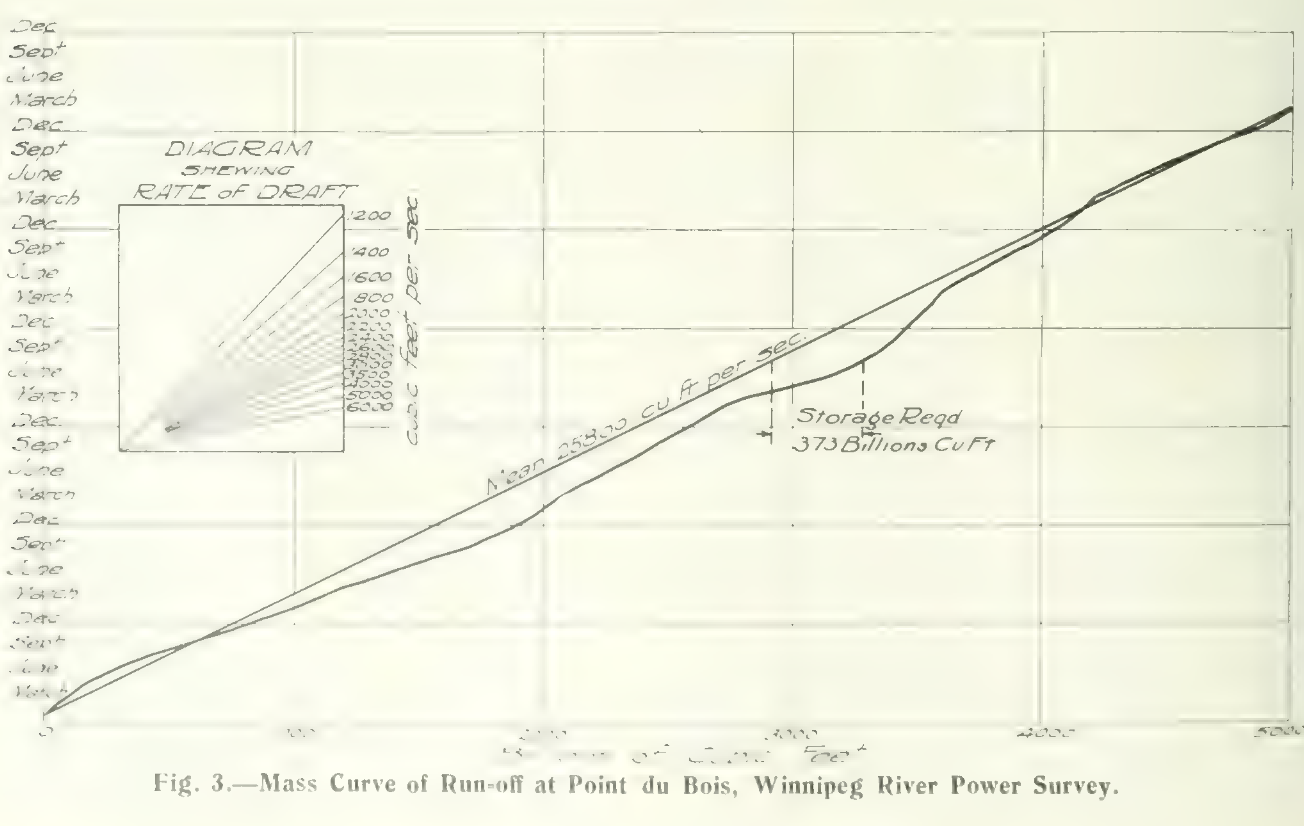

Fig. 3.—Mass Curve of Run-off at Point du Bois, Winnipeg River Power Survey.

eral characteristics apply to the drainage basin as a whole, since practically the entire area is of Laurentian formation with an overlying soil of glacial origin. The country is rough and hilly with large areas of rock outcrop. This latter feature applies in the main throughout the Winnipeg River, and lends itself to a characteristic formation throughout the river channel, which is of exceptional value in the interests of power development. The larger proportion of the river bed in the province of Manitoba, consists of a series of deep cup-like basins, forming small lake-like expanses with little or no current. The river flow finds its way from these basins by falls and rapids over the rock formation which is always in evidence at the outlets, and which forms at once the means of egress from, and the controlling feature of, the basin water level. These falls form the natural power sites along the river.

and finally discharging into Rainy Lake. These upper waters in the main constitute a portion of the International Boundary. Many streams heading in upper lakes and muskegs also contribute to the flow from Rainy Lake. This latter has a surface of 330 sq. mi., and a drainage area of some 14,600 sq. mi. Rainy River, which is the outlet, discharges into the Lake of the Woods. From this latter lake to Lake Winnipeg, the river is known as the Winnipeg. Forty miles down the river from the Lake of the Woods, the flow of the English River enters that of the Winnipeg. This tributary is of almost as large dimensions as the river into which it flows, as it drains an area of 22,000 sq. mi., while the Winnipeg at the Lake of the Woods outlets, has a drainage area of 25,000 sq. mi. From the Lake of the Woods to Lake Winnipeg, there is a total drop of 341 ft., and of this a 70-ft. drop takes place above and a 271-ft. drop

Ottawa Ont. Dec. 12 1913

Fig. 4.

A valuable timber growth including spruce, tamarack, birch and pine, occurs throughout the whole district. Lumbering is carried on extensively, and in addition, pulp and paper industries have been established at Fort Frances and Dryden. Notwithstanding the great extent of rock outcrop, considerable area is available for farming, this applying more especially to the Whitemouth and Rainy River districts. While there are several prosperous towns such as Fort Frances, Rainy River and Kenora in the basin, yet the greater portion of the country has not been settled and is still in the state of nature.

The upper watershed reaches to the height of land separating the Atlantic drainage from that of Hudson Bay into which the waters of the Winnipeg River eventually flow. North Lake, which is situated on the International Boundary, some 45 miles west of Lake Superior, is the headwater of the drainage basin. From North Lake the stream flows westward, passing through many small lakes, collecting the flow of numerous tributaries

below the junction with the English River. As this junction occurs practically at the boundary between Ontario and Manitoba, it follows that the combined flow of the two rivers and the greater drop as noted above are available for power purposes in Manitoba. Of this head a considerable portion is already being utilized by existing developments on the river.

Flow Records.—Estimates of the daily flow of the Winnipeg River have been compiled by the Manitoba Hydrographic Survey, based on discharge measurements secured by them, together with results of measurements supplied by Col. Ruttan, D. A. Ross, and the City of Winnipeg power engineers. These estimated discharges are referred to the flow of the river at Point du Bois and extend over a period of six years. For this period a maximum flow of 53,400 sec.-ft. and a minimum flow of 11,700 sec.-ft. have been recorded. The high-water marks along the shore would indicate that floods of 100,000 sec.-ft. have occurred in the past. Such floods must, however, take place at rare intervals.

Storage on the Upper Waters.—The question of storage on the upper waters of the Winnipeg River is at present somewhat involved, in that the regulation of the Lake of the Woods has become an international question and is now before the International Joint Commission. Considering that the lake has a tributary drainage area of 25,000 sq. mi., and a surface area of 1,500 sq. mi., offering unexcelled storage facilities, it is of vital importance to the powers of the Winnipeg River, that storage should be had on this lake. Partial regulation of the drainage tributary to Rainy Lake is now controlled on Rainy Lake by the dam of the Ontario and Minnesota Power Company at Fort Frances.

Second of the Seven Sisters Falls Sites, Winnipeg River.

By the establishment of storage reservoirs on the English River, the flow of the latter can be regulated; and in conjunction with storage on the Lake of the Woods drainage basin, practically a complete regulation of the flow of the Winnipeg River in Manitoba can be attained.

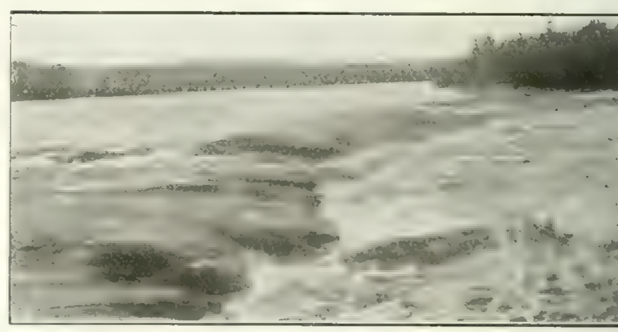
During the period of the last six years, over which records of the flow of the Winnipeg River extend, a minimum flow of 11,700 sec.-ft. has been recorded, as stated above, while the maximum flow in the same period is 53,400 sec.-ft., a range of only 1 to 4, which is illustrative of the extremely low fluctuation under practically natural conditions. Yet, by an adequate system of storage this flow can be so regulated that the minimum flow will be increased from about 12,000 sec.-ft. to some 20,000 sec.-ft. In Fig. 3 is shown a mass curve of the flow of the river at Point du Bois for the period from January 23rd, 1906, to December 31st, 1912. For this period a storage of 373 billion cu. ft. would have been necessary for a complete regulation.

Existing Power Plants.—(a) Winnipeg Electric Railway Co.—The Winnipeg Electric Railway Company's development is situated some sixty miles from Winnipeg on the Pinawa or Lee Channel. This channel was not the main river bed, but was an old high-water channel, of some 25 miles length which has been improved and is being further enlarged. The water for the plant is turned into the Pinawa Channel by three diversion dams, the main of which consists of 1,332 ft. of concrete capped rock fill across the main channel, connected with the banks on either side by concrete spillways bringing the total length to 1,650 feet. Two small weirs of timber crib type span secondary channels. The water thus diverted flows down the improved canal to a central dam which is capable of shutting off the flow and returning a portion or all of it to the main river over the waste or diversion weir. From this point the water flows through the tortuous bed of the old high-water channel, the same having been deepened and partially strengthened by excavation. This waterway, while at present capable of carrying in summer some 10,000 sec.-ft., is only able in winter, on account of the ice, to deliver about two-thirds of this amount. Below the power house the tail-race has been improved by much dredging and excavation. The power house is situated at a bend in the river where a concrete dam with arched spillway creates a thirty-nine-foot head. These headworks are equipped with debris boom, ice-run, spillway, trash-ranks and head gates. The electrical units of this plant consist of five 1,000-kw. and four 2,000-kw. revolving field, 60-cycle, two 300-volt, 3-phase generators, together with two 125-kw., 125-volt d.c. exciters. The generators are capable of carrying a 50% overload, giving in all a total output of 19,500 kw. or 26,140 h.p. While 19,500 kw. are available at this plant for peak loads, an additional 9,000 can be obtained from an auxiliary steam turbine station at Winnipeg operated by the company. The electric energy is transmitted to the City of Winnipeg at 60,000 volts over a 65-mi. transmission line.

(b) City of Winnipeg Municipal Plant.—The muninipal power development of the City of Winnipeg is situated some 77 mi. northeast from Winnipeg at Point du Bois on the Winnipeg River. This plant consists essentially of a large concrete power station, with retaining walls and spillways, forming the forebay, the entrance to which is controlled by a stop-log sluiceway type of headgate. Two concrete weirs or spill dams control the elevation of the headwaters, and together with a rock-fill dam divert the water to the forebay for use at the power house.

This power concentration has created a head varying from 44 to 48 ft., with a pondage of 7 sq. mi. above the plant. This pondage is a great asset during periods of peak loads.

The development is designed for an ultimate installation of 16 units, each consisting of two-runner high specific speed turbines rated at 5,200 h.p. for 46-ft. head and a 3-phase 3,000-kw. generator. The first installation would give 48,000 kw., with turbines of a maximum capacity of 83,200 h.p. As each turbine unit requires 1,250 sec.-ft. under maximum output at a net head of 45 ft. and running at 164 r.p.m., the total water required would be 20,000 sec.-ft., plus the water for the two small extra units.



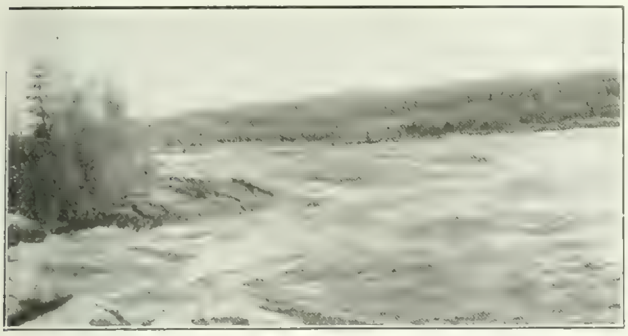
Main Drop of Second McArthur Falls, Winnipeg River.

The present installation consists of 5 generators of 3,000 kw. each and two exciters of 250 kw. each, making a total of 15,500 kw., and at maximum load requires 7,800 sec.-ft.

The electric energy is transmitted to the City of Winnipeg at 66,000 volts over a 77-mile transmission line, built on a municipally owned 100-ft. right-of way.

The conductors are of aluminum, supported on steel towers throughout. A duplicate line is now under consideration.

Basis of Discussion on Government Power Proposals.—The cost estimate for the government power proposals on the Winnipeg River refer in all cases to the capital cost of installation and are based on both an initial and final development. The initial development is designed to utilize at each site the present minimum flow of the river, i.e., 12,000 sec.-ft., or such portion of it as may be available at the particular site in question. The final development is designed to utilize at each site,



Main Drop of Pine Falls, Winnipeg River.

a regulated flow of 20,000 sec.-ft., or such portion of it as may be available at the site. After the diversion of sufficient water in the Pinawa Channel to operate the plant of the Winnipeg Electric Railway Company under normal peak load conditions, there would remain for use at Seven Sisters in the main river about 4,000 and 12,000 sec.-ft. under unregulated and regulated conditions of the river respectively. It is important to note that it is on this basis that the available power at the Seven Sisters sites is discussed.

In order that the power sites could be compared on a rational and equitable basis, all the layouts and designs have been standardized in so far as possible, giving full consideration to the varying heads, and to the local physical conditions at each individual site. No allowance has been made in the estimate for transmission, the costs being in all cases the capital cost for power on the switchboard in the power house, and the power being considered as straight 24-hour power at 75% efficiency, based on the flow. This forms a very conservative basis. Transmission costs are omitted from the estimates as it is impossible to foretell the use to which the power at the various sites may be applied when developed, and a straight comparison of the sites as they stand is desired. The costs given herewith may be slightly altered upon final revision.

In all cases the dams are designed in solid concrete, with ample discharging capacity to pass the severest floods to be anticipated. The power stations have been developed on single-runner vertical turbine installations, varied for the different heads and to meet local conditions.

A continuous profile of the river to sea level datum was run at the beginning of the field work, and forms the groundwork upon which the whole survey was developed. Recognition of the future needs of navigation has been given and provision in the permanent work for the accommodation, if necessary, of future lockage facilities at the different sites has been made.

Government Power Proposals.—(a) Slave Falls Site.—The proposed development at Slave Falls concentrates a head of 26 ft. formed by the combination of the Slave and Eight Foot Falls. The dam runs along the crest of the falls and curving downstream through an arc of about 90°, connects with the power station on the right bank of the river. Provision has been made for the future installation of a lock on the left bank.

The head and tail water elevations as at present proposed, are 928 and 902 respectively. The initial installation on which the estimate is made provides for eight 5,000-h.p. turbines, sufficient to provide for a flow of 12,000 sec.-ft. at 8/10 gate, with a spare machine for emergencies. On a 75% efficiency, 24-hour basis, 26,600 h.p. will be available at a capital cost of $93.45 per h.p. at the switchboard. The final installation provides thirteen 5,000-h.p. turbines, sufficient for a flow of 20,000 sec.-ft. at 8/10 gate with a spare machine. On a 75% efficiency, 24-hour basis, 44,400 h.p. will be available at a cost of $83.30 per h.p. at the switchboard.

(b) Seven Sisters Sites.—No detail work has as yet been possible covering the best method of development of this reach of the river. However, it is considered that it can ultimately be developed at two sites of about 34 and 37 ft. head respectively. After providing sufficient water for the plant of the Winnipeg Electric Railway Company on the Pinawa Channel, it is doubtful whether any development of the Seven Sisters Falls will be feasible until the flow of the river can be regulated to at least 20,000 sec.-ft., by means of storage in the upper waters. The power available at the 34-ft. site, under unregulated conditions, is about 11,600 h.p. and under regulated conditions, 34,800 h.p. Similarly the 37-ft. site will render available 12,600 h.p. and 30,700 h.p. respectively.

(c) McArthur Site.—At the lower of the two McArthur Falls, a head of 18 ft. awaits development. The river is here divided into two channels by a large island. The

Silver Falls, Winnipeg River.

general layout consists of a solid concrete spillway along the crest of the fall on the right or main channel, and a long spillway and embankment, including sluiceway provision, running diagonally across the island, and connecting with the power station spanning the left channel. Provision is made on the island for the future construction of a lock.

The head water elevation is at present fixed at 827, i.e., about one foot above the recorded highest water level of Lac du Bonnet. The tail-water is proposed at 809, giving a head of 18 ft.

The initial installation provides for eleven 2,500-h.p. turbines, sufficient to provide for 12,000 sec.-ft. at 8/10 gate, with a spare machine for emergency. On a 75% efficiency, 24-hr. basis, 18,400 h.p. will be available at a capital cost of $123 per h.p. at the switchboard. The

final installation provides for seventeen 2,500-h.p. units on a basis of a 20,000 sec.-ft. flow, and 75% efficiency, 24-hr. power, i.e., of 30,700 h.p. The cost per h.p. on the switchboard is $97.50. This site can be given a much more favorable aspect, when the local storage available in Lac du Bonnet (whose 32 square miles form the head-waters) is taken into consideration.

(d) Du Bonnet Site.—The proposed scheme of development at the Du Bonnet Falls will ultimately concentrate there a head of 56 ft., made up of the Grand and Little du Bonnet Falls, and the Whitemud Falls. The latter will be added by blasting out the rock bridge over which the present fall takes place. The dam, consisting of embankment, spillway and sluiceway sections, leaves the left bank and crosses the river on the brink of the Little du Bonnet Falls, connecting with the power station which parallels the right shore line below the pitch. Ice sluices and embankment connect the power station with the high land on the right bank. Provision is made for future lockage facilities on this bank.

The head-water elevation has been fixed at 808, with the tail-water at 762 previous to the blasting out of the Whitemud Falls, and 752 subsequent thereto. This secures a head of 46 ft. for the preliminary, and 56 ft. for the final installation.

The initial installation is figured on seven 10,000-h.p. turbine units, utilizing 12,000 sec.-ft. at 8/10 gate and 46-ft. head. This, on the same basis as set out above, will render available 47,100 h.p. at a capital cost of $79.40 per h.p. at the switchboard. An intermediate installation, comprising 12 units and providing capacity for 20,000 sec.-ft. at 46-ft. head, and producing 78,700 h.p., has also been estimated. The cost of the power at the switchboard for this intermediate installation is $68.90 per h.p. The final installation consists of fourteen 10,000-h.p. units, for the development of 20,000 sec.-ft. at 56-ft. head, the extra 10 ft. being secured by the removal of the Whitemud Falls. On the same basis as set out above, 95,500 24-hr. h.p. will be available at a cost of $70.70 per h.p. on the switchboard.

(e) Pine Falls Site.—The Pine Falls development will concentrate the natural drop of the Pine and Silver Falls, giving a head of 37 ft. The dam runs diagonally across the river from the right bank, and joins directly to the power station, which forms a continuation of the dam. The power station is connected with the high ground on the left bank, by sluices and embankment. Provision is made for lockage facilities on this bank.

The head- and tail-water elevations have been placed at 750 and 713 respectively. As the tail-water is practically Lake Winnipeg level, it will vary from year to year with the level of the lake. The installation in the power station has not been finally determined, but the following estimates of the capital cost of the power are considered to be fairly close. The initial installation will provide for the development of 12,000 sec.-ft. at 37-ft. head, i.e., 37,900 h.p. on the 75% efficiency, 24-hr. basis, at a cost of $80.30 per h.p. on the switchboard. The final installation provides for 20,000 sec.-ft., and renders available, on the above basis, 63,100 h.p. at a cost of $70.70 per h.p. on the switchboard.

Summary of the Power Possibilities of the Winnipeg River.—Fig. 4 is a tabulation of the powers, developed and undeveloped, of the Winnipeg River, under regulated and unregulated conditions. The undeveloped power is considered on a 75% efficiency, 24-hr. basis, and the capital cost per h.p. is given in terms of this power, estimated to the switchboard in the power house.

Attention is called to the circular diagrams on Figs. 5 and 6 as illustrating, in a graphical manner, the developed and undeveloped power conditions along the river under unregulated and regulated river flow.

Diagrams Showing the Developed and Undeveloped Powers at the Various Sites on the Winnipeg River. (Undeveloped Sites Considered at 75% Efficiency with 24-hour Power.)

Future Economic Value of the Winnipeg River Powers.—With regard to the future economic value of the powers of the Winnipeg River, a report was made to the Department of the Interior in September, 1911, by Mr. J. R. Freeman, one of the consulting engineers retained by the Department for advice in connection with water power matters. Mr. Freeman says:—

"**Economy and Conservation.**—While water power opportunities on the Winnipeg River may have a very few years ago appeared so far beyond possible use that ordinary economics were unnecessary, it is, I believe, plain to-day beyond serious question that all of the remaining opportunities for power should be carefully conserved and only developed under such conditions as will not necessitate any great waste or the impairment of remaining opportunities.

Second Pitch of Grand du Bonnet Falls, Winnipeg River.

"Sundry remarkable electro-chemical processes have been very recently invented, which promise to be of great future benefit to agriculture and other arts. Fertilizer for farmers' use is now being successfully made by electricity from the nitrogen of the air, and great water powers in Norway are now being developed for these purposes in addition to those already in use, and recent developments have also been made of similar processes not far from the southern boundary of Canada.

"The great uses of hydro-electric power at Niagara Falls and at the Sault, for making aluminum, carbide for gas lighting, bleaching powders, and caustic soda and sundry other important products, were unknown only a few years ago. Indeed, it may be said that every one of the electro-chemical processes now located at Niagara Falls has been invented since the first of the large hydro-electric power stations was built at that point. It is idle to say that the era of important electro-chemical invention is yet more than begun and with the many able investigators now earnestly working on these lines in many parts of the world, great additional discoveries and commercial developments in the application of cheap electric power are almost sure to come, particularly in metallurgy or the reduction of ores.

"**The Winnipeg Market Now Fully Supplied.**—The City of Winnipeg will soon have all the power that it needs for public service corporation and for any conceivable manufacturing purposes likely to locate in or near the city for perhaps a score of years to come, from the railway company's plant already in use and to-day understood to be delivering about 22,000 horse-power and from the new municipal hydro-electric power plant at Point du Bois, now nearing completion, with a first installation of 26,000 horse-power and with works planned to be extended to more than three times that capacity.

"Thus these two plants will be capable of delivering to Winnipeg more than 100,000 h.p. of 24-hour electrical energy, a quantity which can be best appreciated by a statement that it is far greater than the total water power at Lowell, Lawrence, Manchester and Holyoke combined.

"**A Possible Field for Use.**—The best use that I can foresee for the vast water powers now remaining untouched upon the Winnipeg River is as the basis for founding three or four new industrial cities based upon electro-chemical industry, very much as water power was the basis for creating, years ago, the cities of Lowell, Lawrence, Manchester, Holyoke, Bellowa Falls, and as in recent years it has brought together hundreds of new homes at Niagara Falls, Shawinigan Falls and at the Sault.

"We cannot to-day say what the line of manufacture may be, for the electro-chemical arts are still in a state of ferment and creation. It has already been demonstrated that by electric smelting, steel for the manufacture of tools can be made having a quality and value difficult to obtain otherwise. Fertilizer in the form of artificial saltpetre is being produced commercially in large quantities under German processes, while carbide, carborundum, aluminum and numerous other useful products are being made by electro-chemical means in great quantity at Niagara and elsewhere, and sooner or later the time will come when fertilizer will not be scorned by the farmers of the Canadian Northwest. There is promise of new metallurgical processes for which cheap electricity is a necessity and the price per pound of several of these products is such that they could stand a considerable cost of freighting to their markets and such that a power capable of being developed in so vast quantity at one point and at so low a cost per horse-power as appears practicable at three of the sites along the Winnipeg River, will surely be very attractive.

"**These New Industries Must Locate Close to the Water Fall.**—These electro-chemical processes, when carried on in the large commercial way, demand that the work be done close to the point where the power is generated, for two reasons: First, because although the air-saltpetre process uses alternating current at low voltage which cannot be transmitted to great distance with anything like the facility of alternating current; and second, because in order to attract these processes it is necessary that the cost per horse-power be the very lowest and not overloaded by the cost of long transmission lines or the percentage of power necessarily lost in such transmission.

"Wherever a new industrial centre with some hundred of homes can be established in the wilderness within a hundred miles of Winnipeg, it will add to Winnipeg's prosperity in a degree but little less than if located within its borders and will add to the prosperity of the province by the new opportunities that it brings for employment, the diversity that it adds to its business interests and by the money that it will put into circulation. It is plain that many of the recent power developments made in various parts of America, from which the power is transmitted long distances, to displace steam power in populous centres results in putting a much larger number of men out of work than it sets at work. Such a development is of less benefit to the country than the early water power developments which were used locally in erecting the cities already named, in building hundreds of new homes and in setting thousands of men working at new opportunities."

THE SIEVING OF CEMENT.

The determination of the degree of fineness of a sample of cement, usually a part of the specification and contract upon which the material is purchased, is an operation where accuracy of the results is often in dispute. The U.S. Bureau of Standards has recently carried out tests to ascertain what order of discrepancy may be expected when made by the standard routine method of sieving. A paper by Rudolph J. Wig and J. C. Pearson, just published by the Bureau, gives the following conclusions as conservative estimates deduced from the results of these tests:

1. Employing the present standard method of sieving, the greatest attainable accuracy in single fineness determinations of normal Portland cement on a standard No. 200 sieve, that is, the greatest attainable accuracy in checking uniformity of samples, is about 0.2 per cent.

2. "Standard" No. 200 sieves may differ in their sieving values by considerable amounts, such that their corrections to the ideal No. 200 sieve may be at least as great as 0.7 per cent.

3. Errors of at least 0.5 per cent. may be looked for in single fineness determinations of normal cements on a standard No. 200 sieve when made in the usual routine manner.

4. Deviations exist in the sieving values of "standard" No. 100 sieves, of a magnitude, roughly, one-half the corresponding values for No. 200 sieves as given above.

5. "Personal equation" appears to be appreciable in hand sieving, as in most laboratory operations, the observed values being as great as 0.3 per cent.

6. The rating of a sieve by some system of demerits assigned from direct measurements appears to be an interesting possibility, and worthy of further study. Should a system be worked out to give reliable indications, say, within 0.2 per cent. or 0.3 per cent. of the observed sieving value of a sieve, it will add greatly to the value of the certificate now furnished with standard sieves.

It seems evident that both sieving tests and the interpretation of measurements on sieves are subject to considerable discrepancies, and the question arises as to whether some other more reliable method of determining fineness can not be made available. The sieve at best is a measure of the coarseness of finely ground material rather than the fineness, and experiments now in progress at the Bureau of Standards indicate that air separation will offer a more satisfactory means of determining fineness than mechanical sieving.

It may be stated that a tolerance of 1 per cent. from the specification should be allowed with the No. 200 sieve and 0.5 per cent. from the specification with the No. 100 sieve, every care being taken to conduct the test in strict accordance with standard methods. These tolerances should be considered as minimum values since they are based upon the results obtained by careful and experienced observers; therefore it should be emphasized that greater differences are possible in ordinary routine testing.

Scope of the Tests.—Discrepancies in determinations of fineness may be attributed to: (*a*) Differences in the standard sieves; (*b*) the "personal equation" of the observer; (*c*) lack of uniformity in the samples; (*d*) the residual differences when the three foregoing sources of error are, as far as possible, eliminated.

Considering the last mentioned first, it is evident that the experienced and careful worker, using a high-grade sieve and sieving samples of a well-dried and thoroughly mixed cement according to a fixed program, can by repeated trials determine a maximum limit of tolerance for residual differences. When this has been established, the same observer is in a position to check uniformity of samples of other cements—that is, he may check their uniformity only with an accuracy not greater than his own maximum limit of tolerance. There is at present, so far as we know, no simpler method of detecting lack of uniformity in finely ground material.

Following the results reported below, an attempt has been made to establish:—

1. What variations in fineness determinations are permissible under the most favorable conditions.

2. What variations may arise from differences in the "standard" sieves themselves.

3. What error may be looked for in a single fineness determination on a standard sieve as performed by an ordinary laboratory worker of average experience.

4. Whether variations from the standard method of sieving are appreciable.

5. Whether "personal equation" is appreciable in the limited number of tests made.

6. Whether an arbitrary system of "demerits" determined from careful measurements of a sieve is a reliable indication of its sieving value.

Features of the Tests.—The tests were made on a lot of sieves submitted for the purpose by two well-known firms. Four men made independent determinations of fineness on 24 of the sieves, while two men made the majority of determinations on the remaining sieves. The cement used was a good brand of normal grade Portland, which was first thoroughly dried, screened through a No. 20 sieve, and finally mixed by long-continued rolling on a large sheet of stout manilla wrapping paper. The determinations were made according to the standard method of sieving described in the United States Government Specification for Portland Cement, as follows:

The determination of fineness should be made on a 50-gram sample, which may be dried at a temperature of 100° C. (212° F.) prior to sifting. The coarsely screened sample (cement is ordinarily screened through a No. 20 sieve before mixing for routine tests) should be weighed and placed on the No. 200 sieve, which, with the pan and cover attached, should be held in one hand in a slightly inclined position and moved forward and backward in the plane of inclination, at the same time striking the side gently about two hundred times per minute against the palm of the other hand on the upstroke. The operation is to be continued until not more than 0.05 grams will pass through in one minute.

While the experienced worker always develops some peculiarity in his method of sifting, which contributes to or determines his "personal equation," undoubtedly the chief factor to be guarded against is carelessness. This factor may explain to some extent the rather wide variations observed, but it may be safely assumed that the sum total of carelessness on the part of those who participated in the tests is less, rather than greater, than that made in normal routine work, and it is believed that the average results represent what may be expected from experienced routine workers in similar laboratories.

In the following tables the observers are designated by letters and the sieves by numbers:

Table I.—Results of Sieving Tests Made by Four Observers on 12 Standard No. 200 Sieves.

Sieve.	Observers. A	B	C	D	E	Average.	Max. var. from average
1	80.30	79.72	80.40	80.24	.....	80.16	0.44

Average....	80.30	80.05	80.35	79.77	80.17

Table I. shows the results obtained by four observers using the same cement on 12 standard No. 200 sieves. The figures are percentages of total cement passing the sieves.

An approximate value of the range that may be expected due to differences in the sieves may be obtained from the averages for each sieve, which are taken as the most probable sieving values. The highest is seen to be 81.03 per cent., the lowest 80.16 per cent., range 0.87 per cent. A "standard" sieve according to these results, may therefore differ from the mean value of a number of good sieves by nearly 0.5 per cent. It is to be borne in mind, however, that the mean value of a number of good sieves will generally be greater than the amount passed by an ideal No. 200 sieve, since the prescribed limits of tolerance allow greater latitude below 200 meshes than above. Thus, careful measurements of cloth on sieve No. 1 showed this to be the nearest of the lot to the ideal No. 200 sieve, and repeated fineness determinations with this sieve showed that its most probable sieving value was about 80.30 per cent., which is 0.3 per cent. less than the observed average value for all the sieves. It follows, therefore, that a "standard" sieve may have a true correction to the ideal sieve of as much as 0.7 per cent.

The last column of Table I. shows that the error to be looked for in a single fineness determination is likely to be at least 0.5 per cent., a figure which will, of course, vary with the reliability of the observer. A search through Table I, however, will show that all the observers have missed the average value on one or more sieves by more than 0.4 per cent.

A roughly approximate value of personal equation may be obtained by averaging all the determinations made by each observer and comparing this with the mean value of all observers. The values are given in the last line of Table I. The number of observers is too small to establish this factor with any certainty, but for observers A and D, whose averages show appreciable deviations from the others, it may be noted that 8 times out of 12 A's value is less than the mean value for the sieves, and 8 times out of 12 D's value is greater than the mean value for the sieves.

Table 2 represents the results obtained by a single observer on sieve No. 1, using five slightly varying methods of sieving, each method being given three careful trials. These methods include the deviations from the standard method of sieving which are sometimes permitted in fineness determinations. Col. 1 contains the results obtained by moving the sieve back and forth 200 times per minute, that is, according to the standard specifications. Col. 2 contains the results obtained from sieving at the rate of 250 strokes per minute, this rate requiring, of course, short quick strokes. Similarly Col. 3 contains the results obtained by sieving at the rate of 150 strokes per min., the strokes being relatively long and slow. Col. 4 contains the results obtained by sieving according to standard specifications, using, however, a single brass washer about ¾ in. in diam. to aid in breaking up the small lumps of fine material. Col. 5 shows the effect of using six 3/16-in. steel balls in place of the washer.

While the determinations are too few in number to show decided differences, the order in which the results actually occur is interesting. From the lowest to the highest amounts passing the sieve, the order is as follows:—

1. Sieving with a washer on the sieve.
2. Sieving with steel balls on the sieve.
3. Sieving at 250 strokes per min.
4. Sieving at 200 strokes per min.
5. Sieving at 150 strokes per min.

Thus the trials indicate that the simplest and easiest method—that is, sieving at the moderate rate of about 150 strokes per minute—gives the maximum percentage of cement passing the sieve. The somewhat erratic results obtained by the use of the washer and the balls, which might have been anticipated to give the highest values, are seen to be the lowest; and the variations are to be accounted for by the uncertainty of the stopping point. The use of washer and balls seems to increase the irregularity of the amounts obtained in successive minutes toward the end of the sieving, so that one may naturally stop somewhat earlier than he would if the amounts were decreasing regularly. It is evident, of course, that for every minute over or under sieving, the error introduced is approximately 0.1 per cent. On this basis the maximum limit of tolerance for the best work can hardly be less than 0.2 per cent., since the most careful observer may readily be one minute short or one minute over.

The fact that appreciably more cement passes the sieve at 150 strokes per minute than at 250 strokes per minute is no doubt due to the more rapid horizontal motion of the sieve in the latter case, whereby particles just under the smallest size retained have less opportunity to fall through the sieve openings than when the sieve is moving at the slower rate.

In all sieving tests it is tacitly assumed that the specifications need not be closely followed until the greater part of the fine material has already been sieved through, that is, the final result is assumed to be independent of the manner in which the first part of the sieving has been performed. This is no doubt justified in

hand sieving when no washers or balls are used to hasten the process, but one may well question the assumption when vigorous methods are used, as in most routine work. In all trials reported in Table 2, the specifications were followed throughout the entire time of sieving.

It may, of course, be possible to form an estimate of the relative sieving value of a sieve from the direct measurements made upon it of the number and diameters of the warp and shoot wires, and the uniformity of spacing of the wires. The establishment, however, of a hard and fast demerit system for calculating the sieving value involves much guesswork, and the attempts thus far made at the Bureau of Standards to devise such a system have been only partially successful. It is not, therefore, worth while to go into the details of the manner in which the demerits have been assigned other than to state that consideration was given to all factors which affect the variations in size and distribution of the openings.

Table III.—Relation Between Value of Sieves as Actually Tested and Estimated Value Based on Sieve Measurements.

Personal equation	—.13	.02	+.03	—.15	....	.....	...

Table IV. is similar to Table I., containing the results obtained by four observers using 12 "standard" No. 100 sieves. The same method of examination enables us to state that a single determination of fineness on the No. 100 sieve is likely to be at least 0.2 of 1 per cent. in error. This value is, of course, less than the corresponding value for the No. 200 sieve, owing to the smaller quantity of material of this grade, which therefore gives a more definite stopping point in the sieving. Similarly, the range of differences that may be expected between standard sieves is less than that for the No. 200 sieves, being in this case from 96.46 per cent. to 96.73 per cent., of 0.27 per cent. The maximum correction of a "standard" No. 100 sieve to the ideal No. 100 sieve therefore appears to be of the order of 0.2 per cent.

A striking agreement is also noted between the "personal equations" as given in Tables I. and IV., the operators being the same in each case.

SUPPORTING TRACKS DURING CONSTRUCTION WORK.

The bearing on the total cost of work which is had by the design and construction of temporary structures supporting railway tracks under traffic, while work proceeds underneath—for instance, in the building of street or highway undercrossings—was shown at the recent convention of the American Railway Bridge and Building Association. Work was described at various points on the lines of the Lake Shore and Michigan Southern Railway, where three systems of support were successively required as the work proceeded.

At Sandusky, Ohio, a street crossing seven tracks at grade was to be carried under without altering the track profile. The solid rock surface was about halfway down and above this were boulders and hardpan. Pile bents were built, the piles being driven to a stop. In the floor system supporting the tracks were incorporated two sets of stringers, one spanning from bent to bent and the other balanced on the bents. As the excavation proceeded ridges were left to protect the piles, the intervening spaces being taken out to solid rock. Some of the piles were found broken, and in such cases short posts on sills were pushed in to replace them. When the rock surface between bents had been reached frame bents were erected in the middle of the spaces, catching the ends of the secondary system of stringers, which, like the primary system, were designed to carry the full load. The pile bents were then removed, except the caps, which were left bolted to the stringers; then the remainder of the loose material was cleaned away and trenches cut to the full depth required for the excavation, the trenches being directly in the line of the original pile bents and the whole system being so spaced as to avoid the permanent abutments and the intermediate piers. New frame bents were then constructed in the trenches and the load transferred to them, after which the bents on the higher level were in turn removed.

A somewhat different treatment was required at Cleveland, where a street crossed six tracks at grade on a sharp skew. There, as at Sandusky, it was proposed to cut the street under without changing the track profile, but the rock surface was only about 4 ft. below subgrade. Of the four main tracks the two inferior ones were temporarily put out of service and the soil underneath excavated to rock. Two sets of stringers were used as at Sandusky, the secondary set, however, being placed on top of instead of alongside the primary set. The stringer system thus filled most of the space between subgrade and rock, and the first system of supports consisted of sills and blocks spaced 20 ft. apart. Afterwards the procedure was similar to that at Sanduskv, the second set of bents being carried in trenches about halfway down and the third set resting on the bottom of the finished excavation.

The cost of the Panama Canal to May 30, 1913, was $295,587,418.41. For the sanitation of the Canal Zone $16,132,056 was expended.

EXPERIMENTS IN PRE-HEATING CLAYS.

IN Memoir No. 25, Geological Survey, Department of Mines, Canada, Dr. Heinrich Reis and Mr. Joseph Keele have submitted Part II. of their report on the clay and shale deposits of the Western Provinces. The 108-page book is well illustrated, and has an abundance of new data concerning the properties and characteristics of the formations to be found throughout the West. One chapter, by Mr. Keele, deals entirely with experiments in pre-heating clays, from which we make the following extracts:—

Among 120 samples of clay and shales collected during the seasons of 1910-11 in the Great Plains region, 28 of them, or about 23%, cracked in air drying after being moulded. These defective clays occur principally in the Belly River and Edmonton formations, and in the upper part of the Cretaceous, but some of the Laramie clays have the same fault.

They are frequently found in localities well situated for transportation; they are easily worked, and occur in great abundance. They would, therefore, be of great economic importance if they could be utilized, as many of them will make fireproofing, and some even can, we believe, be manufactured into sewer-pipe if their tendency to crack while drying can be overcome.

Several beds of these clays and shales could be manufactured into facing bricks by the dry-press method, but it is impossible to use them for the many important structural wares which involve the use of the wet-moulded processes.

During the progress of the laboratory work on the samples of these clays collected in the field, the writer was confronted with the difficulty of preparing test pieces from them for the purpose of observing their behavior under fire. The clays absorbed a great deal of water in tempering, afterwards forming a stiff pasty mass which was tough and sticky and hard to work. Shortly after being set to dry the moulded shapes cracked, even small test pieces splitting badly in the ordinary laboratory temperature. The surface of a full-sized brick readily became dry, and developed a perfect network of cracks, which deepened and widened as drying progressed, while the inside remained moist for several days. The use of substances which would coagulate the clay was tried to cure this cracking, being careful to use materials which were cheap and readily available, so that if the remedy were successful it could be used on a commercial scale. Of the various acids and alkalis tried, common salt to the amount of 1% added to the clay seemed to give the best results. The salt kept the surface of the bricklets moist while the water was working its way out of the body.

Full-sized bricks made from some clays thus treated would dry safely in the ordinary room temperature, but many clays would not, and few of the salted clays would stand even moderately fast drying. Furthermore, the stickiness and soap-like qualities of the clays were not ameliorated to any appreciable extent by the mixture.

The next method which suggests itself was the use of non-plastic materials like sand or grog. River sand, ground quartz, and calcined clay were successively used. These were added to the clays in varying amounts up to 50%.

The mixtures with sand failed in every respect, and although the grogged clay could be safely dried in some instances, and burned to a good body, the bad-working qualities of the raw clay were still in evidence.

Professor Orton,* who was experimenting on some clays of the Edmonton series at the same time as the writer, was unsuccessful in overcoming their drying defects by the use of either chemical coagulants, or additions of non-plastic materials. There remained then the method described by Professor A. V. Bleininger for treating clays that cracked in drying, by pre-heating them at various temperatures.

Pre-heating experiments were done on several of our clays, and the results arrived at seem to prove that this is the best method so far, for dealing with the difficulty. The data for six samples of clay from localities widely apart are here given. Clays of these types may be expected to recur frequently in other localities throughout the region we are dealing with. Numbers 1644 and 1755 are used for making dry-pressed bricks, but the other samples are from unused deposits.

1644—Dark grey massive clay, underlying a lignite seam, Estevan, Sask.

1755—Light grey massive clay, Coleridge, Alta.

1765—Dark grey soft shale, underlying a lignite seam, Tofield, Alta.

1675—Light grey hard shale, overlying coal seam, Oldman River, Alta.

1800—Soft olive shale, Gwynne, Alta.

1796—Soft shales interbedded with streaks of sand, Camrose, Alta.

The clays were heated in a small rotary drum, made of sheet iron, and having baffles projecting from the inside to keep the clay well stirred up and evenly heated.

A stationary sheet iron hood enveloped the drum except where openings were left for the gas flames to enter. The drum, which was revolved by hand, was provided with a hollow axle, through which a pyrometer tube was inserted. About ½ to ¾ hr. was generally taken to bring the clay to the required temperature, the latter being easily kept constant during the time allotted for treatment.

The length of time allowed at each temperature was 15 min., each clay being kept for this period at successively higher temperatures until it yielded to the treatment. Other trials were made of 30 min. duration at certain temperatures, to show the effect of time.

The latter results show that it is possible to obtain effects at lower temperatures with increased time, similar to those given in the shorter time at higher temperatures, but this appears to be true only within certain limits, as Professor Orton's experiments show that some of these clays were not improved by exposure for 1½ hrs. to a temperature of 400° C. Steam was given off freely from the heated clay at all temperatures up to 500° C. The fumes evolved at higher temperatures smelled strongly of sulphur and hydrocarbons, which was probably due to the dissociation of particles of pyrite and driving off of bituminous matter.

When the heating was completed all the clays except No. 2 were much darker in color than in the raw state, being dark grey to almost black.

Clay No. 1755 yielded at a comparatively low degree of heat treatment, probably due to its containing a relatively larger amount of grains larger than clay substance than any other of the samples tested.

The tenacity with which clay No. 1765 clings to its plasticity under the action of heat is remarkable, as that property was not affected to any great extent even at the

*Edward Orton, Jr., Experiments on the drying of certain Tertiary clays, Trans. Am. Cer. Soc., Vol. XIII.

highest limits of the experiment. It would no doubt succumb to a more prolonged exposure at 550°. or it might be successfully treated at 600° for 15 min. The latter was not tried, however, as it is possible that the amount of preliminary heating that could be economically applied to this or similar clays in practice was already exceeded.

The results given by sample 1675 show the slight margin in time that exists between the proper and unsuccessful handling of some clays.

After the 30-min. treatment at 550° this clay was sandy in texture, and could not be moulded into shape, while after the 15-min. treatment its defective qualities were quite unimpaired.

The precise time, then, for the clay at this temperature appears to be either 20 or 25 min., but. as will be explained later, the 30-min. treatment was not fatal.

The results of previous experience without any special apparatus, showed that the clays would require a high degree of heat treatment, but to avoid mistakes all the clays were heated to 350° C.; however, since no change occurred in any sample at this temperature it is unnecessary to include it in the table.

The test pieces made up for the drying tests were 2½-in. cubes, as there was not a sufficient quantity of the various clays in stock to make full-sized bricks. The cube, however, has a greater volume for the amount of surface than any of the brick shapes.

The driers used in the experiment consisted of small chambers attached to the steam heating apparatus of the building. The maximum temperature that could be obtained in this way was about 65° C., the pieces being dried in from 24 to 36 hrs. Although faster driers are used for some clays in practice, it was decided that if the clays can be worked and afterwards dried safely at the above temperature, that the object of the experiments had been attained.

The pre-heating causes marked changes in the character of the clay, the most important for practical purposes being the change from a tough sticky mass, having undue shrinkage and abnormal cracking in drying, to an open granular body which can be easily worked and rapidly dried.

The pre-heated clays require considerably less water for mixing than the raw clays, consequently the air shrinkage in the clays thus treated is greatly reduced, as shown in the following table:

No.	Average per cent. air shrinkage. Raw clay.	Pre-heated clay.
1644	9.6	4.0
1755	7.0	0.0
1765	8.7	5.0
1675	8.9	5.0
1800	8.5	3.6
1796	8.8	4.0

Another striking advantage gained in pre-heating is seen when burning the test pieces. Those clays which were subject to black coring and swelling were completely cured of this trouble by the pre-heating treatment. This is probably due to the change in texture which the clay undergoes when pre-heated, giving a more open body from which the gases evolved in burning can escape freely, and also to the driving off of some of the carbonaceous and sulphurous components.

The effects obtained by pre-heating to the above temperatures are not permanent.

The plasticity of the clays Nos. 1675 and 1800, apparently destroyed during the course of the experiments, was restored again by allowing those clays to remain in an excess of water for 24 hrs. Sufficient water was then evaporated, so that the clay could be remoulded, and set to dry. No. 1675 would still stand fast drying, but No. 6 cracked both in the fast and slow drier.

Again, when the cubes made from No. 6 were dried, reground and wetted for the third time it was found that this clay had regained all its pristine plasticity and stickiness, and small bricklets then made from it cracked while air drying at room temperature quite as badly as the raw clay did.

In the table given above will be found analyses of several of the clays described in this chapter. They were made by G. E. F. Lundell.

The greater part of these clays is made up of quartz grains of varying degrees of fineness, as many clays are, and the chemical analysis furnished no clue to their erratic behavior.

About 20 ft. below the beds from which sample No. 1796 was taken a seam of about 2 ft. in thickness of the clay known as bentonite occurs. This variety of clay is of yellow color when fresh from the bank, but assumes a dirty white color on exposure. It is fine in texture, exceedingly smooth, and forms a very soft soapy mass when mixed with an excess of water. It has an extraordinary capacity for absorbing moisture, being capable of taking up three times its weight in water.

The clay possesses marked detergent properties, and was used in the early days of the North-West by Indians and Hudson's Bay Co. employees as a substitute for soap.

This material was rejected as unfit for any burned clay wares, but an attempt was made to dry some bricklets made from it, in a moist atmosphere. After three weeks of gradual drying the bricklets showed abnormal cracking and very high shrinkage. Although none were observed on the outcrop, it is possible that some thin streaks of bentonite were included in the beds sampled for No. 1800. Certain of the sand beds of the vicinity were found to possess plasticity, and some decidedly silty beds will crack in slow drying.

As a good deal of the material which composes these beds is derived from the erosion of the lower Cretaceous which contains bentonite beds, it may be assumed that this material, being part of the product of erosion, was re-deposited and distributed through many of the later beds.

It occurred to the writer that some simple scheme of washing might be adopted to separate out the pasty constituent from these clays.

As an experiment, one pound of ground shales from sample No. 1675 was well stirred up in about a gallon of water and allowed to settle for two hours, the water and suspended matter being then drawn off. This operation was repeated, and the residue allowed to dry. When the residue had dried, it was found to consist of a badly cracked yellow paste about half an inch in thickness, forming a crust on top of dark grey sand and silt. The yellow paste had all the appearance and characteristics of bentonite or soap clay.

The shale, when dry, was found to have lost 25% of its weight, presumably all of it being pasty matter held in suspension and drawn off with the water.

The plasticity of the shale was much reduced by the washing, but it cracked almost as badly as ever in the 65° drier. It would dry intact though, in room temperature.

That the presence of bentonite is a potent factor in producing air cracks, was proved by the following experiment. Ten per cent. of bentonite from Camrose was added to a coarsely ground paving brick shale from Elmira, N.Y. The cube made from this mixture cracked badly in the 65° drier. The Elmira shale will stand fast drying at 85° C.

Between bentonite as an extreme case and clay No. 1755 as a mild example we have clays containing varying amounts of gelatinous paste, which allows the water to escape with difficulty from the body, and causes cracking while retarding drying.

The chemical analysis of bentonite (see table) showed that it possessed a large amount of hydrous silica; which probably causes that sticky type of plasticity and the trouble in drying.

Pre-heating has the effect of driving out the water from the hydrous silica, and causing the caking together of the dehydrated particles, which gives the granular texture seen in the clays thus treated.

Clay No. 1765 was washed in a similar way to No. 1675, but lost 75% of its weight and the residue cracked in drying.

The chemical analysis made of it shows only a small amount of hydrous silica, but this clay, notwithstanding the low amount of that ingredient, possesses all the pastiness of bentonite, and its tendency to crack is almost as pronounced.

A large percentage of this clay is in a very finely divided state, and much of it may be colloidal matter; perhaps organic colloids are also present. Then, in this case, pre-heating to sufficient temperatures has the effect of driving the water from the infinitesimal pore spaces between the minute grains, and the chemically combined water from the colloids. The minute particles, when deprived of their water envelope appear to adhere in sufficient numbers to form sizable grains.

The subsequent safe drying after pre-heating seems to depend on the fact that the water with which the clay was tempered escapes by evaporation in the driers before it has time to permeate the microscopic pores again and hydrate the colloid or siliceous content.

Clays which retain or regain their plasticity after the expulsion of chemically combined water have been recorded at various times.

H. E. Kramm* found that test pieces made from mixtures of kaolin and gypsum, kept for 8 hrs. at a temperature of 790° C. slaked down in water, and had lost little or none of their original plasticity.

Most of the clays can be made workable by the preheating process if commercial conditions allow of its use. This process involves the use of a suitable type of rotary kiln, a cheap fuel to supply the high temperatures at which these clays must be treated, a proper superintendence in controlling the process and the cost of extra labor. The samples on which the experiments were made have been selected from localities in which either coal, lignite, or natural gas is abundant.

Clay No. 1644 undergoes a slight pre-heating through a rotary drier in the brickworks at Estevan. This is done primarily to prepare the clay for dry pressing by getting rid of the superfluous moisture which it contains in the bank, but the treatment was also found to stop much of the fire checking to which the raw clay was liable. The losses from fire checking are still great, but a higher degree of heat treatment would probably do away with it entirely.

It is doubtful if the kind of apparatus in use at Estevan would give a sufficiently high temperature to drive off combined water and render the clay fit for wet-moulded processes.

*Trans. Am. Cer. Soc., Vol. XIII., p. 698.

The annual report of the mines branch of the Department of Mines, issued last November, makes the statement that Canada possesses gas and oil fields of considerable value, which, if developed, may rival those of the United States. Hitherto, oil as liquid fuel has been used in North America only in the United States, and the report states that there is no reason why Canadians should not also avail themselves of its advantages. It also points out that an increasing demand for liquid fuel has of late constituted one of the outstanding features in power development; and observes that, while the oil business has generally been viewed as a gambling enterprise, and many companies have conducted it as such, the days of taking great chances are past. Dealing with the possibilities of the different Canadian provinces, the experts in the employ of the mines branch, who have compiled the report, say that in Alberta deposits are considerable, but the cost of drilling is high. Of the Northern Alberta field, they point out, that it has as yet produced no oil in commercial quantities. The same is true of British Columbia and Manitoba. The district between Regina and Moose Jaw and the Alberta border in Saskatchewan is reported to offer chances for oil operators. The province of Quebec gives no indication at the present time of developing fields of either petroleum or natural gas. New Brunswick oil fields, however, show considerable promise, and of Ontario, the statement is made that "the production both of petroleum and natural gas is on the decline and the total depletion of the underground supply is approaching."

SOME WATERWORKS SYSTEMS IN BRITISH COLUMBIA.

Construction of the Port Alberni Plant.

IN August, 1913, the Vancouver Wood Pipe and Tank Company completed the construction of a waterworks system for the city of Port Alberni, B.C., a contract begun in the fall of 1912. This contract was awarded in September, 1912, to the Municipal Construction Company, Limited, as the company was then known, and was for a lump sum approximating $108,000. The work was to have been completed in eight months, but owing to delays in arrival of shipments of steel for banding the continuous stave pipe, the plant was not finally ready for operation until August.

The principal features of the Port Alberni waterworks system, which is a municipally-owned enterprise, are an intake dam of crib-work and rock construction, a supply main some 7¼ miles long, and a distribution

Port Alberni Waterworks—16-in. Continuous Stave Pipe Line.

service throughout the business and residential portions of the city of some 4½ miles of 6-in. mains. The intake dam was constructed on China Creek, the source of supply, and is about 200 feet in length. A difficulty which first had to be overcome was the construction of a road for the entire distance of over seven miles from Port Alberni to the dam along the pipe line. This was through a rough, heavily timbered country, where trees 6 ft. in diameter had to be cleared away. In some parts, too, rock work of heavy character had to be undertaken, and the nature and extent of this may be learned from the fact that the amount removed in the construction of the road totalled 6,000 yards of rock and over 22,000 yards of earth.

In building this road the line was brought to grade, as the pipe was laid at one side, next the bank, so that it was readily covered with earth turned down from the slope of the bank. One important part of the work was providing for six inverted syphons, necessary because of the contour of the pipe line, which crosses several deep ravines, almost canyons in one or two cases. Here the roadway constructed had to be raised up by cribbing and filling-in—in some places to a height of 20 feet, so that the extreme curvature of the pipe might not be exceeded. To accomplish this about 30,000 lineal feet of cribbing timber was used.

The continuous stave type of construction was used in the first 26,000 feet of the supply main, the diameter being 16 inches. A portion of the line is illustrated in Fig. 1. This pipe was made of Douglas fir staves, from seasoned, clear stock, 2 x 4 in., dressed in radial section to a thickness of 1⅝ in.

One of the most important features of continuous stave pipe construction is the connecting of the ends of the staves. This is done by means of a flat metal tongue, about 2 in. wide and 1-16 in. thick, inserted in a slot sawed in the ends of the staves, and projecting at each edge just far enough to engage the side of each adjoining stave. To ensure absolute uniformity in this work the company has perfected and patented a machine by means of which the work of slotting is done with perfect accuracy. Thus the pipe goes together in such a, manner that a uniformly smooth bore is secured throughout, which is the object to be most desired in construction. In assembling this pipe, steel bands ½-in. in diam. were used, and the average spacing was 2½ in. The pipe line was marked by a great many curves as well as by the six syphons referred to, and the result of the construction is a striking demonstration of the adaptability of the continuous stave type of construction for such a water main.

Steel pipe was used for the remainder of the 7-mile main, the first 7,300 ft. from the end of the continuous stave pipe being 12 in. in diameter, and the next 5,800 ft. being 10 in. As the total head due to the elevation of the intake dam, 614 ft. above sea level, would have been too great a working pressure for the system, reducing valves were installed on the 12-in. and 10-in. portions of the main, bringing the pressure down to an average of about 110 lbs. in the city.

For the 6-in. distribution mains, wire-wound wood stave pipe, made from selected Douglas fir, was used. House services from these were installed at the time of laying the mains, under the supervision of the city engineer. Fire protection and other needs have been very adequately looked after, and Port Alberni, one of the most westerly ports in Canada, and one with an optimistic future, now that railway connection to Victoria has been completed, is well supplied with water for a population of fully 20,000 people. It is a curious bit of British Columbia history that this new port on the west coast of Vancouver Island, was the site of the first saw-mill, and really the first industry located in the province. The mill, long since removed, was erected by Capt. Stamp, of Boston.

Salmon Arm and other Water Systems.—The activities of the Vancouver Wood Pipe and Tank Company have included another water system for a British Columbia city, Salmon Arm, in the interior of the province. Here, during 1913, the company installed a complete system several miles in length.

Supply was taken from Canoe Creek, under a head of 700 feet, which was broken with a 50,000 gallon stave tank. This tank was housed in a frost-proof octagonal building. It forms the direct supply for the city service, which is designed to be extended as the needs of population demand.

In 1912, just prior to commencing the Port Alberni waterworks, the company completed a large contract for installing over 55 miles of steel distribution mains for the waterworks system of Burnaby municipality, adjoining the city of Vancouver. In the years 1910 and

1911 the same company undertook, and successfully carried out, the contract for installing the new supply main for the city of New Westminster, some 74,000 feet of steel pipe, 25 inches in diameter. This pipe was laid from a new dam built by the Vancouver Power Company at Lake Coquitlam, in the mountains just east of Burrard Inlet. (See *The Canadian Engineer*, Jan. 13th, 1914.)

Last year the company secured three patents for use in connection with the making of pipe. One of these was on a new and improved coupling, the other two on machines used in turning out the staves and pipe. In the new coupling for wire-wound wood pipe, the features are a machine-turned interior bore, to match the turned tenon on the end of each section of pipe where it is inserted; and a galvanized flat band of steel on each end, covering a portion of the sleeve coupling, which is in other makes left bare, as the winding of the wire cannot be carried to the extreme end of the sleeve. The flat band is sunk flush with the surface of the couplings, which are greatly strengthened by it. This band is an added strength to the end of each joint of pipe, which necessarily has no wire on the tenons where they are driven into the couplings. The machining of the interior of the coupling is a very important improvement, as it does away with any lack of uniformity of the staves when assembled in the work of winding, and thus it allows of a much more perfect fit in connecting up the pipe.

MICROMETER METHOD OF SURVEYING WATER ROUTES.

By Robert B. Sinclair.

FOR the purpose of pushing ahead their various enterprises, some governments and many private companies are now mapping their watercourses, not hitherto covered by the land surveyors. The work must be carried on with a considerable degree of accuracy; but the speed with which it is carried through is not by any means the least important factor, and sometimes becomes an important problem.

In obtaining the required data for the mapping, the micrometer survey has been found to produce results which compare very favorably with the triangulation method and the traverse method in accuracy, and the time which is gained is often invaluable to the parties concerned.

Established Methods.—This class of surveying can be carried on by several different methods, e.g., triangulation, the traverse and the stadia. All of these methods lack what is frequently a great essential, namely, speed. The first two of them have been tried out on numerous occasions where they have been found to be impracticable. The enormous amount of work in the making of the traverse survey may be readily apparent to anyone conversant with it. Lines must frequently be cut through the bush and the traverse carried along the shore.

The triangulation method suggests something more feasible, but to one familiar with this class of work, it can be seen that great difficulty may be encountered in obtaining points which could be sighted on, owing to the numerous bays and overhanging trees.

The stadia survey is much more adaptable than either of the other methods, but it is lacking in one necessity, viz., the accurate reading of distances of 400 ft. or over. On account of this the triangulation method must frequently be applied to the survey in order to take in the longer readings.

Hence, the advisability of using an instrument which will eliminate the possibility of error in long sights, and will read the shorter sights with the same degree of accuracy, appears obvious. Such an instrument we have in the micrometer. It has been tried out by the governments and also by the surveying departments of the different railways, and has been pronounced a most suitable instrument for this class of surveying.

In order to obtain the readings, a target is used, composed of two discs mounted on a light rod and set at varying distances apart, according to the length of the sights taken. The ordinary distances to be sighted are from 300 ft. to 1 mile. The space between targets used for these readings is about 10 ft. Nevertheless, sights of 5 miles have been read with a very fair degree of accuracy. For these sights a base line of perhaps 100 ft. is chained and the targets mounted at this distance apart.

The telescope of the micrometer is equipped with a double glass which throws two objects on the plane of the diaphragm of the instrument. The two glasses are worked in the vertical plane by a micrometer screw. When the objects coincide the vernier of the instrument reads zero. In turning the screw the glasses slide along, focusing the target at different points on the diaphragm. When the two of the target faces coincide, forming only three target faces in all, then the glasses have slid along a certain set distance, which varies each time with the increase or decrease in the space separating the instrument from the target. We see then the relation which obtains between the turning of the micrometer screw and the distance to be measured.

In order to compile a table which gives the distances in relation to the micrometer screw, a base line of perhaps one mile is chained out previous to entering the field. Distances are laid off every 100 ft. up to about 500 ft., and then at every 300 ft. or so. At these points the readings of the micrometer are noted. The screw is turned first to the left and then to the right, and the mean of the readings deduced. By this means the table of readings is taken in relation to the distances measured by the chain. Any number between the distances not noted can then be obtained by interpolation.

When this means of determining the distance is resorted to, the survey resolves itself into a very simple operation. The engineer in charge may use two targets. The main line of the traverse is kept intact and readings, spiralling in different bearings from the station points, is perhaps the more advantageous method of procedure. It might be stated in conclusion that the method is approximately 14 times as swift as the triangulation method, and compares very favorably in accuracy with any of them.

Governor Glynn announced recently at Albany, N.Y., a plan which he has formulated to increase the [illegible] state from $1,200,000 to $1,800,000 per annum. The scheme is based upon the state taking absolute charge of the 4,400 cubic feet of water per second now available at Niagara Falls under the treaty between the United States and Great Britain. It is claimed by electrical experts that this water will produce 75,000 horse-power. Mr. Glynn's policy is that the state should either develop this power itself and sell it to consumers, or sell the water to companies for generating electricity. If sold at the present wholesale price of electricity in Buffalo, $16 per horse-power, 75,000 horse-power will bring a revenue of $1,200,000 a year. If sold at the present retail prices of electricity at Buffalo, $26.50 per horse-power, 75,000 horse-power will bring a revenue of $1,800,000 a year. Governor Glynn contends also that, inasmuch as the state owns the water to be diverted from the Niagara river, the state [illegible]

CITY WATER WASTE.

"CONSERVATION," published by the Commission of Conservation, Ottawa, draws a comparison between the cities of Europe and North America with respect to consumption per capita of water, and presents some remarkable figures tending to emphasize the inordinately high waste of water in American cities.

The tables below give figures taken from representative cities on both sides of the Atlantic, and furnish a good basis for such a comparison.

	Imp. gals. per head per day.
St. John, N.B.	200
Vancouver,	160
Montreal	120
Ottawa	190
Toronto	95
Hamilton	98
New York	100
Buffalo	270
Chicago	190
Philadelphia	175
Average	159.8
Vienna, Austria	14
Ascher, Germany	24
Basel, Switzerland	40
Copenhagen, Denmark	26
Hamburg, Germany	40
London, England	36
Liverpool, England	36
Glasgow, Scotland	72
Newcastle-on-Tyne, England	33
Hull, England	38
Nuneaton, England	18
Stirling, Scotland	53
Riga, Russia	21
Manchester, England	42
Devonport, England	40
Average	35.5

It will be seen from the above that the average consumption per head in America is between three and four times what it is in Europe. This tremendous difference can only be accounted for by assuming that the greater portion of the water consumed in New World cities is simply wasted. A consumption of 50 gallons per head per day ought to be ample for all purposes, and would still be about 43 per cent. greater than the European average. Taking the American average as 150 gallons, we see that cities on this side of the Atlantic are using 100 gallons per head per day more than is necessary.

This unnecessary waste increases the cities' financial burdens in many ways. The pumping and filtration plants must be of needlessly large capacity; far more power must be employed to force a large quantity of useless water through the mains; and the distribution pipes and also the sewers that carry the water away, must both be bigger than necessary. Mr. R. O. Wynne-Roberts, M. Inst. C.E., estimates that in a city of 250,000 population, the extra cost of water delivered would amount to $560,000, or $2,24 per inhabitant. Further, the difference in cost of sewerage and sewage disposal would be $420,000, or $1.67 per inhabitant. This means that the city's water rates are increased by $3.91 for every man, woman and child of the population, without any appreciable benefit being gained for the extra outlay.

Undoubtedly some of this waste could be eliminated by placing meters on all house services, and, indeed, this is a common practice in England, and has already been adopted by some United States cities. To avoid the cost of installing meters on each service and to detect leaks in the mains, Mr. Wynne-Roberts suggests that meters be placed on the mains in different parts of the city, so that the quantity consumed in various districts could be ascertained. This would localize waste, and, if combined with an efficient system of inspection, would materially reduce useless consumption at a less cost than metering all house services. For a city of 250,000, he considers that about twenty district meters would suffice, the estimates the cost as follows:—

15 per cent. interest and depreciation on meters	$ 7,500
20 inspectors at $1,200	24,000
1 superintendent	2,400
2 clerks	1,920
Rent, light, stationery and miscellaneous	2,000
	$37.820

or approximately $40,000 per annum.

Certainly some means should be taken to check the present reckless waste. If some cities would conserve their present water supply, there would be no necessity of new reservoirs and additional water supply for many years to come.

CANADIAN STEEL MANUFACTURING.

Engineering, London, England, contained an article recently on the steel situation in Canada, and a short history of its growth. To quote, the writer says:—

"It would almost appear that, if the present rate of progress in steel manufacture continues, Canada will be able soon, not only to supply her own wants as regards steel, but also be able to enter the markets of the world.

"Prior to 1902, Canada made very little steel. The output advanced from 26,084 gross tons in 1901 to 182,037 gross tons in 1902. Five years later, in 1907, it had reached 646,754 tons, and five years later still, in 1912, it increased to 853,031 tons, the largest output in its history. It is quite probable that in the present year Canada will make nearly 1,000,000 tons of steel, or more than the United States made in 1879. The steel output of Canada is largely in the form of ingots, over 96% of the total in 1912 being in this form, and less than 4% in the form of direct castings.

"The largest two centres for steel in the Dominion are Ontario and Nova Scotia. In 1909 Nova Scotia led Ontario by 28,201 tons, in 1910 by 11,943 tons, and in 1911 by 20,623 tons. In 1912, however, Ontario forged ahead by 1321 tons. Nova Scotia has within its borders the new and modern plant of the Dominion Steel Corporation, while Ontario has within its boundaries the large and modern plant of the Algoma Steel Corporation.

"Naturally, the output of finished rolled forms of iron and steel in Canada increased in the same ratio as steel ingots and castings. In 1902 the total rolled output was 161,485 tons. In 1907 it had increased to 600,179 tons, and in 1912 to 861,224 tons, the maximum. Much the larger part of the total was steel—about 87.5% in 1912. Rails formed almost one-half of the total rolled output of the Dominion in 1912 over 40.2%.

"It was not till 1902 that Canada began to manufacture steel rails on a large scale. In that year it made 33,950 tons. Its output in previous years had seldom exceeded 800 or 900 tons. In 1912 the rail output reached 423,885 tons, its best yearly record."

CONTENTS OF THIS ISSUE.

WATER POTENTIALITIES OF BRITISH COLUMBIA.

The investigation of the Commission of Conservation into the power possibilities of the rivers and lakes of British Columbia was dealt with to some length at the fifth annual meeting of the Commission in Ottawa last month. The chairman, Hon. Clifford Sifton, in his address outlined the progressive steps from the beginning of the work in the Kootenay district in 1911, to the present. It was announced that the amount already done covers that portion of the Province between the Grand Trunk Pacific line and the International Boundary, including Vancouver Island. The assembled data on this part are being prepared for publication and will be issued during the present year.

British Columbia has contributed the most difficult problems with which the Commission has yet had to contend in its water-power study. Physical difficulties, causing unavoidably slow progress in survey work, have prolonged operations. Brevity of season during which profitable advancement can be made in reconnaissance investigation, lack of facilities for rapid movement over routes or from one route to another, and heavy expenses throughout, have also been factors occasioning more labor than one is apt to credit to such a great undertaking. One of the serious difficulties encountered, for instance, is that it is almost impossible for observers to avoid over-recording power possibilities of streams observed during high stages, and the flood stages in this province frequently occur much later in the year than in eastern Canada. The conditions affecting powers in this province are unique and do not closely correspond to those existent in other portions of the country. Glaciers, melting snow, and heavy rainfall abound, especially on the north mainland coast. Many storage possibilities, known and unknown, exist. While such factors contribute to enhance the value of powers, these conditions require special and very careful engineering investigation and expert handling in order to avoid encouraging developments that might not prove economical.

British Columbia has a number of streams which cross, and some of which recross, the International Boundary, and in connection with the utilization of these waters, there may be questions requiring consideration by the International Joint Commission. Some of these streams have large power potentialities.

The construction of railways in the lower portions of valleys debars development of many of what would otherwise have been fine water-powers, and, in some instances, highways have been constructed in locations which also tend to prevent development.

Incidentally, the protection of great fisheries dependent upon inland waters arises in this connection. An instance, witnessed last summer, of great numbers of salmon dying in the Fraser river, because of artificial blocking through railway blasting, has shown how carefully matters must be considered which may possibly affect the ingress and egress of valuable fish.

The report will also include references to the British Columbia law relating to waters, to various procedures under the law, and other cognate matters. The water legislation of British Columbia is quite advanced and has attracted international attention. *The Canadian Engineer* for January 8th, 1914, outlined the scope of a proposed bill for the formation of water municipalities for the conservation and distribution of water for irrigation purposes.

BUSINESS TRAINING FOR ENGINEERS.

It is not often that engineers are afforded such a clear analysis of the status of the profession in the public mind as Mr. Porter gives in his paper on page 320 of this issue. It is a subject about which much has been written. Engineers are constantly being offered opportunities for making introspective diagnoses of their professional qualifications.

There should be no resentment, however. There has never been an age when capable engineering talent was more in demand than the one in which we live. Present day problems in rural and urban development are not as simple of solution as they used to be. Besides the increase of necessities, the insistent demand for more rapid growth, greater undertakings and more costly enterprises, there is an entanglement of vested rights and powers associated with every problem. Its working out requires a talent that possesses much greater attributes than a panoramic view of engineering practice itself.

Compared with the older professions, engineering and engineering training are subjects of much controversy, and naturally so. The former are the product of old-established courses—the product of age itself, lacking which the engineering courses of to-day are without a certain coherence. This will come, but none too speedily if the criticisms which Mr. Porter cites are to be spared by the interested public.

The practical business sense, claimed to be one of the absent qualities, is undoubtedly as much the result of insufficient training as are any of the other discrepancies. Dr. Humphreys, President of Stevens Institute of Technology, a prominent engineer, and a high authority on the value of business training as a part of technical education, in one of his numerous writings, treats the subject in the following way:—

"Self-evident should be the truth of the proposition that the engineer ought to be a man of business, or at least informed of, and prepared to conform to, business conditions and business methods. When this proposition is squarely laid before them, it is self-evident to the majority of successful engineers and men of business. Business men, bankers, and manufacturers not infrequently refuse their confidence to engineers and experts as a class, because, under trial, some individuals have demonstrated their incapacity to meet business conditions; from the standpoint of the man of business their reports, advice, conclusions have required interpretation and readjustment or amendment.

"The man so far somewhat exceptional, who is able to bring to the service of his clients or associates a sound technical training, and the ability to meet business conditions proves by his comparative success the material value of this dual capacity. For the sake of the profession and the country at large it is important that this broader capacity should no longer be exceptional.

"To this end the professional educator and the engineer-student must better recognize the conditions to be met in practice. A general and definite demand on the part of the business world for engineers of such broader capacity would ensure the necessary reform in the separate schools of engineering and the university departments of applied science."

ONTARIO LAND SURVEYORS.

The Association of Ontario Land Surveyors will hold its annual dinner at the Engineers' Club, Toronto, on Wednesday evening, February 18th.

LETTER TO THE EDITOR.

Paving Streets With Creosoted Wood Block.

Sir,—Creosoted wood block paving, while comparatively new in many Canadian cities, is, in reality, not a new idea nor a new pavement. It is the result of combining two ideas, both of which in themselves had proved successful long before the first creosoted wood block pavement was laid. The ideas are: first, that of using wood as a paving material, and second, that of chemically preserving wood from decay.

For many decades wood was used as a paving material, sometimes in the form of cylindrical blocks cut from poles, best represented by the cedar block pavement. Both of these pavements gave great satisfaction because of their noiselessness and their adaptability to all kinds of traffic. But they were short-lived owing to the attacks of decay. Even in the face of this, many cities persisted in laying them because their many merits recommended them despite their lack of durability.

While wood block pavements were decaying and many cities were being forced to abandon their use for that reason alone, there was being developed a science which was destined to remove this objection to wood paving. This was the science of wood preservation. Railroads were preserving their cross ties and bridge timbers, while preserved piling, driven in the tepid waters of the Gulf of Mexico, where it was subject to the attack of the sea worm, was found to last almost indefinitely.

Many chemicals have been used to preserve wood, but only two seem to meet all requirements. They are creosote oil and chloride of zinc. Creosote oil, alone, is adapted to the preservation of wood paving blocks as, in addition to preventing decay, it also seals the pores of the wood, prevents the absorption of water, and does not leach out the blocks.

The application of timber preservation to the use of wood as a paving material has developed a street pavement which possesses more points of merit than any other material.

Many standdrds of excellence for a street paving material have been offered by writers upon this subject. The following is believed to be a fair standard by which to measure any material:—

(1) Its initial cost must not be so high as to make it unreasonable to the abutting property.

(2) Its durability must be sufficient to make its maintenance and ultimate cost low.

(3) Its surface must be smooth and hard and yet afford sufficient foothold to horses.

(4) It must be as nearly noiseless as possible, neither producing noise under traffic nor echoing other sounds.

(5) It must be so constructed as to be quickly laid and easily replaced when cuts are made.

(6) It must be of such material as to give off no dust or mud of its own creation.

(7) It must present no obstructions to cleansing, such as crevices, and be easily flushed and scrubbed.

(8) It must present a surface which offers no resistance to wheel traffic passing over it.

(9) It must not injure horses' legs and hoofs nor be injured by horses' calks or motor car traffic.

The initial cost of a pavement is an important item and yet not always as important as one might be lead to believe. In purchasing a street pavement, as in buying merchandise, the nature and length of service should be taken into consideration. The initial cost of a creosoted wood block pavement is so low as to make it reasonable for any street and the service it will give makes it the best possible investment for the property owner.

Durability is one of the prime requisites of a street pavement. Once a street is paved it is always to be a paved street. If the pavement is not durable the time will soon come when a new pavement must be paid for. The only test for durability is experience. In this regard, creosoted wood blocks have an enviable record. It is probably the only form of pavement that has never worn out or been replaced by another. Streets paved 12 or 14 years ago with this material are in as good condition today as they were the day they were opened to traffic. The splendid durability of the pavement makes its ultimate cost lower than that of any other form of pavement known.

In addition, the quality of service given by the creosoted wood block pavement is so much higher than that of any other form as to increase the advantage of the material over all others.

For that reason many cities have adopted the policy of paving down-town business streets, where traffic is tremendously heavy, with creosoted wood block. The practice was the result of the experience of London, Paris, and other European cities, and the results obtained in American cities have been fully up to expectations. The service given by the Broadway pavement in New York and several heavy traffic streets in Chicago proves the truth of this assertion. The peculiar quality to resist the effects of traffic possessed by creosoted wood blocks, placed with the grain vertical, gives the pavement first rank in point of durability.

Street pavements are laid to be travelled upon. Their chief object is to present a smooth surface for traffic and one which will bear the wheels of passing vehicles with little or no obstruction. The very purpose in view should preclude the use of any material which is not smooth and hard. Creosoted wood blocks possess this quality to a higher degree than any other material and yet afford a sufficient foothold for horses.

Every modern city is experiencing a laudable crusade against unnecessary noises within its limits. Everyone commends legislation preventing needless blowing of whistles and ringing of bells. Creosoted wood blocks make practically a noiseless pavement, frequently called the "silent pavement." Their adoption on many busy streets has resulted in increased rents for space in abutting buildings owing to the decreased noise by the traffic.

Yet, this success of a creosoted wood block pavement depends upon the way it is laid. If the blocks are laid on a solid foundation with ½ to 1 in. sand cushion and the pavement given plenty of room for expansion and pitched to prevent water getting under it, no trouble will be experienced and the pavement will be ideal. But when the pavement is laid crudely by men who are not familiar with it, trouble must always result.

When trouble of this kind does occur, it is published throughout the country by knockers, but if the actual fact, viz., that it was the crude way the pavement was laid, were known, it would be different, and people would understand why trouble has occurred. Every time a pavement heaves it is caused by the crude way the pavement was laid. Such is the case with the creosoted wood blocks laid on the Bank Street bridge at Ottawa, an account of which was published throughout Canada. It was a certainty that the pavement on the Bank Street bridge would expand and heave and that the blocks laid near the street car rail would either be loosened and come up, or break. No expansion joints had been put in the sides at each curb; the blocks had been laid too closely and instead of the blocks next to the rail having been bevelled and set right against the rail, strips of untreated timber merely had been put alongside of each rail. These strips would absorb water, expand, rot and disintegrate. The blocks were laid up tight against the strips, leaving a space of 1½ in. wide and 2 in. deep between the rail and the edge of the pavement between the tracks. During a heavy rain-storm the water would run down alongside the rail and get under the pavement, causing it to expand and heave.

The space between the pavement and the rail permits the wheels of carriages and light wagons to get into this space and loosen or tear up the blocks.

When properly laid, great success has been experienced with wood block pavements. In the large cities on this continent, each having laid hundreds of thousands of yards during the past 13 or 14 years, most of them are without any repair bills whatsoever to date. For instance, Hamilton, Ontario, has laid since 1908 over 285,000 sq. yds. and has had absolutely no repair bills. Compare this, for instantce, with the maintenance charges in Ottawa on the Bank Street pavement, from Wellington Street to Gladstone Avenue; and on the St. Patrick Street pavement from Dalhousie Street to the St. Patrick Street bridge. On the Bank Street pavement $49,848.66 was spent by the city since 1907, in addition to the maintenance expenditures made by the contractors. On the St. Patrick Street pavement, which was completed in 1911, the city spent $344.90 in 1912, and $1,696.88 in 1913; these amounts being in addition to the maintenance expenditures of the contractors.

A minor portion of these expenditures was on account of cuts for water and gas service, etc., but the cost of such cuts in dealing with a block pavement is greatly less than in dealing with a sheet asphalt pavement, such as was laid on the two streets above mentioned.

There has been considerable objection against creosoted wood block on account of Canadian climatic conditions, but when our pavements have been excellently successful in Moose Jaw, Denver, Minneapolis, Duluth and St. Paul, with a temperature running from top summer heat to from 30 to 60 deg. below zero in the winter, this point would seem to be answered by practical experience. In Ottawa, there is a properly laid pavement constructed of blocks that were merely dipped—not even properly creosoted—which has withstood Ottawa's climate for 8 or 9 years and it is in fairly good condition to-day. Several streets in Montreal have been properly laid with the dipped creosote wood blocks and these streets have been in fairly good condition with the exception of the blocks decaying on account of moisture getting beyond the point of oil.

In the city engineer's report to the council of Ottawa, he recommends the expenditure of over $3,000,000 for pavements, including merely $900,000 for permanent roads, namely, asphalt and stone blocks. In the light of statistics throughout Canada and United States, the repair bills on the remainder of the paving recommended would be enormous. Taking statistics in these countries, creosoted wood block pavements show no cost for maintenance with the exception of a few cities, and these few cities' statistics show maintenance cost almost nil. With the large amount of creosoted pavement laid on the principal streets in all of the larger cities in the United States, without having one pavement to show much of a wear over ⅛ in., should cause the engineers in the large cities of Canada to study carefully the qualities of creosote wood block pavements.

E. S. CLEMENTS,
Canada Creosoting Company.

Toronto, February 5, 1914.

THE CIVIL ENGINEER AND HIS RELATIONS TO SOCIETY.*

By Sam. G. Porter, B.A., B.S., M.Am.Soc.C.E.
Irrigation Inspecting Engineer, Dominion Government.

THE engineering profession is constantly meeting with these criticisms with regard to its members: 1st, That they are narrow in their mental training and habits. 2nd, That they are lacking in practical business sense. 3rd, That they are too little interested in the welfare of the community, or of society.

Let us ascertain what justification there is for these criticisms and how they should be met.

Narrowness.—Most engineering students confine their energies to strictly technical topics and take under protest what few subjects of general culture are forced upon them. As a consequence, they graduate and enter upon their work with little knowledge of what is termed the humanities. Having chosen a work that calls for technical skill, they naturally give their attention to the questions which will advance their usefulness and professional standing. Furthermore, their work, especially in their early years, usually leads them away from, rather than into, contact with social and commercial influences. They are pioneers, they are on the firing line, always advancing before they are permitted to enjoy the civilizing results of their own conquests. How natural it is, then, that they should acquire habits of thought and action out of sympathy with the social problems of the day—not in the sense that they are antagonistic to social and political progress, but are merely negligent and apathetic towards them.

To the extent that this habit predominates is the criticism of narrowness justified. Our profession is worthy of the highest possible respect; the possibilities of attainments in it are unlimited; a devotion to its ideals is to be encouraged; but to put it on a pedestal and overestimate its value to the exclusion of an appreciation of other things is undoubtedly a sympton of narrowness.

Lack of Business Sense.—If the first criticism is established, the second and third will naturally follow as corollaries.

Some of the qualities and conditions which have been pointed out above as tending towards narrowness, should, if properly applied, bring about the opposite result. The engineer is trained to be exact, to be accurate, to consider all the elements of a problem before arriving at a conclusion. He is in daily contact with inexorable laws. He must study nature's forces and combat or utilize them.

If, however, the exercise of these duties appeals to and develops only the technical side of his nature, a big part of the lesson is lost.

The failure of engineers to reach a high rank in practical matters and in influence is not always through want of technical attainments. More often it is through a lack of a broad outlook, an appreciation of the true proportions of things, a right perspective of practical values. The man who keeps his eyes too closely riveted to the technical problems is too apt to lose sight of the practical ones. He will not be trusted, and in fact, is not qualified to be trusted with the broader, practical questions which are usually the dominating ones. The man who solves them is the man who becomes boss.

*Read before the Calgary Branch of the Canadian Society of Civil Engineers, January 23rd, 1914.

In addition, then, to technical attainments, honesty and energy, which we will assume that most engineers have and which we will not here discuss, he must have (a) a broad outlook, (b) a right perspective of practical values, and (c) a well developed sense of personal responsibility. Without these qualities he may make a useful man, even a necessary man, but not a great man; not a leader. But if he has these qualities in addition to the first and is trained, as we presume he is, in the accurate observation and application of the laws of cause and effect, he should forge well to the front as a leader of affairs.

A Broad Outlook.—Too seldom is it the engineer who can be credited with the conception of the plans for big enterprises. Or, if he conceives them he seems to lack the leadership necessary for putting them into effect, and some trained intellect, with executive ability and a comprehensive grasp becomes the controlling brain of the head. Then the engineer is hired to work out the details of projects which others direct and benefit from.

A man of broad experience who knew whereof he spoke, said: "It is far easier to hire engineers than to hire men." Why is this true? Why do so many engineers allow themselves to be mere units in a system or cogs in a machine to be used by other men? Why, unless this second criticism is justified, have they not enough personality, enough force of character to direct and to control affairs instead of always being the hired man? Why do they not hire lawyers and financiers instead of always being hired?

It is estimated that more than 90% of the skilled labor of the world is directed by engineers. And yet the engineers are not in many cases actually the bosses. They are only hired superintendents taking their orders from the men who are blessed with this broad grasp of practical affairs and with ability for leadership.

A Right Perspective of Practical Values.—As used here "perspective" means placing things in their proper relations to each other; giving them their proper relative values. Some men never arrive at an appreciation of this essential element. They can never distinguish between the essential and the non-essential; between the fundamental and the ornamental. Unfortunately, some engineers have this failing in respect to practical, or business matters. They have no business judgment. They have no appreciation of values. They are the ones that bring upon the profession the criticism that its members are lacking in practical business sense. Of course, the same accusation is true of members of all other professions. But we are engaged here in self analysis and will not permit ourselves the satisfaction of hiding behind the faults of others.

Even if the engineer does not aim to be a commercial manager, but confines himself as a specialist strictly to the engineering branch of his profession, still his practice must be in harmony with the commercial conditions of his specialty.

Someone has defined engineering as a "compound of common sense and mathematics." This is a good definition to bear in mind.

A Sense of Personal Responsibility.—A general fault of the times, not restricted by any means to engineers, but one of which they are also guilty, is the lack of a feeling of responsibility on the part of the individual. It is an entirely too common a procedure to shift responsibility from one shoulder to another, and to get into the habit of looking upon all mistakes as being the other fellow's fault. More effort is frequently expended finding

reasons why one is entitled to be excused from doing his full duty or bearing the responsibility for a failure than in an honest effort to meet his obligations. The mental habit of self-justification for mistakes committed is an evidence of weakness of character.

Such a tendency is an outgrowth of a lack of discipline which is manifest in our modern institutions of all kinds—commercial, educational, and political. It, in turn, has grown out of an abuse of the principle of personal liberty. An extreme example is seen in the socialistic idea that has been advanced in many of our cities that one is not personally responsible for making an honest living, but is entitled to be supported by the community.

Responsibility is a cumulative quality. Coupled with discipline it makes the individual responsible to his chief, and his chief responsible not only for himself but for those under him. Thus it extends from the lowest to the highest rank, no one being excused from its operation. Without it, efficient organization is impossible.

One who is lacking in this particular quality of honesty, which has here been called the sense of personal responsibility, is not likely to acquire the full confidence of his associates. Business organization makes it necessary that one in an important executive position see most of the facts regarding the work for which he is responsible through the eyes and the brains of other men—his subordinates. The subordinate, then, must be not only accurate in his observations, but honest and loyal in his mental attitude with respect to the obligations and responsibilities which rest upon him.

Present Tendencies.—A study of the present day activities of the business world shows that the place filled by engineers is rapidly enlarging. The engineering professor is passing from the period in which mere design and construction are its sole duties, into a much broader field—and the engineer's influence will broaden accordingly. He is essentially an economist, an adjuster of business relations and investments. Commissions for appraisals, valuations and public management are calling more and more for engineering services, and in turn making the engineer more of an economist and business manager.

It is gratifying to note this tendency on the part of engineers to qualify for business administration. It is also gratifying to note that the public is beginning to recognize their worth. Some notable examples have recently occurred of the public confidence in the ability of the engineer to administer big business affairs with surer integrity and greater efficiency than can be expected through the usual political administration. The City of Dayton, Ohio, has recently created the office of City Manager, and offered Col. Goethals, Chief Engineer of the Panama Canal Commission, a salary of $25,000 a year to take the job. He declined their offer, but another engineer was appointed to the position at a salary of $12,500. The City of Ottawa has recently made a contract with Sir Alexander Binnie, the well-known English engineer, whereby it turns over to him for the remarkable fee of $400,000 the entire engineering and administrative control of the design and construction of their proposed $8,000,000 waterworks system. The point to be emphasized here is not the big fee, but the evident inference that the city recognizes the advantage of an engineering administration over a political one. Lethbridge, the first city in Western Canada to adopt the commission form of government, has just elected three commissioners, all of whom are engineers.

"A former mayor of the City of New York, in testifying before a legislative committee, made the statement that if he were to be confined in his selection of heads of departments to men who could assume their duties and be prepared at once to administer the work of the several departments efficiently without devoting a considerable part of their term of office to learning what was expected of them, he would be obliged in a large proportion of cases to name civil engineers."*

Public sentiment is steadily growing more favorable to the engineer in respect to his appointment to responsible public positions. This sentiment is being aided by the various engineering organizations of the country, especially by the American Institute of Consulting Engineers, which has been conducting an active campaign along this line. Evidence of the betterment of conditions affecting the opportunities open to engineers is also seen in the great increase within recent years of the numbers of engineers holding positions of administrative and executive responsibility with railroad companies, and with other big business corporations. A few years ago engineers were not considered practical enough to fill such offices as that of business manager or president. Now, scores of them are held creditably by engineers.

Another fact bearing on this point is the vast increase in the last few years of the amount of construction work done directly under the direction of engineers instead of the old-time "practical" contractor. Notable examples are the Panama Canal and the Los Angeles Aqueduct. The prejudice which formerly existed against engineers and kept them out of the business side of construction has so far disappeared that nearly all the big contracting firms are either entirely controlled by engineers or depend largely upon engineering advice for guidance.

All these are favorable symptoms and tend to broaden the scope of the engineer's opportunities. In recognition of the demands for competent engineer-managers, some of the engineering schools, notably the Massachusetts Institute of Technology, are offering courses in engineering management to prepare engineers for executive positions. Let us hope that a healthy progress in this direction will continue and that engineers will prove themselves able by demonstration to refute the criticism that they are lacking in practical business sense.

Citizenship.—Coming now to the last of the three criticisms—that the engineer is too little interested in the welfare of the community, or of society, there is much to be said.

Modern progress is to a large extent a monument to the engineer. He, more than any other class of men, has been responsible for the marvellous advance made during the past century. Means of transportation and communication and the development of power, are the chief factors in creating modern conditions and these are largely the work of engineers. This being the case, why do engineers occupy a position of so little prominence in the conduct of public affairs? The number of engineers who have become notable for their activities and influence in the political and social affairs of their country is few, deplorably few, in comparison with the importance of the engineer's work in modern civic life.

One reason, of course, is that they are usually employed temporarily for a specific piece of work and when it is completed they move on to something else, thus ob-

---

*Extract from an address by Dr. N. P. Lewis, M.Am.Soc.C.E., on "The Engineer as a Professional Man."

taining no material footing or interest in a community. This is more generally the case than it should be. It leads to the complaint among engineers that they do not receive due praise and credit for their work. What else is to be expected when they are so quick to fade into the background and leave the lawyer and the politician not only to manage the works they create, but to mould and direct public thought.

The expenditure of public money is an important part of the administration of public affairs. It is notorious that large sums of public money are squandered on great public works because they are done in an inefficient and uneconomical way. Engineers see and recognize this more than other men. I do not mean to convey the idea that it devolves upon them to do routine professional work for the public without compensation, but a lively interest and a properly directed influence may do much to correct the evils. Their judgment should be a much more prominent factor in moulding public affairs. What is needed is a habit of mind among engineers that will cause them to take an active part in all public questions where their knowledge and experience will enable them to contribute to the common good. Let them advise the legal profession and the legislator in forming laws governing public utilities and guarding the public health. Let them become leaders in the affairs of their government and promote the highest efficiency in its work. The influence of the professional man—the man with the right professional spirit—is needed in the direction of public affairs as well as in corporate management. The professional spirit is essentially the sense of trusteeship. The professional man takes in trust the affairs of his client. It is closely akin to what I have called the sense of personal responsibility.

The great problem of the twentieth century is a social problem. The manifest tendency of the times to put more and more power into the hands of the ignorant and uneducated, while being done in the name of personal liberty, is endangering the high standards and efficiency of our institutions—a tendency towards deterioration. The engineer's training should enable him to see things as they are, to see through the shams of socialistic theories that profess to offer a cure for all the ills that society is heir to.

I close with this sentiment: "To look upon politics and public service with contempt and disgust indicates neither intelligence, wisdom, nor patriotism, but rather ingratitude and a low order of citizenship. Your country needs your very best judgment upon public questions. This is not a mere privilege, it is a duty you owe the nation in return for the benefits of citizenship."

The Scottish District of the Institution of Municipal and County Engineers have been discussing the problem of road construction, and considering in particular the question of laying down some experimental stretches with different methods of construction, so as, if possible, to obtain data showing the methods that are best suited to the climate and the traffic. Experimental road sections are to be laid down in ten different places, and in each place eight different forms of construction are to be employed contiguously. So far as possible materials obtainable in the vicinity will be used, the binding materials will be uniform, and the gradients will be practically similar. In addition, the methods of construction will be simple and cheap, and quite applicable, so far as cost is concerned, to the districts in which the experiments will be carried out. Periodical examinations of the road surfaces will be made, the wear and tear noted, and records of the climatic conditions kept.

U.S. IRON AND STEEL INDUSTRY, 1913.

THE quantity of iron ore mined in the United States in 1913 is estimated by E. P. Burchard, of the U.S. Geological Survey, to have been between 58,000,000 and 60,000,000 long tons. This estimate is based on preliminary reports from 25 of the largest iron-mining companies, which represent the principal iron-producing districts and whose combined output is about 81% of the total iron ore mined in 1912.

The average increase in output shown by these 25 companies was 8% over that for 1912, and if this increase should be maintained by all the iron companies in the United States the total output of iron ore for 1913 should reach 59,500,000 long tons. At any rate, it appears almost certain that the former high record of iron ore mined, 57,014,096 long tons in 1910, has been surpassed in 1913. The reports received for 1913 showed considerable variation in the percentage of changes in output compared with 1912, the maximum range being from a decrease of 36% to an increase of 56%. These apparently wide variations were evidently due to conditions affecting particular companies rather than to general or even local conditions of the iron-mining industry; moreover, they concerned, for the most part, the operations of companies whose production is not sufficiently great to affect largely the grand total tonnage.

In Lake Superior district, where 85% of the domestic iron ore is mined, the increase in production corresponded closely with that of the United States in general, or about 8%, thus indicating a total production for that district of about 50,000,000 long tons, compared with 46,368,878 tons in 1912. The year 1913 is therefore a record year for production and shipments in this district also. The preliminary figures indicate that the shipments of Lake Superior ore by water will exceed 49,000,000 long tons, which, together with the all-rail shipments of more than 800,000 tons, brings the figures for total shipments of Lake ore very close to the tonnage of ore mined and indicates that not much change has occurred in the stocks of ore at the mines in the Lake district. These stocks amounted at the close of 1912 to about 9,500,000 long tons of ore.

In the Birmingham district, Alabama, the production of iron ore in 1913 as indicated by the preliminary returns was about 10% greater than that for 1912. In Tennessee there was apparently a slight decrease and in North Carolina a slight increase. New Jersey and New York both showed slight increases, while Pennsylvania showed a slight decrease. In the Rocky Mountain district of Wyoming, Colorado, and New Mexico there was a slight decrease.

The types of iron ore produced commercially consist of red and specular hematite, brown ore, magnetite, and siderite, or spathic ore. Hematite constitutes about 90% of the output. Only a very small fraction of 1% of the output is siderite, the production of brown ore and magnetite together constituting nearly 10% of the total.

ELECTRIC RAILWAYS IN CANADA.

There are in operation 1,308 miles of electric railways of the first class, main track; second class, main track, 205 miles; siding and turnouts, 121 miles. Total single track, 1,724 miles. The capital involved is $122,841,946, according to a Government report. The revenue collected for the year was $23,400,250, while the working expenses for the year were $14,266,674. The additions made to the capital during the last five years approached $50,000,000.

CENTRIFUGAL PUMPING MACHINERY

ABSTRACT OF INTERESTING PAPER ON THE GENERAL CHARACTERISTICS, POSSIBLE SERVICE, METHODS OF OPERATION AND LIMITATIONS OF CENTRIFUGAL PUMPS, READ BEFORE OTTAWA BRANCH CAN. SOC. C.E., FEB. 12, 1914

By J. W. W. DRYSDALE, Jr., B.Sc.,
Director Drysdale & Co., Limited, Yoker, Glasgow, Scotland.

It is not my intention to deal in this paper with the hydraulic design of centrifugal pumps, but rather to endeavor to point out the general characteristics of these machines with reference to the best type of pump to use for a particular duty, to note the services for which these pumps are specially adapted, to give some description of the more general methods of operation, and to describe the limitations of this class of machinery in actual practice.

Characteristics of Centrifugal Pumps.—Centrifugal pumps (and under this heading are included turbine pumps) are regulated by the following general laws:

1. The quantity discharged by a pump, when running at constant speed, varies with the total head against the pump. (By "total head" we mean the head from all causes, including suction lift, delivery head, and head due to friction in the piping.) If the total head be increased (the speed being kept constant) the quantity delivered will be decreased; and conversely, if the head be reduced, a greater quantity of water will be discharged by the pump.

2. The efficiency of a pump running at constant speed varies with the output, and will reach a maximum under a certain condition of head and discharge. A pump which is running at this point is said to be giving normal output. For any given speed, there is a definite maximum possible head which the pump can overcome, and the normal output is nearly always a little below this point.

These general laws have limitations. For instance, the sides of the impeller are revolving in what is generally termed "dead water," and hence if the speed of the impeller is increased, the disc friction is increased until the amount of power absorbed in this manner becomes too large a proportion of the total power absorbed by the pump. When this occurs it is necessary to increase the number of impellers in the pump. One impeller delivers into the next and so on, the head being obtained in a number of stages.

In addition, care must be taken that "cavitation" does not occur. Cavitation may take place either on the suction side or on the delivery side of the impeller. The effect of cavitation is generally overload on the driving machine and unstable delivery by the pump, and in serious cases the pump will stop working altogether. On the suction side, cavitation is caused chiefly by the suction lift being carried beyond the practical limit. On the delivery side, it is most often met with in centrifugal pumps with guide-vanes, (i.e., in that class of pumps generally known as turbine pumps). In these pumps it is generally due to badly designed guide-vanes, or to the pump being used to deliver a quantity of water far in excess of the normal output for which the pump is designed.

Curve No. 1 gives the variation of head and quantity in a pump running at constant speed. This type of curve is generally called the "characteristic curve" of a centrifugal pump, and is the most usually adopted method of showing the performance of a pump graphically. The actual curve shown is one selected at random from a number of test curves, but for convenience we have called the point of normal output 100, so that the quantity delivered, head, efficiency, and brake horse-power for any other point of operation may be read off as a percentage.

Taking, therefore, the normal point of the curve as 100, then at 75% of the normal quantity, the head is 106% of the normal head, the efficiency is 97% of the normal efficiency and the b.h.p. is 84% of the normal b.h.p.

At 75% of the normal head, the quantity is 130% of the normal quantity, the efficiency is 85% of the normal efficiency, and the b.h.p. is 112% of the normal b.h.p.

From this curve, which may be taken as being typical of a well-designed centrifugal pump, it is seen that a good efficiency can be maintained over a wide range. Thus the capacity can be varied from 70% below normal to 120% above normal with a fall of only 5% in the normal efficiency. On looking at the b.h.p. curve, we see that the maximum possible power taken by the pump is only 17% greater than normal. This being so, it follows that a reasonably well-built motor will be capable, running at constant speed, of taking charge of any duty which the pump may be called on to perform at that speed. My firm have frequently built pumps in which there was practically no overload at all, but as a rule all that is necessary is to design the pump so that the maximum overload does not exceed about 10% to 15% or even 20%, as any motor with a good rating will stand this overload without damage.

An important point to notice in connection with centrifugal pumps (and this may also be observed from the curve) is that there is no possibility of damage to the pumps in event of the delivery valve being closed during pumping operations. Thus, on the curve shown, when the valve is closed the pressure is only 92% of the normal.

While the curve shown may be taken as being typical of a well-designed centrifugal pump, it is also possible by suitable modifications in the internal design to alter the features of this curve to suit particular requirements. Thus pumps can be built in which the variation of the quantity with head is large, and others with small variation, but pumps with large variation of quantity are susceptible to a heavier overload than those with small variation. It is not possible to combine maximum quantity variation with minimum overload, but while minimum overload can only be combined with moderate quantity variation, a very fair compromise can be effected in practice. It is often necessary to design pumps with a special characteristic to suit certain specified conditions. Thus, in the case of graving docks, the head generally varies from zero to maximum, while the dock is being pumped out, but by suitable design of the pumps the

power can be kept approximately constant throughout the operation with the motor running at constant speed. The driving motor is thus running economically during the whole period of pumping, and the size and cost of the motor reduced to a minimum.

I have confined myself in these remarks on the characteristics of centrifugal pumps chiefly to the question of constant speed operation, because in Canada most of the electric current supplied is alternating, but a few remarks on the operation of centrifugal pumps at variable speeds may not be amiss.

To illustrate these remarks I have plotted curve No. 2 from actual test results. The first point to notice is that the speed of a centrifugal pump varies as the square root of the head and as the quantity delivered. The curve marked "normal," drawn through the points of maximum efficiency at each speed, is a parabola. Similar curves, the points on which all represent equal efficiencies, can also be drawn.

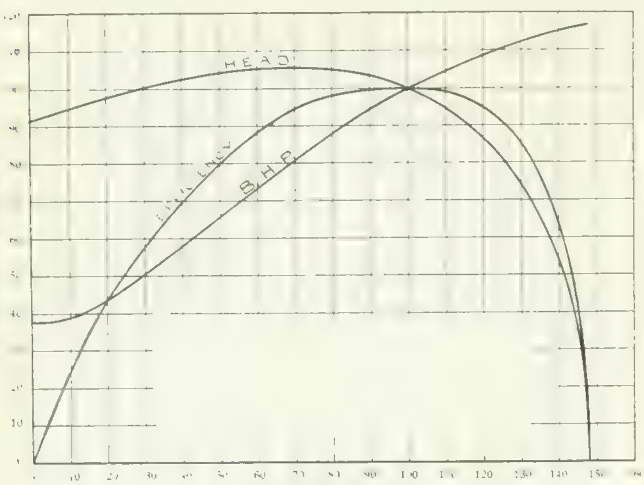

Fig. 1.—Characteristic Curve of Centrifugal Pump at Constant Speed.

Suppose a centrifugal pump is working at the point *G*, i.e., delivering 2,350 gallons per minute against a total head of 37 feet at a speed of 650 r.p.m., the efficiency being 78%. Now, suppose the speed is kept constant and the head is reduced to 30 feet, it will be seen that the quantity is increased to 2,750 gallons per minute and that the efficiency taken on the parabola has dropped to 70%. Now, suppose that instead of keeping the speed constant we reduce it till we get the head required, and we find that in doing so the quantity delivered has become reduced to 2,150 gallons per minute at the point *H*. The efficiency remains the same as it was at *G*. (In cases where the head is very greatly reduced this is qualified by the fact that the blade angles of the impeller are not quite correct for the lower speed.)

Now, suppose we are told that we must have the same quantity of water as before, but with the head reduced to 30 feet. Drawing the constant speed curves through the point *H* (i.e., the point where we had both the head and quantity reduced) and through the point *K* (i.e., the point where the head is reduced and the quantity remains the same as before) we find that we must now increase the speed by an amount, *J K*, or starting from the point *G*, the speed must be reduced by an amount *K L*.

The point *M* was where we got to by reducing the head at constant speed. The point *K* is where we get to by reducing the speed, keeping the quantity constant. It can, therefore, be seen that the most economical way to work under a varying head is to vary the speed, since the point *K* represents a better efficiency than the point *M*. Further, the additional quantity of water obtained at constant speed when the head falls, may not be desired; but if it is, then there is no object in varying the speed; should the additional quantity of water not be required, the balance of head can be made up by partial closing of the sluice valve, but the head taken up in the sluice valve represents that much wasted power.

Range of Application of Centrifugal Pumps.—Centrifugal pumps may be used under almost any conditions where it is necessary to deal with liquid or semi-liquid. There is such a wide range of uses that we will readily recognize that there must necessarily be a considerable variation in design between the various types of pump. Thus, where there is only a small percentage of gritty matter in the liquid to be dealt with, it is only necessary to make certain wearing parts of the pump easily renewable, but when the liquid contains a considerable amount of solid material of an abrasive nature, it is usually necessary to build a pump which is lined either partially or wholly in the interior. There is a good deal of divergence in the design of various makers of dredging pumps, and the designs of dredging pumps by the same maker will also vary according to the nature of the duty to be performed. Sometimes it is only necessary to line the pump at the sides, the volute being unlined, while it is often imperative to fit the whole interior of the pump with liners. There are duties where liners of the best manganese steel become worn through in a few weeks, so that it will be seen how necessary it is for a pump working under these conditions to be totally lined throughout.

Lay-out of Centrifugal Pumps.—An important point to notice in connection with the lay-out of pumping schemes is that hot or gaseous liquids should flow into the pump by gravity. When a pump is working on a suction lift it creates the vacuum necessary to overcome the suction lift. If, therefore, a liquid with temperature approaching the boiling point at atmospheric pressure has the pressure on it reduced on account of the vacuum created by the pump, the liquid will tend to vaporize, and if sufficient vapor gathers the pump will stop working. It should also be noted that the higher a place is above sea level, the less the atmospheric pressure becomes, and consequently the possible suction lift of the pump is reduced in proportion. It should also be noted that the specific gravity of a liquid or mixture does not affect the total head dealt with by a centrifugal pump impeller, but it only affects the power necessary to raise the liquid (and of course the pressure in the pump). Thus a centrifugal pump running at a given speed would raise a liquid having a specific gravity of 1.2 to exactly the same height as it would raise water of unit specific gravity, but the b.h.p. taken would be 1.2 times as great and the pressure in the pump would also be 1.2 times as great.

In connection with these remarks on the lay-out of centrifugal pumps, I am fully aware that some of the matters touched on may seem somewhat elementary to those who are familiar with this class of machinery, but as it has frequently happened that an oversight in what may seem a small and obvious item in the complete design of a pumping plant has been overlooked in the general arrangement, I feel that on this account and for the benefit of those who have not been in touch with this class of work, I am justified in elaborating these matters.

In order to make the suction lift as small as possible, centrifugal pumps should be placed as close to the water as possible. Where there is a suction lift, the pipes should be as short and direct as possible, and should always incline upwards to the pump. If this is not pos-

sible they may be horizontal, but they should never dip downwards as this may allow air pockets to be formed with consequent unsatisfactory working. I have come across cases where air pockets have been unavoidable, and it has been necessary to keep the highest point of the suction pipe in communication with a condenser or vacuum pump. As a rule it is not advisable to exceed a suction life of 20 ft. including friction, but where it is necessary to go beyond this, the suction pipe line should be tested to a pressure of 30 lbs. per inch and should be absolutely tight under this pressure. It should be remembered that the effect of air in a centrifugal pump is to reduce the quantity of water delivered.

Suppose a volume of air, Vo, obtains access to the suction pipe, then at a pressure P this volume becomes

$V = Vo \dfrac{Po}{P}$ where Po is the pressure when volume is Vo. As the orifice in the pump is fixed, then when working at constant speed, if solid water is being dealt with, the volume delivered against a given external resistance has a given value, but if air is also present then the volume is reduced by V (the volume of air at the given point of minimum pressure). It follows, also, that as the characteristic is developed from zero quantity to maximum quantity the vacuum will increase so that the result generally is a reduction in the equivalent orifice due to the greater expansion at higher vacuum and increased air quantity. The effect is shown graphically on curve No. 3 and it can be seen how serious this trouble becomes at the larger quantities. The ultimate result of excessive air leakage is that the water column becomes broken on the suction side and the pump will stop delivering. Where the water flows into the pump under a head, if it is impossible to avoid loops or pockets, it is advisable to place an air cock at the highest point of the pocket to release the accumulated air.

The speed of water in delivery pipes should not exceed about 500 ft. per minute unless the pipe line is very short. It frequently happens that the output of a centrifugal pump with a certain size of delivery or suction branch is much too great for the pipes to be made the same size as the branches. In such cases it is advisable to fit taper pipes next the pump branches. The length to make these taper pipes to give the best results is given by the formula

$$\text{Length} = \frac{D - d}{2 \times 0.12}, \text{ approximately equal to } 4\,(D - d)$$

Where D = diam. of large end in inches

d = diam. of small end in inches

0.12 = constant representing tan $6^\circ\ 50'$.

(This angle of about 7° has been found by experiment to be about the best for water.)

Where centrifugal pumps are working on a suction lift it is necessary to charge them (and the suction pipe) with water. There are two methods of doing this:

(1) To withdraw the air from the pump casing and suction pipe, thus causing a vacuum which becomes filled with water from the suction tank or sump.

(2) To place a foot-valve at the bottom of the suction pipe and fill the pump and suction pipe with water.

As examples of the first method we have the steam ejector, compressed air ejector, and ejector operated by water. Any of these ejectors may be used according to the facilities offered. The ejector is generally placed on the top of the pump casing and when the pump and suction pipe have become filled with water the steam, compressed air, or pressure water is shut off and the centrifugal pump started up. The air in the suction pipe and pump may also be withdrawn by means of a vacuum pump. This is operated by hand or power according to size. In the smaller sizes of centrifugal pump, the air pump is often attached to the pump bedplate but in the larger sizes where power is required it is generally made an independent unit. In the case of intermediate sizes, it is sometimes driven from the centrifugal pump spindle by means of a belt or chain.

In the second method, the foot-valve should be placed sufficiently far below the surface of the water to ensure that "solid" water is obtained under all conditions of pumping. Where pumps are charged by means of a foot-valve there is another point which it is important to notice. Suppose a pump is running and the driving motor stops suddenly, due to the blowing out of a fuse or from some other cause, then if the pump is fitted with a foot-valve the column of water in the delivery pipe drops down and closes the valve. It can be readily understood that in cases where the static head is considerable, the pressure caused by this column of water being suddenly brought to rest may become very great, and as the pump casing is generally weaker than the pipes on account of its larger diameter, there is great danger of the pump being burst and destroyed. It is, therefore, necessary where the static head (including suction) is greater than 30 or 40 feet, to fit a check valve on the delivery side of the pump. It is often handy to fit this valve with a by-pass which can be opened for the purpose of charging the pump.

The design of the foot-valve selected should be such that the flap can be easily raised by the centrifugal pump, as if the flap is too heavy the valve does not come fully open and the pump will not deliver its full quantity. In fact, cases have occurred where the centrifugal pump could not open the valve at all on account of the excessive weight of the flap. Foot-valves should always be chosen so as to give a clear area through them at least equal to the area of the suction pipe. In large sizes foot-valves, where used, are generally of the multiple flap type, though it is usual to employ one of the other methods of charging for large centrifugal pumps. Strainers are nearly always fitted to the suction pipes, and these should always be of large area.

Some Types of Centrifugal Pumps.—Centrifugal pumps may be broadly divided into three different classes, according to the head to be pumped against, and I shall give some illustrations showing variations of these classes.

Class I.—Ordinary centrifugal pumps for heads up to about 150 feet.

Class II.—Twin series centrifugal pumps for heads up to about 300 feet.

Class III.—Turbine pumps, i.e., centrifugal pumps having fixed guide blades in the pump casing and suitable for pumping up to the greatest heads.

In cases where the suction lift would be too great for the pump if placed on the ground level, or where on account of the expense of excavating a larger well, or where on account of risk of flooding it would not be advisable to place the motor down along with the pump, vertical spindle pumps are adopted. Thus, where sewage has to be pumped, the liquid should flow into the pump by gravity, as gas is given off more freely in a partial vacuum, such as occurs in a pump working with a suction lift. In these cases the motor is kept on ground level and the pump spindle is connected to the motor spindle by means of vertical shaft fitted with suitable intermediate

guide bearings. The weight of the motor spindle and armature is taken by the motor thrust bearing, and a common way to support the vertical shaft is by means of a thrust bearing contained in the cast iron steel supporting the motor. A flexible coupling is generally fitted between the motor spindle and the vertical shaft and sometimes also between the vertical shaft and the pump spindle. Where this is done it is necessary for the pump to be provided with a bearing to take the weight of the pump spindle and impeller, but where the lower flexible coupling is discarded and solid coupling fitted, the weight of the rotating parts of the pump is taken by the thrust bearing in the motor stool.

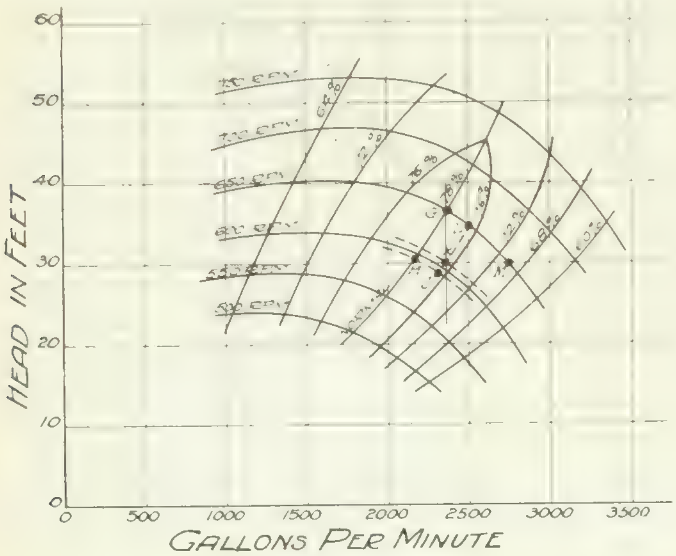

Fig. 2.

In cases where there is a very considerable rise and fall in the level of the suction water, say, greater than 20 to 25 feet, where there is a difficulty in charging the pump, or where for the sake of convenience it is advantageous to do so, the vertical spindle pump may be totally submerged. In such cases the pump is fitted with bearings of lignum vitae which are lubricated by the water, and any of the intermediate bearings which are likely to become submerged are also fitted with lignum vitae and arranged with a water service for use when these bearings are not submerged. With submerged pumps, the lower flexible coupling is done away with.

With all vertical spindle pumps, it is most important that the foundations and floor are rigid so as to prevent any possibility of relative movement between the pump and the motor. It is, of course, essential that the shafting be properly aligned. As my firm have built vertical spindle pumps having shafts up to eighty feet long it can be readily understood that there is a considerable range for pumps of this type.

Then, there is also what is termed a "multi-rotor" pump. One of these pumps recently built had six impellers all on the same shaft. When driven by an exhaust turbine at a speed of 2,500 r.p.m. it delivered 8,000 gallons per minute on a total head of 25 feet. Each of the six impellers passes its share of the water against 25 feet head, the water being split up in this manner to enable a high speed to be obtained on low head with a large quantity of water, thus making the turbine drive practicable. The pump casing is horizontally divided so that the whole of the inside of the pump can be inspected by lifting off the top half. Special diffuser pipes are fitted on the suction and delivery in order to maintain a good hydraulic efficiency.

Twin series pumps consist of two centrifugal pump casings bolted together. The first pump delivers into the second and thus for a given speed double the pressure is obtained from a twin series pump as compared with a single pump. In some cases, it is found more convenient to have a motor between two single pumps, one at each end of the bedplate, and by a suitable arrangement of piping and valves, the pumps can be put either in series or in parallel. This is an excellent arrangement where it is desired to have pumps suitable for either domestic or fire service as required.

The pumping plant supplied for the City of Edmonton, Alberta, is an example of twin series pumps. There are two sets of twin series pumps, each driven by an auto-synchronous motor of 850 b.h.p. at 900 r.p.m. Each pump, when working by itself, gives an output for domestic purposes of 10,000,000 gallons per day (say, 7,000 gallons per minute) against a pressure of 110 lbs., and when the two pumps are put in series, the combined output of the plant for fire purposes is 7,000 gallons per minute against a pressure of 160 lbs. The pump casings are fitted with gunmetal liners to prevent corrosion, the pump covers are fitted with impeller bearing rings, the impellers are of phosphor bronze, and the spindles are of nickel steel fitted with gunmetal sleeves.

In ordinary centrifugal and twin series pumps it is most important that the pump volute should be properly designed in order to reduce the speed of the water after it leaves the impeller in such a manner as to get the greatest efficiency from the pump, and, of course, the impeller has to be designed so as to give the water the correct velocity (including the correct direction) both at entry and at exit. In the case of turbine pumps, the water, when it leaves the impellers, is taken charge of by fixed guide vanes. These guide vanes must not only have the correct angle for the water leaving the impeller, but they must also be of sufficient radial depth to ensure that the proper amount of velocity is converted into pressure head. If the guide ring is too short there will be a loss of efficiency due to the water not being sufficiently slowed down before passing from the vanes. If, on the other hand, the guide ring diameter is made very large, the weight of the pump (and hence the price) becomes excessive, and a compromise has to be struck, the practice varying according to the ideas of the respective manufacturers. Guide vanes are generally made of hard phosphor bronze, or some other similar material to prevent corrosion. When guide vanes become worn, the efficiency of the pump falls and as the vanes introduce an additional element of wear in the pump, where the head is not too great twin series pumps may be used with advantage since they have no guide vanes and can be made with practically as good an efficiency as the turbine pumps.

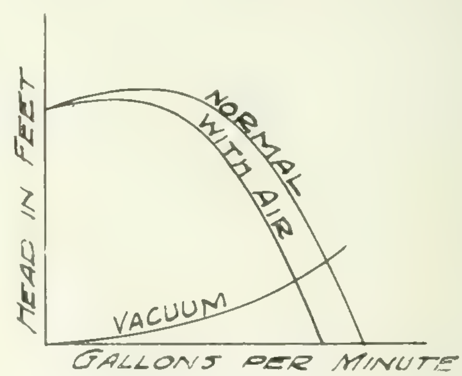

Fig. 3.

The impellers of multi-stage turbine pumps are generally of the single suction type. The most common ways of taking up the end thrust are by an automatic hydraulic balancing device or by a mechanical thrust bearing. Where the water to be pumped is clean, the hydraulic balancing device works very well, but where the water is gritty a good deal of wear takes place, and it is often found advisable to use the mechanical thrust bearing which very often takes the form of double-acting ball thrust bearing on the end of the pump shaft. Most hydraulic thrust bearings are built on the following lines: A disc which may be termed the piston is attached to the pump shaft inside the casing between the impeller of the last stage and the delivery gland, and this piston has a small chamber behind it. On the side nearest the impeller the disc has a working face corresponding to a similar face on a distance piece attached to the pump casing. If the pressure in the last stage is greater than the pressure behind the piston, the faces tend to move apart and the pressures are equalized and vice versa. This automatic regulation, based on difference of pressure, can, of course, be carried out in a number of different ways, and where the water in the pump is clean it has proved very satisfactory.

An example of this type of pump is the installation at Renfrew, near Ottawa. This pump is a 12-inch one, with four impellers, and is driven by a water turbine. The pump casing is sheathed with bronze, impellers and guide vanes are of phosphor bronze, and the spindle is of nickel steel sheathed with gunmetal. Automatic hydraulic balancer is fitted. Flexible coupling is fitted between the pump shaft and the turbine shaft. Some tests taken on this pump a fortnight ago, after about 18 months' operation, show that at the required speed of 590 r.p.m., the quantity delivered is fully 10% in excess of that called for by the specification, and the head pumped against 4 lbs. higher than the guaranteed figure.

Turbine pumps driven by a compound enclosed forced lubrication engine through double helical gearing, contained in gear box, are coming into greater favor. A two-stage pump of this kind, built recently for a head of 400 feet, runs at a speed of 1,200 r.p.m. The engine runs at 400 r.p.m., the gear ratio being 1 to 3. This is interesting, as showing how a suitable pump speed may be obtained from a slow-running steam engine, or from a water turbine where low head limits the speed. Well-made double helical gears contained in gear boxes have shown themselves to be thoroughly reliable, as indicated by the increasing extent to which they are being taken up for marine propulsion, enabling the turbines and propellers respectively to be run at their most economical speeds, and well-designed gears of this type are wonderfully quiet. So far as I can judge, helical gearing for high-speed machinery does not appear to have been adopted extensively in Canada, but I have no doubt that it will find considerable favor in the future on account of its convenience and adaptability where it is difficult to work in direct-coupled pumps, and particularly in cases where, if direct-driven, the low speed of the driving motor would necessitate the supply of a large and costly pump.

The Canada Cement Company announces that, owing to the dullness of business, they have decided to close down four of their plants for the balance of the year 1914, or until further notice. The plants affected are those at Marlbank, Ont., Lakefield, Ont., Shallow Lake, Ont., and Calgary, Alta.

COAST TO COAST.

Guelph, Ont.—Last year's receipts to Guelph from the Guelph Junction Railway earnings, amounted to $42,000. compared with $34,850 in 1912

Stratford, Ont.—The annual statement of the Stratford Light and Heat Commission shows a net surplus for 1913 of $10,218.35 on the account of the civic operating plant.

Galt, Ont.—In January, the Galt hydro-electric department made 88 new installations of service. The total number of hydro power consumers in that municipality is now considerably over 1,600.

Stratford, Ont.—The report of the Perth county engineer, Mr. John Roger, for the year 1913 shows an expenditure of $25,592.63 spent in road construction, including draining; on bridges, $5,744.02; for machinery, $3,135.77; for county road superintendent and foreman, $2,133.35, making a total of $36,585.77.

Prince Rupert, B.C.—The floating drydock for the G.T.P. Railway and Steamship Company, upon which construction is commencing at Prince Rupert at a cost of $3,000,000, will have a lifting capacity of 20,000 tons, according to the plan furnished by William T. Donnelly. These also show a structure so designed that it is capable of operating in sections as a number of smaller docks.

Berlin, Ont.—The two electric pumps for the Berlin waterworks system have been installed, and are giving satisfactory service. They have a capacity of 800 gallons per minute, or 1,152,000 gallons per day, and are designed to pump against a head of 200 pounds. The pumps were manufactured in Zurich, Switzerland; and are connected with a gasoline engine to be used in case of emergency.

Vancouver, B.C.—Up to the end of 1913 the expenditure by the Greater Vancouver Joint Sewerage Commission amounted to $48,374.04, according to the statement issued by Mr. Frank Bowser, chairman of the board. It is expected that the expenditure this year will exceed a quarter of a million dollars. Also, steps are being taken to change the name of the board to the Vancouver and District Joint Drainage Board.

Victoria, B.C.—The auditor-general's report for the first six months of the current fiscal year, April 1 to September 30, was presented to the Provincial Legislature on January 22nd. The total expenditure for these months was $10,020,-102.10, and included the following as some of its items:—Works and buildings, $1,292,680.28; roads, streets, bridges, and wharves, $3,115,787.19; subsidies to steamboats, ferries, and bridges, $32,077.15.

Ottawa, Ont.—A return tabled in the Dominion House of Parliament on January 28, giving the 7th report of the Commissioners for the demarcation of the 171st Meridian, west longitude, stated that the field work in connection with the whole survey in the Yukon is practically finished. 202 monuments mark the line from the Arctic Ocean to Mount St. Elias, a distance of 645 miles, and a vista 20 feet wide has been opened through all the timber.

Montreal, Que.—The annual report of the Ottawa Electric Railway Company for the year ended December 31, 1913, shows gross earnings of $1,041,282, an increase of $106,885, and net earnings of $412,160, an increase of $12,101. During the year, a large amount has been spent in improving tracks and rolling stock as well as other properties. Four short track extensions were laid, and two sub-power stations built. The record of the company shows an increase in gross receipts from [illegible]

Winnipeg, Man.—The second annual report of the Manitoba Public Utilities Commission shows that in the fiscal year ending November 30, 1913, the commission dealt with 43 formal applications, which devolved into 63 proceedings and orders, covering almost every phase of railway, water, light and power activities and the distribution thereof, and also covering corporate rights and financing such as transfers, increase and issue of stocks. There were also 34 separate proceedings and orders instituted upon the commission's own initiative.

Swift Current, Sask.—With the completion of Swift Current's storage dam, it is believed that the town's water supply should be assured for years to come. At least 80,000,000 gallons are now conserved for city purposes, and in addition a liberal supply is reserved for the use of the C.P.R. amounting to 3,500,000 gallons daily. The supply is obtained from the Swift Current Creek, which rises in the Cypress Hills to the south, and according to Government chemists is of unsurpassed purity and of a degree of softness that makes it especially suitable for manufacturing purposes.

Chilliwack, B.C.—The new concrete sluice has been installed and is in operating order at the Chilliwack pumping plant. Considerable trouble, due to quicksands, was experienced by the contractors for the work, Love Bros. & Shirley; but the difficulty was met by the driving of piles on both sides of the Semiault river, both above and below the gates. The bed of the river below the gates is also to be lowered and widened to the depth of the bottom of the Chilliwack river. This will minimize the danger of the bed of the Semiault filling up and rendering useless the automatic gates.

Ottawa, Ont.—The main estimates of expenditures by the Dominion Government for the coming fiscal year call for a total vote of $190,735,176. When the supplementary estimates have been added to this amount, it is expected that the total will exceed considerably the total estimates of last year, $202,656,166, of which the main estimates amounted to $179,152,183. In main estimates, this year shows an increase of $11,582,993. And it is expected that, with appropriations by special statute to be added, the grand total of expenditures authorized by Parliament will reach the quarter-million mark.

Saanich, B.C.—The report of the engineering department of Saanich has been presented by Municipal Engineer Topp to the Saanich council. It shows surveys and estimates in various branches of public works making a total since March, 1913, of $507,900; while the total cost of the engineering department for the 10 months was $4,193.22, or less than 1 per cent. of the total estimates furnished. Of the various items comprising the amount for estimates, the cost of grading a number of roads totalled $131,095; the cost furnished on plans for water supply in the districts close to Saanich, totalled $77,522; and the cost for drainage schemes, $5,010.

Victoria, B.C.—The public accounts of the province of British Columbia for the fiscal year ending March 31st, 1913, were placed before the legislature on January 15th. From these it is seen that the net revenue of the province for the year was $12,510,215.08, and the net expenditure $15,412,322.02, making a balance of expenditure over revenue of $2,902,106.94. The revenue for the previous fiscal year ending March 31st, 1912, was $10,745,708.82, and the expenditure $11,189,024.35. In the way of expenditure in 1913, among the largest items are: roads, streets, bridges and wharves, $4,790,461.24; works and buildings, $2,815,648.50.

Montreal, Que.—Montreal's 1914 programme of civic development provides for the laying of about 20 miles of permanent pavements, on central streets, and a large amount of macadamizing on suburban streets, at an estimated expenditure of about $1,500,000. The paving law which charged the cost of paving on the proprietors having been repealed, the city will have to take this amount out of the loan fund, unless new legislation is made by the council in the form of a local improvement tax or some other method of financing the work. Besides permanent pavements, the programme provides for an expenditure of $1,091,000 for sidewalks, $1,700,000 for sewers and $760,000 for the aqueduct.

London, Ont.—A surplus of $36,111.14 has been reported for London's electrical department for 1913. However, Chief Engineer Gaby of the Ontario Power Commission claims that 5 per cent. of the capitalization ($439,362.49), or $21,716.32, should be deducted from this surplus for depreciation. Also, equipment consisting of switchboards, converters, transformers and other machinery, costing in the neighborhood of $30,000, is now under order by the department for the purpose of supplying the London Street Railway Company with Niagara energy. When this amount is taken out of the capital account it would appear that the department will show a deficit of some $15,000 instead of the surplus announced.

Sinclair, B.C.—There is under construction between Sinclair and Castle Mountain in British Columbia a link of 60 miles of the great circular highway which forms one of the most important features in the programme of trunk roads for that province and will afford one of the finest scenic highways for motorists on the continent. The completion of the undertaking, for which the Canadian Pacific Railway have undertaken to pay half the cost, will mean more than 500 miles of good roads always within view of the Rockies, running through Cranbrook and the Crow's Nest Pass to Calgary, thence continuing westward over the driveway to Banff recently constructed by the Dominion Government.

Kingston, Ont.—The city of Kingston has in immediate consideration an additional water main capacity. The point of difference lies in the territory to be covered. Two sections have been proposed; one scheme being to replace the old 6-inch pipe on Union Street and to obliterate the dead ends on Clergy Street, opening up a circuit of $3.225 feet of 18-inch cast-iron pipe at an approximate expenditure of $23,638.56; the other also proposing to replace the pipe on Union Street, but coupling up the dead ends on West and Bagot Streets, and replacing the uncoated Kingston foundry pipe, now installed on Union Street, representing a total distance of 5,725 feet and an approximate expenditure of $43,936.30.

Edmonton, Alta.—There were recently in Edmonton, after inspecting the country traversed by the new G.T.P. line, and particularly the section surrounding Willow River, Mr. St. John, manager of the Transcontinental Townsite Company, Mr. George Hartford of the Morning Inter-Ocean, Chicago, and Mr. W. P. Hinton, general passenger agent of the G.T.P. Company. They estimated that on the Willow River there is enough potential electric energy to supply several cities of hundreds of thousands of population each, while 12 miles away from the town are vast beds of coal of good quality, as well as other minerals. On the Willow River alone there is at least 9,000,000 feet of timber, according to Government estimates, of size and quality equalled, only by the giant trees of the coast.

Toronto, Ont.—The concrete work on the bridge being constructed over the Walmer Road Hill ravine on St. Clair Avenue West, is now complete. Mr. E. C. Law, the contractor for this portion of the work states that in the foundation over 800 white oak piles have been used, averaging a length of 45 feet each; that about 6,000 cubic yards of concrete were necessary for the monolithic piers; and that the total weight of material used in this part of the construction was about 10,000 tons. The structure consists of two abutments and 8 piers, in sections of 4 each, arched together at the top. The central span, running north and south, measures 100 feet clear between piers, while on either side is a span of 40 feet. McGregor and McIntyre, the contractors for the steel

work, are now busily engaged in placing the smaller girders in position. This work will be continued without interruption to completion.

Regina, Sask.—Steps are being taken here with the view to mining coal at Grand Coulee. Tests have been made as to the usefulness of this coal, and the scientific test by Dr. W. W. Andrews gave 10,800 British thermal units per pound of dry coal. It is believed that the deposits of coal in this vicinity are of considerable extent; and trial tests to discover the probable quantity are being made. At the point where the well was sunk, coal strata was 6 feet thick, and of increasing thickness on the north side. If the deposit is of sufficient extent to warrant mining operations the close proximity of this field to Regina will make it a valuable asset. Recently, a second seam of coal has been struck at Grand Coulee. The thickness of this seam has not yet been tested, but it is claimed that the coal is harder and of better quality than the first find. Its discovery has greatly increased the interest in Grand Coulee coal, and further drilling operations will be carried on with a view to discovering the possibilities of this second field.

Victoria, B.C.—The report of the Inner Harbor Association upon the work completed last year gives the following information:—"In the upper harbor, or basin, a large portion of the bottom has now been dredged to 20 feet deep at low water, with berths at the Canadian Puget Sound Mills of 25 feet. The large rock, about the middle of the basin, will shortly be removed. The lower harbor generally, where dredging can be done, is now 20 feet deep at low water. The rock on the western side of the entrance (off Behren's Island) has been removed; and the rocks off Shoal Point on the eastern side of the channel, have been cut back, thus widening the channel by about 60 feet and, to some extent, straightening out a very difficult turn. To the southeast of Songhees Point, the rocks have been cut back to 16 and 20 feet deep at low water. It is proposed to remove the remainder of the triangle to the railway bridge by contract work and the material utilized for reclamation purposes as originally proposed. The total amount of rock, clay, gravel and sand removed in the harbor has been about 550,000 cubic yards."

Vancouver Island, B.C.—The construction of the initial portion of the substructure of the breakwater at Ogden Point has progressed as far as is possible until more favorable weather conditions will permit of the divers laying the huge granite blocks that will form the base of the concrete structure. In the meantime, the contractors, Sir John Jackson, Limited, are concentrating their efforts upon the first 1,000 feet of the breakwater. Upon the site of this construction, in practically three weeks of the month of December, there were dumped 22,744 tons of rubble. In addition, at the core, there were dumped 9,715 tons. On the first 900 feet the stone has been levelled up to a depth of approximately 20 feet from low water mark; and arrangements have been made by Sir John Jackson, Limited, to have the first shipment of granite blocks brought down from Nelson Island early next month. This granite has been tested at the Government Laboratory and is declared to be of the most excellent quality obtainable anywhere on the coast. All the cement to be used in the construction work on the breakwater will be supplied by the Associated Cement Company, a Canadian firm, and samples of this material have been tested and approved by Government specialists for this kind of work in Canada. Also on the land side at Ogden Point, progress is shown. Already 6,394 cubic yards of rock have been excavated on the site where the giant sea-wall will extend its tentacles of stone seaward. A large area has been levelled off and several miles of steel track have been laid for the operation of the steam-engines hauling the dump-cars to the various parts of the site.

CONCRETE ROAD BUILDING CONVENTION—PROGRAMME.

The following is the programme of the National Conference on Concrete Road Building, which is being held on Thursday, Friday and Saturday of this week at the Auditorium Hotel, Chicago. Professor W. F. M. Goss, dean of the University of Illinois, School of Engineering, is chairman.

Thursday afternoon session, W. F. M. Goss presiding.

Address—"The National Conference on Concrete Road Building." W. F. M. Goss, dean, College of Engineering, University of Illinois, Urbana, Ill.

Address—"Financing Permanent Roads." S. E. Bradt, secretary, Illinois State Highway Commission, Springfield, Ill.

Address—"Can a Rural Community Afford Permanent Roads?" Oliver Dunlap, president, Iowa State Supervisors' Association, chairman, Board of Supervisors, Washington County, Iowa.

Address—"The Concrete Road System of Wayne County, Michigan." Edward N. Hines, chairman Board of County Road Commissioners, Wayne County, Michigan.

Friday morning session, A. N. Johnson presiding.

Address—"Development of Concrete Roads in the United States." Henry C. Shirley, chief engineer, Maryland State Roads Commission, Baltimore, Md.

Reports of committees:—

I.—"Contraction and Expansion of Concrete Roads." Chairman, R. J. Wig, Bureau of Standards, Department of Commerce, Washington, D.C.; N. H. Tunnicliff, civil engineer, Davenport, Iowa; W. A. McIntyre, engineer, Association of American Portland Cement Manufacturers, Philadelphia, Pa.

II.—"Joints for Concrete Roads." Chairman, W. K. Hatt, professor in charge, School of Civil Engineering, Purdue University, Lafayette, Ind.; George W. Cooley, state engineer, St. Paul, Minn.; R. J. Wig, Bureau of Standards, Department of Commerce, Washington, D.C.

III.—"Methods and Cost of Repairing and Maintaining Concrete Roads." Chairman, Edward N. Hines, chairman, Board of County Road Commissioners, Wayne County, Detroit, Mich.; J. S. McCullough, city engineer, Fond du Lac, Wis.; F. P. Wilson, city engineer, Mason City, Iowa.

IV.—"Preparation and Treatment of Sub-Grade for Concrete Roads." Chairman, Ira O. Baker, professor of civil engineering, University of Illinois, Urbana, Ill.; A. R. Hirst, state highway engineer, Madison, Wis.; A. N. Johnson, state highway engineer, Springfield, Ill.

V.—"Reinforcement of Concrete Roads." Chairman, Thomas H. McDonald, state highway engineer, Ames, Iowa; Henry E. Riggs, professor of civil engineering, University of Michigan, Ann Arbor, Mich.; Richard L. Humphrey, president, American Concrete Institute, Philadelphia, Pa.

Friday afternoon session Ira O. Baker presiding.

Address—"Experiments with Concrete for Roads Conducted by the United States Office of Public Works." Logan Waller Page, director, United States Office of Public Roads, Washington, D.C.

Reports of committees:—

VI.—"Aggregates for Concrete Roads." Chairman, Sanford E. Thompson, consulting engineer, Newton Highlands, Mass.; A. N. Talbot, president, American Society for Testing Materials, Urbana, Ill.; W. M. Kinney, assistant engineer, Universal Portland Cement Company, Pittsburg, Pa.

VII.—"Shoulders for Concrete Roads." Chairman, Maj. W. W. Crosby, Baltimore, Md.; C. A. Kingsley, state highway engineer, Little Rock, Ark.; John H. Mullen, secretary, Minnesota Roadmakers' Association, St. Paul, Minn.

VIII.—"Bituminous Surfaces for Concrete Roads." Chairman, E. J. Mehren, editor-in-chief, Engineering Record, New York City, Henry G. Shirley, chief engineer, State Roads Commission, Baltimore, Md.; James R. Marker, state highway commissioner, Columbus, Ohio.

IX.—"Finishing and Curing Concrete Road Surfaces." Chairman, F. E. Turneaure, dean, College of Engineering, University of Wisconsin, Madison, Wis.; H. J. Kuelling, president, Wisconsin Highway Commissioners' Association, Milwaukee, Wis.; E. D. Boyer, engineer, the Atlas Portland Cement Company, New York City.

X.—"Economic Methods of Handling and Hauling Materials for Concrete Roads." Chairman, Halbert P. Gillette, editor-in-chief, Engineering and Contracting, Chicago; Donald D. Price, state engineer, Lincoln, Neb.; Percy H. Wilson, secretary, Association of American Portland Cement Manufacturers, Philadelphia, Pa.

Saturday morning session W. F. M. Goss presiding.

Address—"Concrete Road Construction by the Ohio State Highway Department." James R. Marker, state highway commissioner, Columbus, Ohio.

Reports of committees:—

XI.—"Mixing and Placing Materials for Concrete Roads." Chairman, Paul D. Sargent, chief engineer, State Highway Commission, Augusta, Maine; Arthur H. Blanchard, professor of highway engineering, Columbia University, New York City; C. W. Boynton, inspecting engineer, Universal Portland Cement Company, Chicago.

XII.—"Cost of Constructing Concrete Roads." Chairman, A. N. Johnson, state highway engineer, Springfield, Ill.; Joseph Hyde Pratt, state engineer, Chapel Hill, N.C.; Albert Reichmann, president, Western Society of Engineers, Chicago.

XIII.—"Thickness, Crown and Grades for Concrete Roads." Chairman, Leonard C. Smith, in charge of roads and pavements, University of Wisconsin, Madison, Wis.; Earle R. Whitmore, city engineer, Port Huron, Mich.; T. R. Agg, assistant professor in civil engineering, Iowa State College, Ames, Iowa.

XIV.—"Proportion and Consistency of Materials for Concrete Roads." Chairman, C. U. Bowley, city engineer, Sheboygan, Wis.; C. C. Widener, city engineer, Bozeman, Mont.; George A. Dingman, engineer, Board of County Road Commissioners, Wayne County, Detroit, Mich.

XV.—"Form of Specifications for Concrete Roads." Chairman, A. Marston, dean and director, Division of Engineering, Iowa State College, Ames, Iowa; A. N. Talbot, president, American Society for Testing Materials, Urbana, Ill.; George W. Cooley, state engineer, St. Paul, Minn.

PERSONAL.

A. J. MacLEAN, formerly one of the commissioners of Edmonton, was appointed Assistant City Engineer of that city and assumed his duties on February 2nd.

D. W. JOHNSON has been appointed engineer for the municipality of Saanich, B.C. For the past five years he has acted in a similar capacity at Point Grey, B.C.

J. M. BEGG, assistant city engineer, in charge of sewers, read a paper before the Edmonton Engineering Society on the 5th inst., entitled "The Tunnel Sewers of Edmonton."

J. W. W. DRYSDALE, Jr., B.Sc., director of Drysdale and Co., Limited, of Yoker, Glasgow, Scotland, manufacturers of centrifugal pumps, is in Canada on a four weeks' business trip.

W. A. McLEAN, Provincial Engineer of Highways for Ontario, and a member of the Public Roads and Highways Commission, has been elected president of the American Road Builders' Association.

J. V. MIMMO, division engineer, C.P.R., between Boston Bar and Lytton, B.C., read a paper before the Vancouver branch of the Canadian Society of Civil Engineers, on February 3rd, on railway construction work in British Columbia.

T. H. KETTLE, until recently in the employ of the Toronto Power Company, as manager of the Transportation Department, left for Minneapolis on February 1st to take a position as Assistant Sales Manager for the Minneapolis General Electric Company.

R. G. G. OMMANNEY, a member of the engineering staff of the Canadian Pacific Railway, has recently been appointed engineer to Sir Thos. Shaughnessy, president of the road. Under this new appointment Mr. Ommanney will devote his time to special work.

A. J. McPHERSON, for several years chairman of the Highway Commission of Saskatchewan, has been appointed to the chairmanship of the Government Finance Commission of that province. Mr. McPherson graduated in 1893 from the School of Practical Science, Toronto. F. J. ROBINSON of Regina, formerly Deputy Minister of Public Works, succeeds him as chairman of the Highway Commission.

W. E. WOODHOUSE has been appointed Superintendent of Motive Power for the eastern division of the Canadian Pacific Railway, his headquarters to be in Montreal. Mr. Woodhouse has been in the employ of the company for 22 years, spending a greater portion of that time in British Columbia, coming back to Winnipeg in 1906, where for the past four years he has been Assistant Superintendent of Motive Power of the western lines.

CANADIAN GOVERNMENT EXHIBIT AT SAN FRANCISCO IN 1915.

The final plans for the Canadian pavilion at the Panama-Pacific International Exposition, to be held in San Francisco in 1915, were accepted January 21, and the process of actual construction has begun, under the supervision of Colonel William Hutchison, of Ottawa, the Canadian Exhibition Commissioner. Colonel Hutchison arrived in San Francisco January 14 to inaugurate the work upon the building, preparatory to the arrival of the Canadian exhibit, part of which is now en route. He was joined here by George Freeman, the London architect, who is designer of the building, and his staff.

The pavilion, which will cost approximately $300,000 will be the largest exposition building ever erected by the Canadian Government. It will be 340 feet long, 240 feet wide and 50 feet high. The whole sum expended upon the building and its contents will amount to $600,000 or more.

"THE ST. LAWRENCE RIVER BRIDGE."

At the regular monthly meeting of the Canadian Society of Civil Engineers held in Montreal on Thursday, February 5th, a paper was read on the St. Lawrence River Bridge by Mr. P. B. Motley, M.Can.Soc.C.E., Engineer of Bridges for the C.P.R. Mr. Motley presented some interesting details concerning the method in which the old C.P.R. bridge over the St. Lawrence River at Lachine, P.Q., erected as a single track structure in 1885, has, in the last two years, practically undergone complete reconstruction as a double track without interference to traffic during operations.

The plan adopted was to build two independent single track bridges, removing the old bridge in sections, and transferring the traffic from side to side during the operations.

While this was being done an average of 18 trains a day passed over the bridge during working hours.

The work was accomplished by cantilevering spans from the piers supporting the old bridge, by the sinking of pneumatic caissons under the direction of the Foundation Company, by employing floating barges, and transferring traffic from the old to the new spans as the latter were completed.

CALGARY BRANCH CAN. SOC. C.E.

Some very interesting meetings have been held by the Calgary branch Canadian Society of Civil Engineers since its inception last summer. These meetings usually take the form of a 6 o'clock dinner with an address and discussion following. Mr. J. S. Dennis, M.Can.Soc.C.E., assistant to the president of the Canadian Pacific Railway Co., gave an interesting address to the meeting held on December 29th. His subject was "Early Surveys and Surveyors of Western Canada." Upon a similar event on January 9th, Mr. Geo. W. Craig, M.Am.Soc.C.E., city engineer of Calgary, read a paper on "Modern Pavements." On January 23rd, Mr. Sam. G. Porter, B.A., B.S., M.Am.Soc.C.E., irrigation inspecting engineer for the Dominion Government, read the paper "The Civil Engineer and his Relation to Society," which appears elsewhere in this issue. On February 6th, Mr. H. A. Moore, M.Can.Soc.C.E., and general manager of the Calgary Power Co., addressed the meeting, describing the company's new power plant at Kananaskis Falls on Bow River.

"Irrigation Engineering" is the subject of an address to be delivered at the February 20th meeting by Mr. W. D. Hays, M.Am.Soc.C.E., chief engineer of the Southern Alberta Land Co. at Medicine Hat. At later dates, not as yet definitely decided upon, the speakers will be Mr. F. H. Peters, A.M.Can.Soc.C.E., Commissioner of Irrigation for the Dominion Government; Mr. H. B. Muckleston, M.Can.Soc.C.E., assistant chief engineer, Department of Natural Resources Canadian Pacific Railway; and Mr. H. J. Duffield, B.E., M.I.C.E.

These dinners are held fortnightly and are being largely attended by the members of the Canadian Society resident in Calgary and vicinity. Mr. P. M. Sauder, P.O. Drawer "V," Calgary, is secretary-treasurer of the branch.

TORONTO BRANCH CAN. SOC. C.E.

The local branch of the Canadian Society of Civil Engineers held a luncheon on Wednesday, February 11th, at which a good representation of the members were present. A short address was given by Prof. C. R. Young, Department of Structural Engineering, University of Toronto, who spoke concerning the library which the Society possesses, making a number of apt suggestions respecting its enlargement and concerning ways in which it might be made of more service to the members. In addition to its monthly meetings the branch contemplates holding a monthly luncheon of this nature during February, March and April. The secretary is John S. Galbraith, 57 Prince Arthur Avenue, Toronto.

CHICAGO CEMENT SHOW.

The Seventh Chicago Cement Show begins on February 12th and will continue to February 21st. During this period the following organizations are also convening in Chicago:—American Concrete Institute, National Builders' Supply Association, Interstate Cement Tile Manufacturers' Association, Illinois Lumber and Builders' Supply Dealers' Association, Illinois Association of Municipal Contractors, National Conference on Concrete Road Building.

CANADIAN MINING INSTITUTE.

Among the papers that have already been arranged for in the programme of the annual meeting to be held in Montreal next month, are the following:—

"Mill and Metallurgical Practice at the Nipissing Mining Co., Cobalt, Ont.," by James Johnston, Cobalt, Ont.; "The Sampling of Cobalt Ores," by C. St. G. Campbell, Cobalt, Ont.; "The Veins of Cobalt District," by Arthur A. Cole, Cobalt, Ont.; "Recent Improvements in Cyanidation," by Herbert A. Megraw, New York; "Some Notes on Mining and Milling Practice at the Alaska Treadwell Mine," by H. C. Meek, South Porcupine, Ont.; "Ore Dressing Improvements," by Robert H. Richards, Boston, Mass.; "Recent Metallurgical Developments," by A. Stansfield, Montreal; "Methods of Excavation in the Mount Royal Tunnel," by S. P. Brown, Montreal; "Factors Influencing the Cost of Power for Mining Purposes," by J. M. Forbes, Montreal; "High Carbon Steel for Sluice Linings in Hydraulic Mining," by Howard W. Dubois, Philadelphia; "Mining in British Columbia" (illustrated by colored lantern slides), by Howard W Dubois, Philadelphia; "Scientific Management," by F. B. Gilbreth, New York; "Efficiency Engineering Applied to Mining, Quarries and Industrial Plants," by H. M. Payne, New York; "The Chisana Gold Field," by D. D. Cairnes, Ottawa; "Coal Resources of the World," by D. B. Dowling, Ottawa; "Asbestos Resources of the Thetford Area," by W. J. Woolsey. Thetford Mines, Quebec; "Safety in Coal Mines" (illustrated by moving pictures), by a representative of the H. C. Frick Coke Co., Pittsburgh.

EDUCATIONAL INVESTIGATION OF INDUSTRIAL METHODS.

A number of students taking the Chemical Engineering course at the University of Toronto, under the direction of Professors Bain and Ardagh and Mr. Rogers of the Faculty of Applied Science and Engineering, spent a week on a tour of investigation to points in Western Ontario. The party visited the plants of the Dominion Sugar Co., the Empire Refining Co., and the Canadian Glass Co., afterwards proceeding to Windsor where the works of the Canadian Felt Co. were visited. The new electrolytic alkali plant of this company at Sandwich was also inspected. The party included men of the second, third and fourth years.

COMING MEETINGS.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

NATIONAL CONFERENCE ON CONCRETE ROAD BUILDING.—Meeting will be held in Chicago, Ill., February 12th to 14th, 1914. Secretary, J. P. Beck, 72 W. Adams Street, Chicago, Ill.

CANADIAN MINING INSTITUTE.—Sixteenth Annual Meeting to be held at Windsor Hotel, Montreal, March 4, 5 and 6th, 1914. Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

AMERICAN WATER WORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Deven, 47 Slate Street, Troy, N.Y.

CANADIAN AND INTERNATIONAL GOOD ROADS CONGRESS.—To be held in Montreal, May 18th to 23rd, 1914, Mr. G. A. McNamee, 909 New Birks Building, Montreal, General Secretary.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21250—January 26—Authorizing C.P.R. to construct sidings for Fraser, Limited, mileage 20.03, Atlantic Div. Fredericton Sub. Div., at Victoria, New Brunswick.

21251—January 23—Refusing application Corporation Village of Princeville, Que., for Order directing G.T.R. to provide and construct highway over its tracks, about 1050 ft. west of Princeville station.

21252—January 26—Authorizing C.P.R. and Algoma Central and Hudson Bay Ry. Cos. to operate trains over crossing at Hobon, Dist. Algoma, Ont., without their being brought to a stop.

21253—January 24—Relieving C.P.R. from speed limitation of 12 miles an hour on portion of Swift Current Southeasterly Branch Line, from Neville to Vanguard, mileage 27.5 to 43.6.

21254—January 26—Authorizing C.P.R. to construct Two (2) bridges, namely,—mileage 59.8, Kootenay Central Ry., over Findlay Creek, B.C., and mileage 46.62, Kootenay Central Ry., over Skookumchuck Creek, B.C.

21255—January 24—Authorizing, temporarily, City of Toronto, Ont., to operate Danforth Ave. Car Line over G.T.R. Toronto Type Foundry Spur, until June 1st, 1914, pending installation of half-interlocking plant at said crossing.

21256—January 24—Authorizing C.P.R. to construct bridge over Dutch Creek at mileage 75.6 of Kootenay Central Ry., British Columbia.

21257—January 27—Authorizing G.T.R. to construct extension of siding into premises of S. L. Lambert, on Block Y, east side of Burger Street, town of Welland, Ont.

21258—January 24—Extending, until May 1st, 1914, time within which G.T.R. is required to install gates to cover all tracks and sidings as well as main tracks at crossing of the first highway east of Clarkson Station, Ontario.

21259—January 28—Granting leave, temporarily and until further Order of the Board, to city of Montreal, Que., to construct and lay steel water pipe beneath main track and siding of C.P.R. Co.'s Lachine Canal South Bank Branch, subject to certain conditions.

21260—January 28—Authorizing city of Montreal, temporarily and until further Order of Board, to construct and lay 8 feet diameter steel water pipe beneath, along and across right of way of G.T.R. on part Lot 3410, Cadastral plan of Municipality of parish of Montreal, subject to certain conditions.

21261—January 22—Extending, until June 1st, 1914, time within which Cumberland Ry. and Coal Co. equip cars with automatic couplers and air breaks.

21262—January 28—Granting leave to Ottawa Electric Co. to erect, place and maintain wires across track of C.P.R., on road north of Hurdman's Bridge, at mileage 6.64 from Sussex Street Station, Ontario.

21263—January 28—Extending, until May 31st, 1914, time within which C.P.R. complete siding for McCormick Manufacturing Co., Limited, London, Ont., authorized under Order No. 20710.

21264—January 28—Approving plan "A," numbered 52969, showing bridge No. 94.4 on Toronto Subdivision of C.P.R.

21265—January 29—Authorizing the C.L.O. and W. Ry. to construct its line of railway at grade across Front Street, in the city of Belleville, Ont.

21266—January 24—Approving revised location of C.N.O.R. at Grand Lake, Tp. Barron, Dist. of Nipissing, Ont., mileage 126.37 to mileage 129.94 from Ottawa.

21267—January 28—Relieving for the present, the C.P.R. from providing further protection at the crossing of the first highway east of Shebo Station between Secs. 9 and 10, W. 3 M., Sask., at mileage 67.9 on said railway.

21268—January 28—Authorizing the N. St. Catharines and Toronto Ry. Co. and the G.T.R. to operate their cars and trains over Welland Avenue, St. Catharines, Ont., without their first being brought to a stop.

21269—January 28—Postponing the effective dates of the Special Commodity Tariff, C.R.C., No. 217, and the Joint Freight Tariff, C.R.C. No. 221, of the Temiscouata Ry. Co. increasing the rates on pulpwood in carloads and published to become effective on the 1st and 24th days of January, 1914, respectively, until the 15th day of August, 1914; and rescinding Order No. 21105, dated December 23rd, 1913.

21270—January 30—Authorizing the city of Brantford to excavate a new channel across the island immediately below the Homedale District where the L.E. and N. Ry. has built its embankment across old channel.

General Order No. 119—January 31—Ordering that whenever a railway company subject to jurisdiction of Board, intends to remove a regular station agent, it shall first notify the local municipality or Board of Trade of its intention to apply to the Board for and Order permitting such removal.

21271—January 29—Authorizing the C.N.R. to construct its line of railway across and divert public road between Secs. 5 and 6, Tp. 41, Rge. 18, W. 4 M.

21272—January 29—Relieving the Que., Montreal and Southern Ry. from maintaining, for the present, a watchman at the Chemin de Lac Crossing, in the village of Bucherville, Que.

21273—January 29—Rescinding Order No. 21155, which required the C.P.R. to stop its train No. 33 at Claremont on flag for a period of three months from date of Order, December 31, 1913.

21274—January 24—Authorizing the G.T.P. to construct its main line of railway across the Government road at mileages 213 and 214, Cariboo District, B.C.

21275—January 30—Authorizing the G.T.P. Branch Lines Co. and the C.P.R. to operate their trains over the crossing of the C.P.R. Co.'s Moose-Jaw-Lacombe Branch at Druid, Sec. 6, Tp. 33, Rge. 20, W.3 M., without first bringing trains to a stop.

21276—January 29—Amending Order No. 20937, December 1st, 1913, by striking out the figures "10" after the word "Block" where they occur in the recital and operative parts of the Order, and substituting therefore the figures "16."

21277—January 28—Approving revised location of G.T.P. Railway from the east boundary of the N.E. ¼ of Sec. 25, Tp. 53, Rge. 17, to the east boundary of the E.E ¼ of Sec. 22, Tp. 53, Rge. 17, W. 5 M., Alta., from mileage 3.14 to mileage 5.88.

21278—January 28—Authorizing the C.P.R. to construct, maintain and operate branch line of railway or spur for the Boyd Pressed Brick Syndicate from a point on C.P.R. main line, Ont. Div., London Subdivision, at mileage 34.5, in Lot 3, Con. 7, Tp. Nassagawaya, Ont.

21279—January 29—Authorizing the C.P.R. to open for the carriage of traffic portion of its double track from Islington to Guelph Junction, mileage 9.98 to mileage 39.86, Ont.

21280—January 29—Authorizing the C.P.R. to change the grade of its main line of railway, Ont. Div., Havelock Subdivision, across road allowance between Lots 20 and 21, Con. 3, Tp. Bathurst, Co. Lanark, Ont., and to change the grade of present grade crossing at mileage 15.44 on said main line.

21281—January 30—Approving plan No. 55085-2, dated November 27th, 1913, showing proposed crossings over tracks of G.T.R. adjoining Front Street, Toronto, Ont.

21282—January 29—Authorizing the C.P.R. to construct, maintain and operate branch line of railway or spur for the Canmore Coal Company, Limited, Canmore, Alta., from a point on existing spur in the S.E. ¼ Sec. 29, Tp. 2, Rge. 10, W. 4 M., at Canmore, Alta.

A weekly paper for engineers and engineering-contractors

MODERN CRANE EQUIPMENT

DESCRIPTION OF UP-TO-DATE APPARATUS FOR LOADING AND UNLOADING OF MATERIAL AND SUPPLIES WHEN SPEED OF OPERATION IS A VITAL FACTOR.

By C. F. KRUMBIEGEL,
Resident Engineer, Montreal, for Deutsche Maschinenfabrik, A.G., of Germany.

THE loading and unloading of material in bulk, such as coal, ore, slag, sand, gravel and the like is a matter of serious expense and consequently of great importance to mines, dealers, contractors, consumers, etc. There is no doubt that in many cases this matter is not given due attention and that the material is still handled in an out-of-date way by unnecessarily expensive labor from ships to cars or storage or from cars to storage or vice versa. One important consideration in this connection is the question of avoiding delays in despatch of vessels and cars and the consequent demurrage on same, as by modern methods a saving of days or weeks can usually be effected.

Fig. 1.—Loading Towers for Handling Large Quantities.

It is a proven fact that modern handling plant will in most cases pay for its first cost in a very short period by the saving in labor, demurrage and risk of accident. Besides these direct advantages there is the fact that such modern handling plants minimize any impairment in the material in the course of conveyance, especially in the case of coal, which, when handled by out-of-date methods, may be crushed and deteriorate in quality. Also, the trend of business and trade will always go to well-equipped plants, i.e., plants with the most favorable conditions for quick service and low prices. These loading and unloading equipments vary in their type and construction according to the purposes they are to be used for.

If the goods are simply to be loaded from boat into cars or vice versa, a slewing crane with grab bucket will be the correct equipment, especially if the boats are not too large or fitted with high masts. These cranes may be stationary or travelling, and driven by steam, as shown in Fig. 3, or by electricity where current can be easily supplied by wire or by a third rail. If it is necessary to clear one or more railroad tracks, the crane can be placed on a full or semi-portal and the jib can also be built to raise in order to clear the masts of the boats. (Fig. 4).

Fig. 2.—Travelling Slewing Crane Running on Bridge Girders.

The capacity of such slewing cranes runs from 4 to 15 tons, including weight of bucket. They may be also

used with advantage for dumping the material into boats from special buckets, which are transported from mines or sand pits to quay by special bucket cars.

Instead of slewing cranes, loading towers operated by steam or electricity are supplied where larger quantities of material are to be handled expeditiously. Nine of such loading towers, shown in Fig. 1, are used for handling iron ore in the Imperial Steel Works of Japan. The hoisting apparatus for the trolley is placed on a small rear cantilever and the very light trolley runs with high speed from boat to the tower, where the ore is dumped into hoppers and from these into cars.

Fig. 3.—Steam-Driven Slewing Crane.

Such towers can be built up to an hourly capacity of 250 tons of coal and a weighing device may be adjusted if desired. In most other cases, where the material is to be stored in piles adjoining the quay, a loading bridge, supported by rigid legs, is the usual equipment. These bridges can be stationary or travelling, and are in most cases driven by electricity. A trolley with grab bucket running either on top or between the bridge girders with high speed, can reach from a waterside cantilever to the outmost hatch of the boat. This cantilever can have the form of an apron to clear the masts of the boats, as illustrated by Fig. 5. This loading plant is built in Rotterdam and consists of 4 bridges with 160 ft. span and 90 ft. cantilever. The trolleys have a capacity of 8 tons each and are equipped with a slewing cantilever of 23 ft., which makes it possible to reach a large part of the boat as well as the storage without moving the boat or travelling the crane.

This is a much better scheme than the scewing bridges where one portal can travel somewhat ahead of the other, which can only be done at the cost of the rigidness of the whole structure. If the waterside apron is not required very large, the jib connected with the trolley can take its part and serves as further extension of a short rigid cantilever. Instead of a trolley with slewing jib, a travelling slewing crane can be supplied, running on the tops of the bridge girders. With this type the structure of the bridge can be kept lower and lighter in construction, having the same advantage of large working circle and avoiding the waterside apron for clearing the masts.

Fig. 4.—Arrangement of Crane to Clear Railroad Track and Vessels' Masts.

A bridge crane of this type is shown in Fig. 2. This crane is manufactured also with a trolley for reloading purposes. This bridge has the interesting feature that the second bridge, if needed as elongation, can be safely coupled to the main bridge in such a way that the trolley is able to run smoothly from one end to the other.

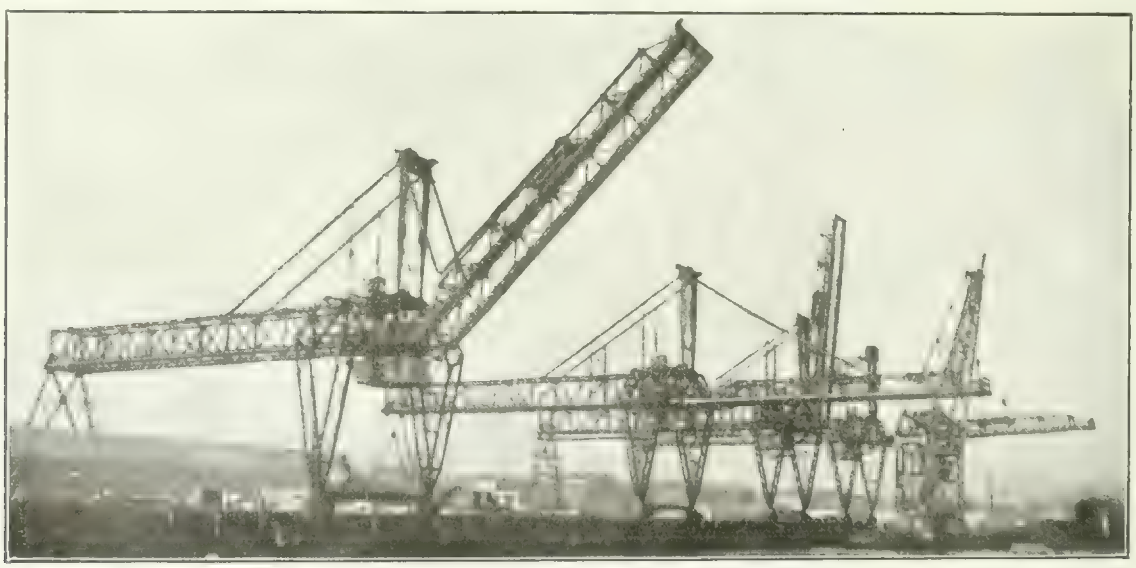

Fig. 5.—Loading Plant with Bridges of 160 ft. Span and 90 ft. Cantilever.

The writer is indebted to the Deutsche Maschinenfabrik, A.G., of Duisburg, Germany, for the photographs illustrating this article, the photographs showing a few of the many loading and unloading devices which have been built by their plants.

THE PETROLEUM INDUSTRY IN 1913.

THE feature of chief interest in connection with the foreign petroleum industry in 1913 was the active prospecting for new oil deposits, according to a statement of David T. Day, issued by the United States Geological Survey. This prospecting extended to very remote regions, including South Africa, southern Chile, Patagonia, many islands of the Pacific, China, Japan, and the East Indies.

The prospecting of most interest to the United States was that in the West Indies, Central America, and South America, on account of the approaching completion of the Panama Canal. In Venezuela American capitalists were actively prospecting in many regions, chiefly along the northern border. More than 20 field parties were engaged in exploration with a view to the selection of the most promising oil fields that might be developed, working under a provisional concession from the Venezuelan Government. These capitalists and others were also actively and successfully developing oil concessions on the adjacent island of Trinidad.

In Colombia, English, American, and Canadian oil interests were concerned with concessions for the development of large areas where, though no large oil wells have been developed, the seepages of oil and asphalt are so significant as to lead to the hope of a large addition to the supply of fuel oil. The Cowdray interests withdrew from Colombia in the later part of the year.

There was a delay in developing the oil fields of Argentina, owing apparently to the desire of the Government to retain the oil as a national monopoly.

In Chile a governmental commission examined the oil and gas indications in the Magellan region and made a favorable report.

In Ecuador the Cowdray and other interests carried on a vigorous campaign for the acquirement and development of areas showing oil indications in the interior, as well as in the region of the old wells near the coast.

Interest was shown in the possibility of finding oil in Panama, Costa Rica, Nicaragua, and Honduras, but so recently that there has not yet been time for a significant result.

In the islands of the West Indies prospecting for petroleum was active in Haiti, where a small oil well was drilled near Azua. In Cuba drilling for oil was resumed near Havana, Cardenas, and Motembo. Explorations for oil were also active in Barbados.

In Mexico development work was remarkably active considering the unsettled condition of the country. It resulted in the development of several large wells in the neighborhood of the great gusher at Potrero del Llano. Another large gusher was obtained at Los Naranjos, on the shore of Tamiahua Lagoon, which indicated a considerable addition to the total oil supply. The importance of these additions cannot well be over-estimated, for in spite of the universal judgment that the Mexican fields are potentially very great the fact remains that so far as present supply is concerned Mexico has been practically limited to two or at best three large wells and not a very large number of smaller wells of most uncertain character. Of the large wells the American (Doheny) interests owned two and the English (Pearson) one. Even with the phenomenal energy of the exploration work it was questionable whether new wells would be found promptly enough, under the peculiar Mexican conditions, to maintain present shipments, let alone supply a combined fleet of about 40 large tank steamers. The supply is now ample. As an evidence of the peculiar character of petroleum commerce, it is probable that with this additional supply the price per barrel will increase, because the greater confidence in the supply will stimulate the adoption of Mexican oil for refining and for fuel.

The 8-in. pipe line of the Mexican Eagle Oil Company (Pearson interests) was completed from Potrero del Llano to Tampico. The refinery of this company between La Barra and Tampico, north of Panuco river, is nearing completion. Among many other interesting developments in Mexico was the continued interest in the Topila oil field, near Tampico, where, in spite of many wells going to salt water, the unusually large gushers occasionally obtained have stimulated continual drilling operations.

A feature of importance for the United States was the development of a large fleet of tank steamers for coastwise and trans-Atlantic trade. Imports of Mexican oil were extended to several refining centres of the United States.

The general interest in the development of new oil fields which characterized the year 1913 extended to Alberta and Saskatchewan, in Canada. Although explorations in Saskatchewan gave either natural gas or else entirely negative results, a well 27 miles southwest of Calgary, in Alberta, struck oil of very light gravity, causing much excitement, and a large territory in that region was taken up by prospectors for oil, probably much more than will be drilled within the next year. This oil excitement extended to the region north of Edmonton, in Alberta, where on Athabaska river and its tributaries, large bodies of so-called "tar sands" have been known for many years. These "tar sands" are in places 60 feet thick where exposed on the river banks and have been traced for considerable distances from the river. Seepages of oil are reported for as much as 400 miles to the north, and many thousands of acres of land have lately been taken up from the Canadian Government for oil development at some time in the future.

Work has continued in the development of the natural gas, petroleum, and oil-bearing shales of New Brunswick.

In Russia the production of oil declined significantly in the larger fields, but meanwhile the Ural-Caspian field was actively exploited. This field is reached by steamers to the north shore of the Caspian sea. There are no wharf facilities yet, landing being made in small boats through the shoal water. About 30 miles from the shore large oil wells have already been obtained, and pipe lines are being laid to the shore where barges can be loaded and towed up Volga river without the reloading necessary for shipments from Baku. Exploration in the Ural-Caspian field north of the present oil wells has been extended over many miles and has shown that the area, while very spotted, gives promise of further development. Exploration in this field is impracticable in winter, but in summer can be prosecuted with success in spite of the great lack of water, the available supply of which is derived principally from snow scraped up in the winter and conserved in pits. The inhabitants of the region are wandering tribes living in tents. They are peaceful and disposed to aid the exploration.

In Galicia deep boring is tending to check the decline in the oil supply and the exploitation has been actively carried forward in all regions where indications have been noted in the past. It is probable that the Government of Hungary will develop the gas wells in the region of Kisarmas.

In Roumania oil production continued active in spite of the very severe fire in the Moreni field. The chief contribution to the industry by the government was the development of a pipe-line system from the producing fields to Constanza, on the Black sea.

In Japan production was greatly helped by the introduction of the rotary system of drilling.

ELECTRIC RAILWAY SYSTEMS.

AN article by Mr. C. E. Eveleth, based upon a lecture delivered by him in New York City, appears in the February number of the General Electric Review, and deals with the present magnitude of the application of electricity to transportation. The author sets down the factors to be considered in the choice, and traces the various features which influence the selection and affect the maintenance of systems. Mr. Eveleth, who is attached to the Railway and Traction Engineering Department of the General Electric Company, distinguishes between the "science" and the "art" of electric railroading in a very interesting way. His article is as follows:—

When considering the subject of electric railway systems it is well to bear in mind that only twenty-six years have passed since the first electric motors propelling street cars in Richmond startled the people by the terrifying flashes at the overhead collector and from the motor brushes. As in any radically new enterprise the pioneers were called upon to bear the brunt of development and to overcome what appeared to be almost insurmountable difficulties. The improvements made in the various elements were so rapid that soon the electric motors not only displaced horses as motive power, but also led to the extension of the field of city transportation. Then there followed the development of many thousands of miles of interurban electric lines, which have brought the outlying farms close to the cities in almost every locality east of the Mississippi river. This network is being steadily extended and will eventually cover the entire country as the density of population increases. The effect of the inter-communication so afforded is incalculable, both from an economic and sociological standpoint.

It is interesting to know, in these days when so much is heard about the increased cost of living, that such elements in our daily lives as are served by electricity have steadily decreased in cost, and to-day we ride farther for a nickel and have more electric light illumination for less money than ever before. Is it not significant to learn that the only divisions of one of our large eastern steam railroads where the net earnings per passenger car mile are holding their own are on the portions operated electrically, while on those divisions not so operated the net earnings are only a fraction of what they were seven or eight years ago and are decreasing at an alarming rate?

We sometimes ask: when will our railroads be operated electrically? In a recent lecture by Steinmetz, the statement was made that there is more aggregate horse-power in electric motors operating cars and locomotives to-day than the aggregate horse-power capacity of all of the steam passenger locomotives used for transportation in this country. Based upon this, we can fairly say that electrification is here now. The day has not yet arrived when the universal electrification of our steam railroads can be economically accomplished, but the decreasing cost of power and the lower cost of electric equipment for rolling stock is gradually extending the field where the application of electricity to transportation is justified and will eventually permit electricity to replace steam on all important railroad divisions.

At present we are using electricity to accomplish results unattainable with steam engines, notwithstanding the magnificent accomplishments which the steam engine designer has achieved with the Mallet locomotive, oil-fired boilers and the use of super-heated steam. Of all known agents, electricity is the most convenient means of distributing power and its application to transportation successfully overcomes widely different limiting conditions. On some railroad divisions about one-twentieth of the gross ton mileage is used for hauling the coal to supply the steam locomotives with fuel; on other sections, the speed on going up grade is limited by the boiler capacity of the engines. The operation in descending these same grades is frequently hazardous, owing to the possibility of the loss of air for the air brakes, or danger from overheated brake shoes and wheel tires. Applying electric locomotives to these conditions, in many instances, eliminates entirely the freight tonnage required to haul fuel. We are able to increase the speed of freight trains up grade to the maximum safe or economic limit, and by the use of regeneration we not only lessen the danger from failure of air for the brakes and the heating of tires and brake shoes, but are able to actually recover a material portion of the energy given up by a train descending a mountain and utilize this power for ascending trains. We are able to overcome the difficulties incident to bad water found in desert regions on one hand, and to more quickly transport the suburbanite on the other. Other limiting conditions which can only be met by electric traction are the elimination of smoke, the better utilization of space in city terminals by the use of differnet track levels, the elimination of round houses, turn tables and the saving of time required by steam locomotives while going for water and cleaning fires.

There are two broad divisions of the subject under consideration; one might be called the "Science of Electric Railroading," and the other the "Art of Electric Railroading."

The "Science" has to do with all the fundamental details which enter into the present development and includes the work of improvements and invention, which are necessary to broaden the field of electric traction. This includes developments in insulation, designs of generating, transmission, conversion and rolling stock equipment parts, the solution of problems of current collection, the mechanical structure of locomotives for high speeds, and the many elements which go to make up a successful and economical system of control for the electric power from the prime movers to the train wheels. There are thousands of men employed in the development of the science of electric railroading, and it is to these men that we shall be indebted for the final victories of the electrification.

The "Art" of electric railroading includes the analysis of conditions and the selection and application of the available elements to a specific problem as well as the operation and maintenance of the finished system.

It is the problem of the electrical engineer to so select and balance all the elements of power generation, transmission, and consumption in such a manner as to deliver the desired quality and quantity of transportation with the greatest reliability and the lowest cost.

As set forth, the problem seems simple, but experience has indicated that very different conclusions are reached, both as to the methods which should be applied and the anticipated results. The problem is, in fact, extremely complex; so much so that it is almost impossible to retain in mind the many elements which must be simultaneously considered to reach a justifiable conclusion. Frequently one sees results cited, which, on analysis, are found to disregard entirely elements of the greatest importance.

A better comprehension of the situation can be obtained by outlining some of the elements which must be equated. We will assume that the problem as to schedules, train capacities, grades, etc., both for the present

and future, has been accurately set forth. For conditions requiring the use of motor-car trains and locomotive operation, there are available for consideration direct current and single-phase equipments or possibly single-phase for the motor cars and split phase for the locomotives, with a further possibility of three-phase, if the problem involves the use of locomotives only. To reach the proper conclusion every element from the prime movers to the train wheels must be considered.

Power Supply.—In some sections of the country, in the Carolinas, Michigan, Montana, Washington, Oregon and California, for instance, we find networks of power distribution which range from five hundred to two or three thousand miles of transmission circuits in each system. Generally in such localities, it is more economical for a railroad to buy than to manufacture its own power, since this requires less capital expenditure, and the power companies which have the benefit of diversified load factor, can, generally, manufacture power for less cost. Where such conditions exist the frequency of the primary distribution is established by these systems. Where it is necessary for the railway to build its own power house, the question of frequency with its bearing on the power already available in the territory to be served and the demands of the particular rolling stock selected must be carefully investigated. Comparisons must be made between single-phase and three-phase power generation, due weight being given to the elements of initial cost, efficiency, power-factor and protective appliances. Some of the problems, such as the desirable size of power house units, their overload capacity, etc., is common to all unit systems.

Distribution System.—This is the simplest element in the chain and can generally be worked out on its economic merits as regards the selection of voltage, size of conductors and the character of installation to conform to the distance of transmissions and permissible line regulations for the various systems.

Secondary Distribution and Substations.—The location and capacity of substations must be considered jointly with the secondary power distributions to the trains. This involves the selection of voltage; the determination of the permissible potential drops; provisions for the mitigation of inductive interference with telephones and telegraphs for the single-phase and three-phase systems, or the consideration of the possibility of electrolytic difficulties in case of the direct current, both for normal operation and for conditions of short circuits; the selection of third rail or overhead trolley; the effect of atmospheric conditions, such as lightning, snow and sleet; examination of the reliability of the elements chosen and decisions regarding the amount of line to be incapacitated when local repairs must be made. The selection of substation apparatus will be different for each system, and will further vary with the frequency of power supply. The advisability of using transformers or auto-transformers with questions of capacity and regulation must be considered for the alternating-current systems; and with direct current, there are questions of the relative merits of motor-generator sets, rotary converters or motor converters with the determination of their normal and overload capacities and regulation. To make these different elements comparable, the selection of apparatus must be so balanced as to yield the same degree of insurance in case of the failure of individual elements or abnormal congestion of traffic, due to any cause.

Rolling Stock.—This item is by far the most important, as the proper selection of these elements is vital to the success of the system. Here we are at once confronted with the consideration of the inherent features and costs of the various kinds of apparatus available, and due consideration must be given the relative values of constant versus variable speed, features involving the starting characteristics, efficiency of motors, conversion devices, control and driving mechanisms, effects of inherent characteristics on power load factors, electrical power-factors, etc.; in addition, the desirability of regeneration and emergency braking require consideration, if mountain work is involved.

After having determined the first costs and rates of depreciation of each of the above elements, there remain two important items for consideration. The first is the analysis of power consumption, which can be carried through with reasonable accuracy for the particular conditions under consideration. The second is the problem of the determination of the operating and maintenance costs, which is more difficult. It is in these elements that the results of practice are most often lacking, and the value of an individual's judgment will depend on his general experience, and on his ability to deduce from available data information which can be applied, when properly modified, to meet the specific problem in hand.

General.—The assembly of these elements in the order of their relative merits is the problem before the engineer who is called upon to select a system for a particular application. It is not surprising that different results are reached by different investigators, due to the different weights assigned to the elements or difference in the degree of optimism towards some of the unproved features. Very often it is surprising to find how little difference there is in the initial costs of the various systems, as some of the elements tend to offset each other. For example: the high cost of single-phase rolling stock equipment frequently offsets the greater cost of direct-current substations, while the additional weight of the single-phase equipments offsets the greater conversion losses of the direct-current substations, resulting in both the cost and power consumptions of the two systems being almost identical. Consequently, with a greater quantity of rolling stock, the tendency is for the moderate voltage direct-current systems to be lowest in cost and cheapest to operate, while with few rolling stock elements the tendency is to relatively favor the higher voltage systems. For suburban electrifications a moderate direct-current voltage is generally the most economical, while for single-track infrequent service, higher voltages are desirable.

A discussion of electric railway systems would not be complete without consideration of the Standardization of Systems. There is no doubt but that standard third-rail and overhead trolley clearances are necessary to avoid serious interference with bridge girders, station platforms and various structures existing along main railway rights-of-way. About seven years ago, the Germanic countries, headed by Prussia, adopted certain arbitrary standards that all main railways should be equipped with fifteen thousand volt single-phase trolleys operated at sixteen and two-third cycles. At that time there was no experience available to justify such a selection, but it was believed by those in power to be desirable to have all efforts expended in one direction, and, furthermore, it was deemed necessary for military reasons. Since then, it has developed that the limitations imposed are very adverse to economical motor car operation, that inductive interference with telephones and telegraphs under certain conditions are extremely serious, and the low frequency involves difficult mechanical problems and practically bars out forever an economical design of induction motor for certain classes of service. These limitations are rousing some dissatisfaction in Germany; the

Italian engineers have decided that three-phase is better suited to their conditions, and the majority of engineers in England, Australia, Canada, France and Russia seem to favor direct current.

In this country we have done well to avoid a limitation such as an arbitrary standard system of electrification would impose, since it leaves us free to work in every direction, whether it be single-phase, three-phase, split phase, moderate or high voltage direct current, the mercury rectifier systems, or in any other direction which may be entirely unknown to us to-day. Arbitrary standardization of a system would mean limited development or stagnation.

Electrification of railways is desirable, not only from the standpoint of superior transportation, but on account of improvement in land values and the comfort and safety of travel. Although electrification is economically justified for many conditions, there are to-day no known systems sufficiently low in cost to permit universal use of electricity for railroads, and we must, therefore, have a free hand in order to achieve the ultimate general application which we believe will come.

WATER TOWER AT ST. VITAL, MAN.

THERE has recently been erected for the Agricultural College at St. Vital, Man., a water tank with a capacity of 125,000 Imperial gallons. The structure is mounted upon a tower, the total height being 160 ft. The weight is somewhat in excess of 100 tons. The cost, including foundations, was approximately $16,000. Fig. 1 shows the tower and tank completed.

Where such a means of water supply is resorted to in climates that are subject to severe freezing in winter time the main issue to contend with in the design and construction is to arrive at some feasible means to prevent freezing. To this end it will be noted that a riser pipe has been employed. It is built of steel, 6 ft. in diameter, the idea being that the diameter is sufficiently large to permit the formation of a natural frost jacket of ice about 3 inches thick on the interior of the riser pipe, protecting the balance of the cross-section from freezing. As an added precaution a 1½-inch steam coil, to the extent of about 100 ft. was placed in the bottom of the tank for the purpose of raising the temperature of the water.

On account of the excessive range in temperature, as well as owing to the great height of this tower, a second difficulty was encountered in attaching the riser pipe to the bottom of the tank. Obviously the variation in temperature from season to season is greater in the posts of the tower than in the riser, since the riser pipe maintains a more constant temperature than the outside air. Some provision had to be made necessarily to take up the difference in expansion and contraction between the posts and the riser pipe produced in this way.

It was deemed inadvisable to use the tank bottom as an expansion joint. To get over the existing difficulty the riser pipe was equipped with an expansion joint of large diameter at the point where it enters the tank proper. In this way the builders were able to retain the hemispherical bottom tank, which is claimed to be the strongest type in use. Another important point characteristic of this form is that the very steep slope of the bottom portion of the tank allows accumulating sediment to drain into a main drum, at the same time allowing the added advantage of the large steel riser pipe.

In order to insure a minimum of sediment and dirt in the water, the 12-inch inlet, which enters the large riser pipe at its base, has been carried up a distance of about 4 ft., thus forming in the bottom of the riser the mud drum, mentioned above, for the collection of sediment, etc., which may then be drained off. The extreme bottom of the riser pipe has been equipped with a quick opening flow-off valve so that this sediment can be carried away quickly and completely and the tank cleaned without emptying the structure.

There is also a valve chamber directly underneath the large riser pipe and below the surface of the ground, in which the pipes of the sewer system are so arranged that the water may be pumped directly into this system

Fig. 1.—Tank and Tower Recently Erected at St. Vital, Manitoba.

without going through the tank, or may be pumped directly into the tank with the same inlet and outlet, using the tank as a pressure regulator, or the water may be pumped into the tank by one pipe and discharged in the mains by operating 3 valves in the valve chamber.

The Des Moines Bridge and Iron Co., Des Moines, Iowa, furnished and erected the structure.

WATERWORKS OF CANADA.

At the 5th annual meeting of the Commission of Conservation, held in Ottawa last month, it was announced by the chairman, Hon. Clifford Sifton, that a new edition of "Waterworks of Canada," by Leo G. Denis, B.Sc., Hydro-electric Engineer of the Commission, would probably be issued. The first edition had been much in demand, especially in the rapidly growing towns and cities of the west, where the necessity of installing waterworks systems was becoming more urgent year by year. The new report would bring up to date the previously published data, and would be much more extensive in its survey of existing systems as they are at present.

The 1912 edition contained a number of charts and tables, summarizing the information in the body of the work and emphasizing points of special interest, such as the growth of the principal systems, sources of supply, rates, cost, consumption, etc. This will be extended and made still more authoritative.

HIGHWAYS AND HIGHWAY SURVEYING

PRACTICAL SUGGESTIONS APPLICABLE TO PROBLEMS OF ROAD FINANCING AND ENGINEERING—OUTLINE OF SURVEY WORK, AND EXAMPLES OF ESTABLISHED METHODS.

By DANIEL J. HAUER
Construction Economist

EDUCATIONAL work among the public as to the value of good roads is about over. The humblest farmer now appreciates the fact that good roads mean better living for him and easier methods of obtaining it. The questions now before both laymen and engineers are "What to do and how to obtain better highways at a reasonable cost?"

Road Financing.—The greatest mileage of roads on the American continent consists of the unimproved dirt roads, the so-called farm roads, leading from the farm to the nearest towns and villages, or to the main travelled highways. The roads surrounding our large towns and cities can be easily improved, for it is not a difficult matter to raise the money to rebuild these highways. But it is a serious problem to obtain money enough to make passable the thousands of miles of dirt roads.

There are two methods in common use, namely, direct taxation, and the issuing of bonds. There must be a limit to direct taxation and especially in small communities; so most road enthusiasts turn to bond issues to obtain the necessary money. Bonds must be redeemed at maturity, if the credit of any province, county or town is to be maintained. This, together with the limitations set by law, must govern the issuing of bonds. Thus it becomes evident that long-term bonds should not be issued for road building and improvements. For building reservoirs, sewers, canals and other structures that last for many decades they are justifiable and economic, but for street and road work, the term of the bonds should not exceed the life of the road. Few road and street surfaces last more than a decade, so it is a mistake that will finally bring disaster to the community that sells long-term bonds for roads and streets. Many cities and counties are suffering now from this indiscretion.

The Highway Engineer a Necessity.—This and many other considerations, to be mentioned, may not seem germane to the title of this article, but nevertheless such considerations affect highway engineering and surveying, and the highway engineer must keep them in mind. It it part of his duty to guide the public, as he alone, of public men, is fitted to prevent the taxpayer and our lawmakers from making these economic blunders. This is plainly shown by the waste of money made by those communities that have not had the advice of engineers or have acted contrary to such advice.

A common blunder made in the past, and still being made, is the general belief among public officials and the general public, that any intelligent man can build and maintain roads. This one thing has been the cause of wasting many thousands of dollars. In Eastern Canada, where the writer is familiar with the conditions, he does not hesitate to say that on the common country roads, one-half of the money now being expended is being wasted due to inexperience and a lack of knowledge of road engineering and construction. Road building and maintenance is a profession, and if the taxpayers are to obtain the best possible results for their money, they must see to it that only competent men with the requisite knowledge are employed for highway work.

At present, this is the most difficult task in road construction, due to the fact that we have such road laws that prevent obtaining competent men, and even if some are placed in charge of such work, the system under which they must labor prevents them from obtaining a dollar's worth for a dollar.

Need for Revised Legislation.—Those interested in better highways must first see to it that our road laws are changed. Small towns and rural communities are not capable of looking after their own highways. They neither have the money to employ competent men nor to purchase the necessary plant to build and maintain our highways. Hand work is too expensive to be tolerated any longer on roads. The need of conserving the available money to obtain all the improvement possible is too great to allow of obsolete methods being used.

The system of small communities looking after their roads dates back to feudal times in England. Each castle and mural town was cut off from others by vast forests infested by robbers, making communication hazardous and difficult; so that each community was compelled to build and maintain its own roads. Thus the local roads were kept in fair condition, while those through the forest were nothing more than muddy tracks. As the forest highwaymen were driven out the work on the town roads was carried into the forest and these roads made passable; but the old system continued, was brought to America, and in many sections is still in vogue.

There should be no smaller unit for road building and maintenance than a county. Thus a province or state and the general government, in giving road aid, can deal with one community rather than with 50 to 100 small units.

With the road tax paid into the county treasury, each county can have an expert highway engineer and under him can be competent assistant engineers and road supervisors. The proper machinery can be purchased, or the work can be let at contract, so that the most economical methods can be used. With this system the proper field and office work can and will be done.

Engineering is essential, no matter under what system highway work is done, or whether it be new construction, reconstruction, or maintenance. Thus highway surveys must be made. Almost any surveyor can run a line, but this is not surveying. For highway work it is essential that surveys be made with judgment and that they be complete in every detail, both as to surface of the ground and sub-surface. This brings us to the real consideration of highway surveying.

Establishment of Road System.—If only a single road is to be improved the survey can be started at once, but if a system of roads for a county or province is to be devised, then before the surveys are made a tentative road system must be laid down on a map, subject to

changes that will be found expedient to make after the surveys are to be made. Money may not be available for improving the entire system at the outset, but this should not prevent preliminary work from being done; for it is evident that if a comprehensive system is devised at the start, it is possible to expend the money for years to come with a definite policy in view and to obtain the best possible highway. Slight changes in roads and in policy may be deemed expedient, as the work progresses, but changes of administration and of officials need not affect the general policy or system of highways without this office planning (to the public seemingly time and money wasted) each administration will inaugurate new schemes, change methods and money will be wasted as it has been in the past.

In laying down a system of highways there are many considerations to be kept in mind. First, should be the farming and commercial interests. It is hardly necessary to consider the automobile. Although we owe much to the automobile interests, in as much as they have wised the public to the need of good roads, and by their concerted action and labors have made better roads possible, yet build a good road and the automobilist will find it. A few miles of extra distance means little to him, and, after traversing all the roads, he will select the scenic ones for his touring and joy rides. However, in deciding upon the road surface the automobile must be kept in mind for, next to water, the rapid moving car is the greatest destroyer of road surfaces.

The Most Needful Roads.—Those roads serving the greatest number of people should be laid down first, carrying merchandise and produce from the towns and railroad stations to the farming, mining and manufacturing centres, and vice versa. The fact that such roads may be longer than the more direct routes should be ignored, for, to be of value, the roads must go to the people. It is wrong to build a road through a country rather than in it. There may not be money available at the outset to build the long system of roads, as against a short and more direct system, but this is not a valid reason against planning the system, for ultimately the money will be provided and the sooner the proper officials and public know what is needed the sooner the financial arrangements can be made. Population and valuation must be considered in this connection which precludes roads from being built on air lines through undeveloped country. These last roads are an after-consideration.

To call a system of country roads "trunk lines" is a misnomer, and frequently injures the work being done and the raising of money for roads, in the eyes of the public. A trunk line is a through road, meant for quick communication between central points. Roads should be named from the source of deriving the money to build and maintain them. Thus the various systems should be known as County Highways, Provincial or State Highways, National Highways, etc. After these systems are built to serve every hamlet and farming district, then direct routes can be selected and re-built, to be designated as trunk lines. These should embrace those roads having the heaviest traffic and, if necessary, short-cuts and new air lines should be laid out.

A further need of improving the roads that lead to the farm is the high cost of hauling produce per ton-mile, which is paid directly by the consumer, and the high cost of hauling farm supplies, which is paid indirectly by the consumer of farm products. Then, too, improved roads tend to keep the young country boy at work on the farm, which is necessary to-day, as our rural communities are being rapidly depleted of the choicest of their young manhood.

In planning a system of highways, the various roads or lines can be designated by letters and numbers and also by towns as, Highway A, Highway No. 10, Section No. 20, and the Charlotte-Mecklenburg Highway.

Engineering Staff Organization.—A tentative system of roads once devised, the work of surveys can be commenced. For this there must first be an organization that will allow thorough work to be done, but will be flexible, being able to curtail it as circumstances warrant it and being enlarged as the amount of work increases.

A chief engineer is the first requisite. He may be the commissioner of roads himself or he may be an official of such a commissioner or commission. Under him there should be an office assistant, an engineer, who remains in the office, acting for and under the direction of the chief; an office draughtsman; a filing clerk, and a stenographer. This force can be increased as the amount of work warrants it. There can be principal assistant engineers, assistants, district engineers, chief draughtsman and assistants, and other engineers and clerks. Or, with only a limited amount of work, the office assistant can do all the necessary drawing, and the filing can be done by the stenographer. It may even be possible to combine all four positions in one.

The system of roads, if too large to be looked after personally by the chief engineer, should be divided into districts and over each district should be an engineer-in-charge. If his district is large he may need an office assistant, who should be a draughtsman, and a stenographer; but for a small district, he should be able to look after this work himself. Under the district engineer should come the field parties.

If there are more than two or three field parties, assistant district engineers should be used, each man having charge of two or three parties. These district engineers and their assistants should be the resident engineers of their district, so as to be in touch at all times with their work. It is an expensive policy to have an engineer in charge of each field party. This resident engineer is not necessary as the district engineer can visit each field party several times a week, spending such time with them as is necessary to guide the work of surveys and decide on all doubtful points. A chief of each party means extra salary and expenses, and the results obtained are not commensurate with the money expended.

The transitman can be the chief of the party. Under him should be the levelman, who runs the level and, if necessary, substitutes at the transit. The level rodman completes the level party. In the transit party there should be a head and back chainman, a rodman and a stakeman. These last two can run the back rod, make stakes and hubs, drive and number them, and carry the extra equipment. The back rodman can be dispensed with if absolutely necessary, but as his wages are small and as the increased work that can be done through his help more than offsets his salary, it is the part of wisdom to employ him. With this extra man it also becomes possible to have the transitman go ahead at times to lay out the work for a mile or so, while the head chainman runs the transit and the others chain and place the stakes. The writer prefers to employ a back rodman rather than an engineer-in-charge for each field party. As previously explained, one man can look after several parties.

The Plotting of Field Notes.—It is a common practice to-day in some sections to employ a field draughtsman. This, the writer believes, is unnecessary. Notes

should be plotted in the field, rather than in the office of the chief engineer, and it is seldom necessary to employ a special draughtsman for this purpose. If notes are plotted in the field the party, seeing what is done each day, is able to work more intelligently, and to make more complete surveys. If anything is overlooked it can be taken up before the party has gotten too far ahead.

Each day the levelman, with the assistance of his rodman, should work up his field-notes and plot the profile, especially of the transit line. The cross-sections and side elevations can be plotted on rainy or stormy days. The transitman, with the assistance of the head chainman, can plot the alignment each night, and on stormy days houses can be plotted on the map and other side notes completed. It is not a great hardship on the men to do this work and they derive benefit from it, as it makes them more careful, besides learning to do much that will be the means of bettering their positions. This, too, means the saving of a field draughtsman's salary, which could be added to the pay of those already employed, or effect a clear saving.

If notes are sent to headquarters they are always slow in being plotted. The notes may be inaccurate and incomplete, and with the field parties disbanded the results may be exceedingly unsatisfactory. From notes made in the field tracings can be made and sent to headquarters. On these, new locations and grades can be placed, from which notes and blue prints can be made and sent back to the surveying parties to be used. This makes a complete organization for surveys.

Alignment.—On the actual work of surveying, the first thing to be considered is the alignment. A complete survey should be made of the present roads. This is best done by running a transit line as near the centre of the road as possible. It is a very easy matter to say to keep in the centre of the road, and it can be done with long, straight stretches, but on very crooked roads with sharp, abrupt turns, it is quite a difficult task to do, and at the same time make a fair rate of speed in the surveys. It is evident that if the road is to be re-built on exactly the same line, then it is money saved to take the time and trouble to get the transit line exactly in the centre, as then the preliminary line answers for the location. But if improvements are to be made in the alignment, then it matters little if the transit line is not always in the centre; for a line must later be located on the ground at the proposed centre, the only difference being that in running levels fewer are needed if the transit line is in the centre of the road.

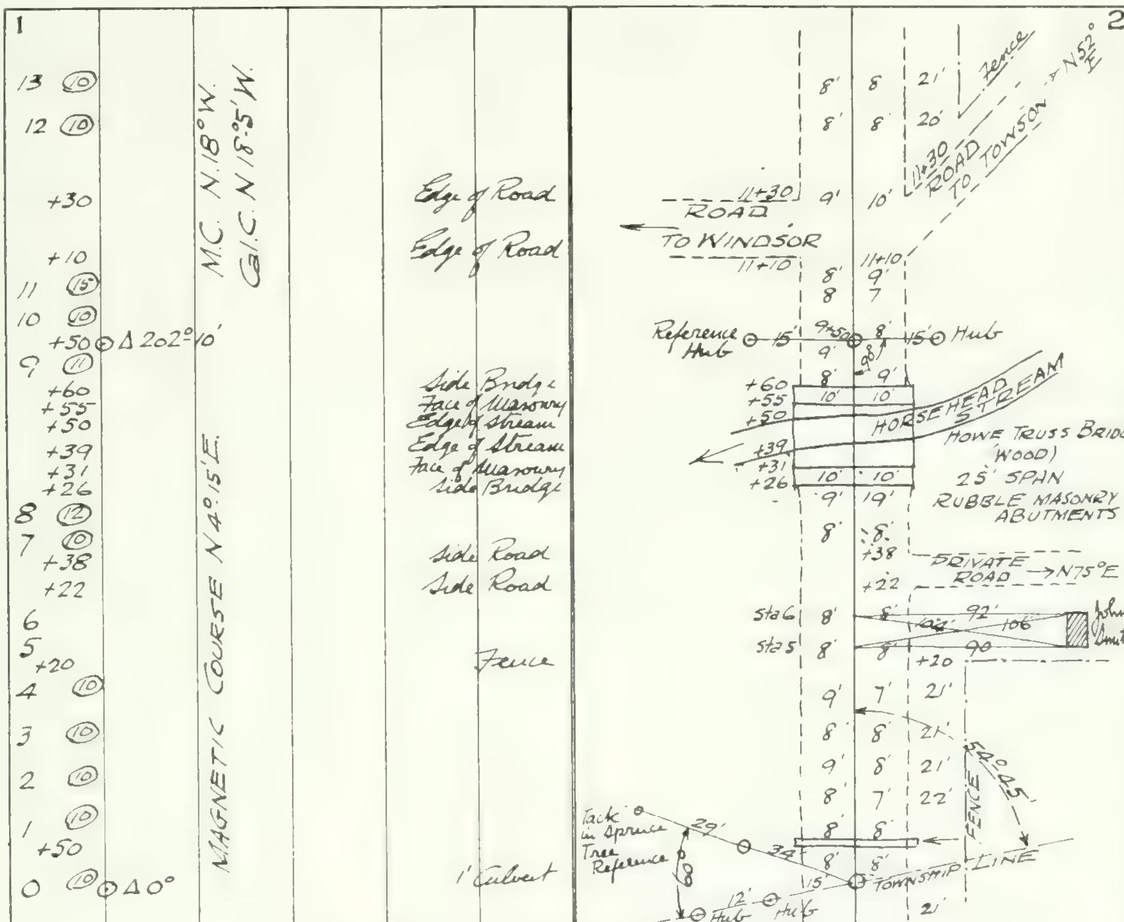

Fig. 1.—Sample Page of Transitman's Note Book.

Establishing Reference Points.—To start the survey, a point is selected at any definite place, as at the intersection of two roads, a town line, an established meridian, etc. It is not possible to drive wooden hubs into the roadway, as they will be destroyed by the traffic. A better plan is to use spikes for transit points. An 8 or 9-in. spike will give a good mark. A boat spike is preferable, as it does not bend as easily and has a good head on it, but a wire spike will answer the purpose.

Then the transit line should be projected straight along the road in the direction in which the survey is to run to the first turn or top of the first hill. To tie this line in, an angle should be turned between the projected line and that already established, at the intersecting road, town line, or meridian. Then a magnetic course should

be read on each line. The point established thus, becomes zero, the angle and magnetic courses give the location of this point, and the work of chaining is ready to commence.

A station is made every hundred feet. At each station the distance is measured to each side of the road, to the fences, if any, on each side, and to other features that may be found. The plus stations of all culverts, pipes, etc., are taken, and the measurements to each end from the transit line, all being recorded in the note book. Before moving the instrument ahead, each transit point should be referenced.

The easiest way of referencing a transit point is to turn a right angle to the transit line (this should always be to the back line, and not to the newly projected line; uniformity in this will prevent mistakes afterwards); measure off on each side a given accurate distance and put in a hub with a tack in it on each side. This method is accurate enough if the ground is about level, and if little if any grading is done afterwards; but if the ground is rough, or if a deep cut is afterwards made or an embankment built, the sight of one hub from the other may be obviously cut off and there is a chance of varying in making measurements.

A more accurate and satisfactory method is by means of two sets of hubs, so placed as to interset at the point to be referenced. For cuts, a hub on each reference line on each side of the cut will answer, but for embankments the hubs should all be on one side of the road, or at least the two hubs on one line should be on the same side. This allows the point to be placed back on the transit line by an intersection, measurements being entirely unnecessary. As near as possible, these reference lines should be at right angles to one another, as better work can be done in replacing the point. This, though, is not absolutely necessary. It is well to make measurement from the transit point to the reference hubs, as this is an aid in locating them afterwards, especially if bushes have grown up. One of the two reference points can often be placed on a tree by blazing and driving in a tack. Other methods of referencing will suggest themselves, but the last one described, with variations to suit local conditions, is the safest and best.

Party System.—In running the transit line the work can be divided as follows: The transitman runs the transit and keeps the notes. The head chainman makes all the measurements and calls them out to the transitman. He selects the places for hubs and spikes. He runs the front transit rod or flag, giving all foresights. Under his direction the rest of the party works. The back chainman holds the back end of the chain, assisting in making measurements, calls out the last station number, and carries along any extra stakes. While the transitman is moving up the back chainman assists in making hubs and stakes, or in cutting away bushes and trees that may be in the way. The head chainman should be ready at all times to set up the instrument for the transitman, should the latter need the time to make record of notes.

The axeman makes the stakes and hubs, carries a supply along with him, marks the stakes, calling back the numbers to the back chainman. He also drives the stakes and hubs, and assists the head chainman in making side measurements. The back flagman gives a back sight whenever needed, makes stakes and hubs in his spare time, and, if necessary, helps cut out bushes and trees. He carries along any extra baggage. Every man in the party should be provided with a piece of keel or marking crayon, so that time be not wasted in marking or re-marking stakes.

Features of Importance in Transit Work.—In placing the spikes or hubs, the latter should be used whenever possible, i.e., when the points come on the sides of the roads, as they will on sharp turns; they should be placed at some foot mark, or, if possible, at a station or plus 50, as this makes plotting easier and more accurate. Generally speaking, every transit point means that there is an angle in the line. A few may be points on long tangents, but these can be treated in a manner similar to those that have angles.

There are two methods of turning angles in highway surveying. The first is to take a back sight with the vernier set on zero, then reverse the telescope of the instrument and turn the angle ahead to the right or to the left. The other method, which is in more general use, is to have the vernier set on zero and, without changing the telescope, to turn the angle through the entire arc. Thus an angle to the right will be less than 180 degrees, while an angle to the left, by the first method, will be more than 180 degrees. On a tangent the angle turned will be 180 degrees. When this method is used the angle is always turned to the right, that is, through the entire arc on the right of the transit line.

"Right" and "left" in surveys should have a distinct meaning. Standing facing in the direction in which the line runs, everything on the right is known as "the right" and the other side as "the left." No matter how the work is done afterwards, these two terms always mean the same, even if part of the line is run backwards. In working on the surveys all notes should be taken on the right at each station or plus, and then the left side is done. There are several advantages in this: (1) nothing is likely to be overlooked; (2) this saves calling back to the transitman upon which side the notes are being taken, as he knows everything is done on the right before his men go to the left; (3) the party soon becomes accustomed to this and thus useless steps are and time is saved, and (4) men knowing these facts are less likely to make mistakes.

All offset stakes should be set on the right, and all guard stakes on the same side, the marked side of the stake facing the point. Thus there can be no doubt as to where to look for these points.

The surveys made around improved property should be very complete. All houses and buildings within 100 ft. of the road should be located and general dimensions taken. The houses can be located from two stations, taking a measurement from each station or plus to each corner of the building, making four measurements in all. All private and public roads or cross roads touching the highway should be located on the centre line and the magnetic course of them taken. They should be measured to the house or for at least a distance of 200 ft. The width of such roads should be taken, or other important features noted.

For bridges, the plus of each side, the direction of the flow of the stream, the span of the bridge, and the width of the stream, if it varies from that of the bridge, should all be taken.

The notes for all of these should be recorded in the transit book. Extensive road improvements generally cover a period of many years, as the laws or acts furnishing the money frequently provide that a stated sum shall be expended annually, for a given term of years. This means that many changes are bound to be made in the engineering corps, so it is absolutely necessary

that all notes and records should be made in a manner that will not be confusing or difficult to understand.

Fig. 1 shows the two pages of a transit book, Station (Zero) O starting at a township line. The width of the road, i.e., the beaten track of travel, is shown at each station, and the distance from the centre line to the fences. A culvert is shown at Station 0+50 and a bridge at 8+26. A farm house with a private driveway alongside is shown between Stations 5 and 6. At Station 11+10 are shown cross roads. Magnetic courses are taken on all lines and roads, as shown in the notes. On the transit line the magnetic course is taken and from it and the angles calculated courses are recorded. If the road-building is to be done at once this is all that is necessary, but if the work is to last over a number of years it is well to take into consideration the magnetic bearing from the true north. At Stations O and 9+50 are two transit points. The two methods of referencing these points are shown, viz., at Station O by two lines with two hubs on each, and at Station 9+50 by two hubs at right angles to the back tangent. The notes are run up the page, although some prefer them downwards. The writer's preference is to start at the bottom of the page. Then the notes are kept as the line is run and the man facing the line has his notes in the same position, preventing mistakes being made in recording measurements on the right and left.

In making the surveys, all the work should be done in a systematic manner. The transitman should keep his notes up in the field, leaving nothing to be put down at night. He should, as soon as he sets up his instrument on a new point, take a back sight and reference the point. This gives time for the flagman or chainman to go ahead and establish a foresight, which can be changed to suit the men chaining if necessary, as the first point may be found to be 9+42.6 which can be changed to 9+50. Then the transitman should read his angle, meanwhile letting his needle swing to take the new course. This done, the work of chaining can be started once more. As each station is measured in, the side measurements should be made and called back to the instrumentman, or recorded in a temporary note book if the distance is too great to call. It should be made a rule to take all measurements to the right before going to the left. This prevents confusion and mistakes, saving much calling of names, as at Station 13 it will be seen that the first measurement, 8 ft., means to the edge of the road on the right, the next 21 ft. from the transit line means to the fence on the right, then 8 ft. on the left means the edge of the road, and with the chainman going ahead the transitman knows there are no other notes to be taken. Men can work several thousand feet in front of the instrument in this manner without confusion or error.

It is not possible to drive stakes on the transit line, except when the line is run on the side of the road or for a trial line. Then the stakes should be driven at each station, with the marked side facing the instrument or zero point. When the stake cannot be put at the measured station, it should be offset to the right-hand side of the road, always on the same side, and at right angles, as near as possible, to the transit line. The marked side of the stake should face the station point and the offset in feet should be marked on the stake below the station number, with a circle around it. This same offset should be recorded in the transit book at each station with a circle around it, as shown in Fig. 1. This allows of the stake being found easily if it is broken off, and is a help afterwards. To save time these offsets can be marked in the book on a rainy day or as the party is going over the line later.

At hubs or spikes the guard stakes should always be set to the right with the marked side facing the point. Uniformity in this is a great help afterwards. At all pluses, references, etc., it is well to mark the station number on the stake, as well as the plus or reference. Then, if the stakes are pulled up there can be no question as to where they belong. This means the saving of much time afterwards. At all transit points the guard stake should first be marked to denote that this is a hub or transit point. In marking stakes, space should be left at the top to mark a letter, as this line may afterwards be given a letter to denote it, or an "L" may be placed on it to show it is a located line upon which improvements are to be made.

Each night the transitman plots up his notes, and if any data has been overlooked it is taken the first thing the next morning. It is not well for him to use ink on his map until it is to be finished or sent to the office of the chief engineer.

(To be continued.)

CONSERVATION REPORT ON TRENT WATERSHED.

A report, entitled "Trent Watershed Survey," by Dr. C. D. Howe and J. H. White, of the Faculty of Forestry, University of Toronto, with an introductory discussion by Dean Fernow, will shortly be published by the Commission of Conservation. The area investigated is one in which the conditions are typical of those prevailing over thousands of square miles of cut-over lands in the Eastern provinces of Canada and for which it is desirable to formulate a policy of reconstruction and recuperation. The Dominion Government has a special interest in this region, as the capital invested in the Trent Valley Canal system amounts to upward of $10,000,000.

The report covers farming, forest, industrial, mining and tourist traffic conditions in the area considered. It shows that only 15,000 people inhabit the 2,100 square miles of the watershed (a decrease since 1901 of 15 per cent.), and that hardly 10 per cent. of the region has been cleared for farm purposes. The soil is altogether unsuitable for agriculture, and run-down and abandoned farms are to be found in large numbers. Nearly 200 farms were for sale for unpaid taxes in 1911 at 6 cents per acre.

Practically all the pine has been removed. The whole area has been burned over at least once. Almost one-half the area is covered with young and second-growth trees of the poplar-birch type, the result of fires.

It was found, however, that enough hardwood and wood of the poplar-birch type remain to warrant the adoption of a policy of conservation, and Dominion, Provincial or municipal ownership of the territory in question is suggested by the Commission as an initial step in that direction. Other recommendations are: the re-possessing by the Province of the licensed lands which have practically ceased to produce the quantity of logs contemplated under original licenses; the imposing of restrictions on existing limit holders, tending to protect the forest growth; the appointment of a forester charged with the surveillance of the region; the perfecting of a fire-protection organization, building of look-out stations and watch towers, and appointment of the game-wardens as fire-wardens.

NOTES ON SAND, STONE AND GRAVEL FOR SALT WATER CEMENT.*

By Harrison S. Taft, Seattle, Washington.

THE success to be attained by placing concrete structures in sea water depends upon, first, the possibility of using cement in salt water, and, second, an economical design. Without doubt a great many prominent engineers hesitate to recommend the placing of concrete structures in sea water more from a chemical point of view perhaps than from a structural one. If the material out of which the structure is to be built cannot be depended upon to maintain its integrity when exposed to the elements, the very best design will not solve the problem.

Therefore, the chemistry and manufacturing side of the cement industry becomes a question of prime and vital importance as regards cement to be used in sea water structures. The next question is that of impermeability; otherwise the concrete might slowly deteriorate under the action of the chemicals in sea water, since perhaps it is impossible to reduce such actions to a negative quantity. In freezing climates this question of impermeability becomes a very serious one, due to the destructive action of alternate freezing and thawing.

Cement.—The first and chief difficulty that has to be overcome in using concrete in sea water is "the peculiar chemical disintegrating action of the magnesium and other sulphate contents of ocean water upon the alumina compounds in the cement," followed "by the abrasive action of the water of the ever-restless sea" upon the chemically affected and softened concrete.

To overcome the chemical action of the sea water upon concrete the Germans have placed upon the market a brand of cement called "iron ore cement," wherein the alumina content of a cement is partly replaced for fluxing purposes by iron which is not affected deleteriously by the magnesium and other sulphates of the salt water; thus inoculating the concrete, as it were, against attack. The world-famed Teil Cement Works does not allow more than 2 per cent. alumina and absolutely no free lime in the cement which they manufacture for use in concrete structures standing in sea water.

Another German product called Puzzolan-Portland Cement, especially devised for use in sea water, has been on the market some 16 to 18 years. This product is a mixture of Portland cement and a natural puzzolan (a volcanic ash), or of a Portland cement and an artificial puzzolan (blast furnace slag of a certain chemical composition), the mixture being 30 to 60 per cent. puzzolan and 50 to 70 per cent. Portland cement.

The chemical action in hardening results in a Puzzolan-Portland hydraulic cement invulnerable to sea water. Although the mixing can be done on the job, it is far preferable to pulverize the two ingredients together in the mill at the cement factory.

A set of extensive tests made by the German government shows higher strength for Puzzolan-Portland cement concrete both in tension and compression than for pure Portland cement concrete. It has also been demonstrated that the former resists salt water far better than the latter. From an economic point of view in producing resistance to the action of sea water a barrel of Puzzolan-Portland cement has been found to be equal to two barrels of pure Portland cement.

From information obtained in regard to these two German cement products, concrete made of them and placed in salt water has been giving the best and most satisfactory results. Thus a vast amount of salt water concrete construction is being carried on in Germany and other foreign countries, due no doubt to their overcoming the action between salt water and the cement.

Though there have been a number of disastrous disintegrations in using American Portland cements in salt water, on the whole American Portland cement seems to have worked quite satisfactorily in sea water.

Such cement "has the power of armoring itself against the action of the magnesium sulphates of the sea water by the formation on its exposed surfaces of a film of lime carbonate." This film appears to serve as an effective protection to the concrete structure in comparatively still waters, but where the waters are greatly agitated this film has no opportunity to form. Hence "the calcium hydrate set free by the decomposition incident to the hardening of the Portland cement is washed away," leaving the concrete structure unprotected against "further inroads of the deleterious chemicals contained in the sea water."

To reduce the question of the chemistry of sea water cement to a more technical form, Mr. J. M. O'Hara, in a report to the Southern Pacific Railway, states: "The magnesium sulphate present in sea water acts upon the calcium hydrate of the cement, forming calcium sulphate, and further, this calcium sulphate combines with the alumina of the cement, forming calcium sulpho-aluminate, which last compound gives rise to the swelling and cracking of the concrete."

Mr. O'Hara also states that though it may seem that a cement in which the alumina has been replaced by iron is desirable, it would be impracticable, however, to replace *all* the alumina in a cement by iron oxide, as "a product resulting from the burning of ferric oxide and calcium carbonate does not possess hydraulic properties." He further says that whereas it seems to be universally accepted by engineers and others that a dense concrete is impermeable to sea water, the results of tests made by him do not seem to bear out this theory, unless the cement used has the inherent qualities to resist the disintegrating action of the sea water.

In discussing the subject of mass concrete in block form for breakwater purposes, William Matthews, a prominent English engineer, says:

"In a tideway, where mass concrete is used, it is of the utmost importance that the relative sizes and proportions of the aggregate should be such as to produce an absolutely watertight material. The infiltration of sea water into green or unset concrete and its subsequent exudation due to tidal action causes the magnesium salts in the sea water to withdraw a portion of the lime of the cement in the form of calcium salts, leaving a deposit of magnesia in its place. It is this magnesia, derived from sea water, either alone or mixed with lime from the cement, which constitutes the white substance deposited in the interstices of porous concrete between high and low water. Concrete so affected possesses but little strength and its failure is only a question of time."

As the result of his research upon the use of cement for sea water purposes, the eminent Dutch chemist, V. I. P. de Blocq van Kuffeler, Hoorn, in a paper read before International Association for Testing Materials, New York, September, 1912, states "that the decomposi-

*From Metallurgical and Chemical Engineering, January, 1914.

tion of the concrete is caused by the salts contained in sea water; the sulphates are the most to be feared owing to their action on the unstable compounds of lime which are formed during the very long period taken by the cement for hardening. Evidently it is during the first part of this period that the action of sea water is the most detrimental, i.e., when the compounds are least stable. Actual experience has confirmed this theory."

He also says that "when such material as trass or puzzolanes are added to the cement, one part of the lime forms compounds with silicates, the other compounds mentioned becoming more stable and the influence of sea water is less to be feared"; that "fine trass increases the impermeability of the mortar"; and "if the concrete has been hardened in a damp atmosphere the influence of the trass is still more marked."

Irrespective of the brand, a cement to be successfully used in salt water must be of the very best quality, of a fine pulverization, and thoroughly analyzed and tested for its chemical properties. Every means should be taken to avoid too much alumina in a cement that is to be used in salt water. The per cent. of alumina should be low, that of silica high. The cement should also be as free as possible from gypsum.

A cement of the slow hardening order should be avoided. Distinction between "setting" and "hardening" of cement should be kept in mind. A slow setting but quick hardening cement is the proper kind to use in salt water.

Not only must the cement manufacturers provide the engineer and the contractor with a cement of the proper chemical constituents, but the concrete made from said cement must be dense in order to fulfil all the requirements of a salt water concrete. This apparently is what the Germans have been doing, and it explains why they are able to get such excellent results in concrete work in Germany as well as in other foreign countries. It is an exceedingly important question for domestic cement manufacturers to consider.

As considerable stress has been laid above on the German method of manufacturing cement for sea water purposes it is fitting to still further consider what Herr Blocq van Kuffeler says upon the question of using cement in concrete placed in salt water. He states that the following points should be most strictly adhered to in using concrete in salt water:

(a) Artificial (slow-setting Portland) cement of first-class quality and hardening very uniformly should be used to the exclusion of all others.

(b) The mixing of the material and the ramming of the concrete in strong and tight casings must be performed with the greatest possible care.

(c) The use of trass (or puzzolanes) is recommended.

(d) The concrete must be compact and the composition of the mortar should not be below 1 part cement, ½ trass and 3 sand, or 1 part cement, 1½ sand.

(e) Allowing the concrete to set in a damp atmosphere before placing "in situ" greatly increases its resistance to attack by sea water and is recommended where possible. When the concrete is exposed to the infiltrations of sea water immediately after manufacturing its composition should be richer.

In conclusion he says a carefully considered composition, most careful manufacture, the use of excellent cement with trass (or puzzolan) and hardening in a damp atmosphere are the most efficient means of satisfactorily ensuing the preservation of reinforced concrete in maritime works.

Laboratory or Similar Tests.—For several years past the United States Government has been carrying on a set of tests at Atlantic City and elsewhere to determine the exact fact as regards the use of cement in sea water. A preliminary report of these tests has recently been issued by the government. Although three years is a comparatively short time for determining the absolute facts under actual conditions, the results of these tests so far published seem to indicate that the success of using concrete in sea water depends in a large degree upon careful and proper working of the material rather than upon the special brand of the cement itself. It is true that some cement works better than others in sea water, those with a low percentage of alumina giving the most satisfactory results, but with an impermeable structure as the prime factor in all cases.

Although these government tests will no doubt in time give the concrete engineer the absolute facts as regards the situation, the engineers of this country already have the actual experience of some 18 years of foreign practice by which to guide themselves. No doubt the final results of these United States government tests will simply substantiate what has already been learned regarding the use of cement in sea water by foreign chemists, viz., an impermeable mass with a low per cent. of alumina in the cement used.

In the early part of 1909 twenty-four test pieces were made of concrete and hung from one of the wharves at the Charlestown Navy Yard, Boston Harbor. These test pieces were 16 feet long, 16 inches square and made with a core for part of their length so as to provide a means of determining their permeability. Several different kinds of cement were used in making these pieces and the concrete mixed in various proportions; some of the pieces being made dense, others porous. These pieces were hung from the pier in such a way as to have their lower ends always in water, while the tops were seldom submerged. At the end of the first two years of immersion one of these test pieces showed marked signs of deterioration, while others were in good condition. Later reports go to substantiate the truism mentioned above, since the pieces made of a porous nature have deteriorated somewhat with those of a dense nature are in the same perfect condition as the day they were made.

Though these laboratory tests will go a long way in revealing the true facts and actual conditions it is necessary to guard against in the use of cement in sea water, "it must ever be kept in mind that the phenomena, both physical and chemical, in the sea cannot be reproduced exactly in laboratories on land." Consequently laboratory tests will never give the real truths of using cement, and hence concrete, in sea water as will actual experience. Thus the actual experience of foreign engineers in the use of concrete in sea water structures and the modes pursued by them are far more valuable to the American engineer than any short time test made in this country.

Admitting that laboratory tests are absolutely necessary and that the world cannot get along without them, such tests must be considered hand in hand with actual experience and as supplementary thereto. The fact that local conditions and local material will seriously alter cases brings home to the engineer the truth that he must not judge foreign experience by home conditions, and vice versa, until the actual conditions covering each are known and is used as the complement of the other.

Waterproofing Compounds.—In view of the claims made by waterproofing experts as respects the excellency of their product, it is proper to quote from an article en-

titled "Test of Water-Proofing Material," U.S. Bureau of Standards, No. 3, August 22, 1911: "Portland cement mortar and concrete can be made practically water-tight or impermeable (as defined below) to any hydrostatic head up to 40 feet, without the use of any so-called 'integral' waterproofing material; but in order to obtain such impermeable mortar or concrete, considerable care should be exercised in selecting good material and aggregate, and proportioning them in such a manner as to obtain a dense mixture. The consistency of the mixture should be wet enough so that it can be puddled, the particles flowing into position without tamping. The mixture should be well spaded against the forms when placed so as to avoid a formation of pockets on the surface.

"The addition of so-called 'integral' waterproofing compounds will not compensate for lean mixtures, nor for poor material, nor for poor workmanship in the fabrication of the concrete. Since in practice the inert integral compounds (acting simply as void filling material or in the nature of a lubricating material) are added in such small quantities, they have little or no effect on the permeability of the concrete. If the same care is taken to make the concrete impermeable, without the addition of waterproofing material, as is ordinarily taken when waterproofing materials are added, an impermeable concrete can be obtained."

In connection with this part of the subject it may not be out of place to speak of "oiled concrete" for waterproofing certain classes of concrete structures. It is of such recent development that sufficient opportunity has not been given to determine its real merits for universal waterproofing purposes especially as regard concrete structures standing in sea water. So far as known there are no records "of any such tests ever having been made" and some chemists have positively stated that it will be impossible to make oiled concrete a success for sea water purposes.

On the other hand, I. Hiroi, a civil engineer of Japan, has stated: "Of more than 12,000 concrete blocks of all sizes and of different compositions, used by the writer in harbor works during the past ten years, there has not been the slightest indication of failure. On the contrary, the protection given by coatings of animal, vegetable and mineral origin to the surfaces of the blocks has rendered them almost impregnable against the incessant action of the sea. The protection thus afforded by nature, which would render a comparatively weak artificial stone, when properly made, as lasting as the natural stone used as its ingredient, is unknown in laboratory experiments."

Sand, Gravel, Stone.—The sand used in concrete placed in sea water must be clean, sharp and free from all foreign material. The stone must also be clean and sound. Gravel, if used, must likewise be clean and of proper size. The chemical composition and mineral structure of the stone, sand and gravel for use in proposed sea water concrete structures, should be known absolutely beyond all doubt. Since it is of great importance that concrete used in sea water should have the maximum density, the mechanical composition of sand and gravel should be known and modified, if necessary, by adding screened material.

For the same reason that an igneous rock or material is far better in the construction of a fireproof concrete structure, it is absolutely necessary in salt water concrete to use aggregates that will not disintegrate or fail when exposed to the elements of the salt water and the action of the sea.

Mr. John R. Freeman has called the attention of engineers to the fact that "here and there are banks of sand and gravel which, upon ordinary inspection, appear ideally perfect for making mortar and concrete, but which are nevertheless dangerous in the extreme, and all because of some ultra-microscopic content, probably similar to tannic acid (in a colloidal film around the sand grain), which works in some mysterious way to prevent the union between the cement and the sand grains."

Mr. Freeman cites an occasion where he found at the site of a proposed structure what promised to be a most economical resource in a shape of excellent sand and gravel; but upon being tested some of the samples of 1:3 mix, six days in water, hardly maintained their integrity while being placed in the clamps and before any load was applied. The cement was of a brand that had given excellent results with other aggregates.

E. E. Free, an investigator, engaged upon physical and chemical investigations for the Bureau of Soils, has noticed analogous phenomena in studying the relative fertility of different soils. Mr. Free states that:

"In popular terms the situation can perhaps best be explained by considering that an extremely thin film of a complex form of tannic acid surrounds each grain of the troublesome sand and prevents its attachment to the cement. These complex organic acids have a strong tendency to spread themselves thinly and strongly adherent over the outside of the siliceous material. The reason why one particular brand of cement is able to break through this filmy barrier so as to get a firm grip upon the sand grain is because of its containing a small quantity of some form of alkali that unites with this acid film or somehow changes its colloidal state."

It is admitted that these defective sands are the exception rather than the rule. Though some engineers and contractors may think the whole investigation a highly interesting laboratory amusement, of no value whatsoever to practical construction, the fact remains that there are sands whose availability for concrete aggregate cannot be predicted under any of the ordinary methods now in vogue, and that ever so often one of these sands gets into a structure to its detriment and perhaps failure if the structure stands in sea water. Therefore the sand and stone should be tested as carefully as the cement for salt water purposes.

Of equal importance is the utmost care that must be taken in mixing and placing the concrete, in order to obtain an impermeable mass throughout. Superintendents and concrete foremen should also be careful to see that injurious acids do not get into the sand, gravel and stone of concrete to be placed in sea water by the working force urinating upon the material. Great care should likewise be taken to exclude from all material entering into the manufacture of concrete such things as scraps from lunches, tobacco and spittle of those chewing tobacco. It is known that an amount of sugar, even as small as ¼ per cent. will entirely prevent a batch of cement from hardening. Since the extract from chewing tobacco contains sugar or glucose, any such extract that enters into the concrete will prevent the cement from setting. There are other organic compounds whose presence in the concrete will have a marked effect on the hardening of the cement, and the utmost means should be taken to exclude such detrimental material from all concrete to be placed in sea water.

Mixture.—In connection with the concrete dock work of the Thames River the practice seems to have been to use "a gravel of moderate size combined with two-thirds of its bulk of sand mixed with one part of cement to every two parts of sand," viz., 1:2:3 mixture. It is stated that with such a mixture there will be no fear of the results if the concrete is properly mixed and handled. The concrete is also given a grout coating after it has set and hardened.

In building concrete breakwaters in Holland it has been found that mass concrete blocks made of 1 part Portland cement, ½ part trass (the trass being a Puzzoland which is found near Andernach on the Rhine), 3 parts sand and 5 parts Rhine gravel, enabled the blocks to resist the corroding action of the sea water. Of more recent date they have been using a cement-trass-concrete of 1 part cement, ⅓ part trass, 2 parts sand and 3⅔ parts gravel.

In Germany a mixture of 1 part cement, ½ part trass, 3 parts sand, 4 parts gravel, is very often used.

During recent years a very rich mixture, viz., 1:1½:3, has been used in nearly all the important sea water concrete structures built in England and France.

In the harbor development of Otaru, Japan, a proportion of 1 part cement to 2 parts sand for the mortar gave superior results; the average concrete mixture used being "1 cement, 2 sand, 2 gravel and 2 broken stone, before the tuff was put in, the ratio equivalent by weight of the cement to the tuff being, 1 cement to ½ tuff." By volume this combination reduces to:

1.0 cement; 0.8 tuff; 3.2 sand; 6.4 ballast.

In the Netherlands Portland cement concrete with the addition of trass has been used almost exclusively. Though Herr Blocq van Kuffeler recommends a mortar of 1 part cement, ½ part trass and 3 parts sand mixture for sea water structures, he states that concrete of the above composition will remain in a perfect state of preservation "provided it has been hardened in a damp atmosphere before placing *in situ*, but is apt to give disappointment if the concrete is exposed to the infiltration of the sea water immediately following manufacture." Under the latter conditions he recommends a richer composition—at least 1 part cement, ½ part trass, 2½ parts sand. When no trass is used he says a mixture of 1 part cement, 1½ parts sand should be used. He also says that whereas mortars of 1 cement, 1½ sand and of 1 cement, 1½ trass, 3 sand can be used with safety in marine concrete work, the latter will create a saving in cost of considerable extent. It is also of great importance that the cement and the trass should be thoroughly mixed before the sand is added.

As respects the use of salt water in the manufacture of concrete, the same eminent chemist states that since the amount of salts introduced into concrete by diffusion when the concrete is exposed to sea water is vastly in excess of any salts that might be introduced into the concrete "by the small quantity of water used in its manufacture—the use of salt water in the making of concrete is in all probability prejudicial to only a slight extent."

As in ordinary reinforcement work, when the reinforcement is complicated, a smaller size gravel should be used with their homogeneity increased, a size of not over .116 cubic inch being recommended by a leading authority for marine reinforced concrete.

Mr. I. W. Sandeman, in his paper upon "Action of Salt Water Upon Concrete," states that for salt water purposes the maximum proportion of the sand in the mortar must not be more than twice that of the cement, and the mortar must exceed the voids in the aggregate. The exact grade of the sand mixed with the cement plays an important part in obtaining impermeable concrete, a hard, coarse sand giving the best results. It was the knowledge of this important point and a thorough investigation of it that enabled the noted Italian engineer, Com. Luigi Luiggi, to construct a dry dock at Bahia Blanca, in 1902, that resulted in a perfectly watertight job. The utmost care was taken in the construction of this dock, with special attention to the bonding of old concrete to the new.

As respects the advantages of using crushed stone over gravel, Mr. Staniford, chief engineer of the New York Dock and Ferry Department, states that his department does not find gravel a suitable material to use in mass concrete when subject to the action of the sea water, and that the broken, hard trap rock, so commonly used in New York City and vicinity, gives far better results in such kinds of concrete than are obtained with gravel. From the author's own experience with broken stone and gravel, he prefers stone, especially if it is trap rock.

Conclusion.—In the final analysis, the successful use of cement in concrete structures standing in sea water boils down to the use of an impermeable concrete made of a cement low in alumina and otherwise suitable for salt water purposes. The former is the problem of the concrete and construction engineer; the latter the problem of the chemist and cement manufacturer. To obtain an impermeable concrete a very rich mixture must be used, the exact proportion between the finer and coarser material being dependent upon the per cent. of voids.

If possible the concrete should be hardened in a damp atmosphere in order to assist the chemical reaction of setting before being placed *in situ*, or before being subject to the action of the sea water, especially so if the sections are small.

The mixing and placing should be closely watched and done with the greatest care, far more so than in the ordinary building work, in order to ensure that each particle of the sand and coarser material is well covered with cement and mortar respectively. A concrete of a medium or plastic consistency will ensure far better results than a wet or dry mixture.

"In the Netherlands experience has furnished conclusive examples as a guide for future construction, with a sufficient degree of safety, as to justify the further application of reinforced concrete in marine structures, which after all are only the work of mortals and not destined to last for eternity."

Mr. W. C. Phelan of the United States Geological Survey, states in a report upon the aluminum industry that the year 1912 was marked by a notable increase in the use of that metal, more than 65,000,000 pounds being consumed, compared with 46,125,000 pounds in the preceding year. Not only was there an increase in the domestic production, but there was a decided growth in the imports [illegible]. The domestic production of bauxite during 1912 was 159,865 long tons, valued at $768,932. Compared with the output in the preceding year, these figures represent an increase in quantity of 4,247 long tons, and in value of $[illegible]. It is significant, however, that the importation of metallic aluminum of different grades increased enormously in 1912, a fact which may possibly account for the small increase in the production and the decrease in the imports of bauxite.

PROTECTION AGAINST FOREST FIRES ALONG CANADIAN RAILWAYS.

SINCE forest protection is the first essential to the development of forestry practice, and since fire has always been the chief enemy of the forest, with the railways as one of the principal agencies responsible for destruction, it is proper to emphasize the remarkable improvement which has taken place in the railway fire situation during the past year. The Commission of Conservation was instrumental in securing legislation which empowered the Board of Railway Commissioners to make regulations for fire protection along the railway lines. Under date of May 22nd, 1912, the Board, by Order No. 16570, covered the railway fire situation very fully, and placed upon the railway companies, subject to the jurisdiction of the Board, the responsibility for taking all measures necessary to the prevention and control of fires due to railway operation. As was reported at the annual meeting of the Commission in January, 1913, the Chief Forester for the Commission was also appointed Chief Fire Inspector for the Board of Railway Commissioners.

During 1912, the railway fire protection work was organized only in the West. In 1913, the organization has so far as possible been extended to the East. As announced by Hon. Clifford Sifton, chairman of the Commission, at the annual meeting in January, 1914, the plan has been consistently followed throughout of building up an inspection staff through co-operation with the existing fire-protective organizations of the Dominion and Provincial Governments, within the territory already covered by the jurisdiction and organization of each. Thus, the Railway Commission has appointed as officers of the Fire Inspection Department, a very considerable number of the officials of the Dominion Forestry Branch, Dominion Parks Branch, British Columbia Forest Branch, Department of Lands, Forest and Mines of Ontario, Forest Protection Branch of Quebec, and Crown Lands Department of New Brunswick. The principal work of these officials for the Board has been in connection with enforcing the requirements as to the patrol work and right-of-way clearing by the railways, though there has been a considerable amount of inspection of fire protective appliances on locomotives, in co-operation with the Operating Department of the Board. It will be seen that in this way the fire-protection work of the Board operates in complete control with the existing fire-protective organizations of the Dominion and Provincial Governments, and all unnecessary duplication is avoided.

In Nova Scotia, the proposed plan of co-operation has not yet been put into effect, pending the appointment of a Provincial Forester, who, according to the law enacted last spring, following the report by Dr. Fernow, on forest conditions in that province, will handle forestry work for the Provincial Government, as well as supervise the work of fire-protection in general.

To handle fire guard inspection in the prairie provinces, plans of co-operation have been developed whereby the Chief Fire Guardian of Alberta and the Fire Commissioner of Saskatchewan have been appointed officers of the Board. As to Manitoba, negotiations are now under way which, it is hoped, will result in a similar arrangement for co-operation by the Fire Commissioner of that Province.

The results which have been secured as a result of the co-operative handling of the railway fire-protection work have been admirable. The occurrence and spread of railway fires has been greatly reduced. The efficiency of the work is in direct ratio to the sufficiency and efficiency of the inspection staff made available by the various co-operating agencies. In the West, practically no criticism could be made on this score. The eastern provinces are somewhat more conservative, and the completion of the organization comes more slowly. However, assurances have already been received which will mean a very much more satisfactory organization in the east during 1914, and, as the work justifies itself by its results, further extensions may confidently be expected. For the most part, the railways have shown a decided appreciation of the work, and have endeavored to comply honestly with the various requirements. There is every reason to believe that henceforth the railways will be found among the minor—instead of the major—agencies responsible for damage by forest fires.

In order to bring this prediction fully into effect, further action is necessary respecting two classes of railways not under the jurisdiction of the Railway Commission. These are the various provincially chartered railways and the Government railways.

As to the first class, action in the form of new legislation is needed in the Provinces of Nova Scotia, New Brunswick and Alberta that railways chartered by these Governments may be required to observe the same precautions that are now required of Dominion chartered lines. These matters have already been taken up with the Governments concerned. In Ontario, existing legislation may possibly be adequate, but there does not seem to be sufficient provision for enforcement.

The situation as to fire protection along the Government railways has shown marked improvement during the past year. Following representations made last spring by the Commission of Conservation and by the Government of New Brunswick, a system of special fire patrols was established along the National Transcontinental Railway between Moncton and Edmundston, N.B., and special instructions were also issued to all employees in regard to reporting and extinguishing fires along the railway line. Much, however, still remains to be done before the system of fire-protection on Government railways will be as intensive as that now required on lines subject to the Railway Commission. Along both the Transcontinental and Intercolonial, there is very much to be done in the way of removing inflammable matter from the right-of-way. This situation is especially serious on the Transcontinental, and will mean a very serious fire risk until the debris is destroyed. It is also necessary that provision be made for special patrols on both lines through forest sections, and that special instructions be issued to all employees, similar to those issued on the New Brunswick Division of the National Transcontinental. Reports also indicate that a closer degree of inspection of fire-protective appliances on locomotives is needed, especially as to those running on portions of the Transcontinental not yet regularly opened for traffic. These various matters have for some time been the subject of discussion between our officers and the Department of Railways and Canals.

The suggestion has now been made to the Minister of Railways that all of the Government Railways should be placed under the operation of the regulations issued by the Board of Railway Commissioners. There can be no doubt that uniform regulations and a uniform inspection would be in the highest degree desirable and would conduce to effective fire-protection. The suggestion is at present under the consideration of the Minister of Railways.

CONTENTS OF THIS ISSUE.

HIGHWAY SURVEYING.

The attention of our readers is directed to the article entitled "Highways and Highway Surveying," beginning on another page of this issue. The writer, Mr. Hauer, has had numerous requests during the past few years from both young and old engineers to write an article of this nature, whereby any civil engineer in taking up the practice of road work could undertake the special survey work connected with it intelligently and without the necessity of waiting to gain experience that he might deem necessary in order to do it properly.

The subject of road engineering is one of greatest importance in every province in Canada at the present time. Besides the opening of new highways, many communities that have borne expense and inconvenience for years in the upkeep of inadequate roads are awakening to the measure of economy which attends better facilities for transportation. The result is that more attention will be given during the next few years than ever before to the economics and location of country roads and to their construction and maintenance. The advent of motor-driven traffic has precipitated a complexity of shortcomings in previous practice that necessitate placing the care of such roads in the hands of engineers so that the scientific principles involved may be properly applied.

The article referred to has been specially written for *The Canadian Engineer*. The author's broad experience in construction work has equipped him with a knowledge of those details which determine success or failure, and how to achieve the one and evade the other. There is added to this the fact that the first article Mr. Hauer has ever written for any Canadian paper is the one on highway surveying, which he has prepared specially for this journal.

RESPONSIBILITY IN CONTRACT WORK.

Engineers cannot always throw the entire responsibility for the success of the construction of every job upon the shoulders of the contractor. It may be a comparatively easy matter, especially with the assistance of an able solicitor, to prepare a specification by which a municipality runs no risk whatever, but such a specification cannot always be enforced.

To begin with, it is a difficult matter to take away the contractor's right to appeal to the courts, should the specification mean probable confiscation of the work under certain conditions. Even though an iron-bound specification be prepared, such that allows the contractor no resource to the law, and that the engineer is the sole arbitrator of the value of the work done under the specification, the latter cannot always force the acceptance of the terms of the specification. This is especially true where the work is so large that it requires a bonding company's security. If this company believes the specification to be so rigorous as to be unfair to the contractor it will refuse to issue a bond; whereupon the engineer will then have to accept a bid without the bond, or modify his specification to the reasonable wording in which it should have been first written.

A notable case in point is the specification for the Toronto mechanical filtration plant, for which tenders were received a couple of weeks ago. The Department of Works was so anxious to safeguard the city in every possible way that a feeling was created among the bonding companies that the specifications prepared by the Department were entirely too arbitrary. We understand,

unofficially, that as a result not one of the four tenders received was accompanied by the required bond. Moreover, it is believed that some, if not all, of the tenders were submitted with the condition imposed that certain modifications be made in the specifications.

Nothing but praise is due the Toronto Department of Works for its over-anxiety to protect the city's interests; but the case again calls attention to the fact that there are certain kinds of risk in every contract that must be shared by both parties to the contract. Toronto cannot reasonably expect its filtration plant to be an exception to the rule.

THE CONSERVATION COMMISSION AND ITS PUBLIC HEALTH MEASURES.

Several useful publications in the interests of public health were issued during 1913 by the Commission of Conservation under the direction of its medical adviser, Dr. Chas. H. Hodgetts. A compilation of the public health laws of the Dominion, as suggested at the Conference of Health Officers in 1912, a work which was urgently required and which is very much in demand, was one of them. A report was also compiled for the special committee of the House of Commons having under consideration two bills regarding the prevention of pollution of waterways. An illustrated pamphlet was prepared and printed in both English and French, and 150,000 copies distributed, having reference to the collection and disposal of garbage in cities and towns.

The question of sewage disposal as practised in England and Germany has been carefully studied by Dr. Hodgetts, and a report thereon is now in preparation.

Perhaps the most important development in connection with the subject of public health has been the determination of the Commission to take up more actively the question of Housing and Town-Planning. It will be remembered that some attention was given to this subject in the early stages of the Commission's work, and public addresses were delivered with the object of stimulating action by municipalities throughout the Dominion.

Gratifying results have followed from this movement, a great deal of attention having been given to the subject in various places, the most practical work that has been done up to the present time having taken place in the city of Toronto.

At the fifth annual meeting in January last, the chairman announced that with the object of strengthening and advancing the movement in favor of more scientific town-planning and more vigorous attention to the housing requirements of the population, the Commission had determined to act as the host of the National City Planning Conference, which will be held in the City of Toronto this spring. Arrangements are now in progress for the holding of that conference. It is intended, if possible, to make it the means of exciting more direct and effective attention to the subject throughout Canada; and also to procure, if possible, a body of substantive legislation which will enable those who are desirous of promoting progress in this important department of social welfare to act under the sanction of law.

For this purpose there has been appointed a special committee, of which Colonel Jeffrey H. Burland is chairman, having for its duty the preparation of draft legislation. It is the intention to have the recommendations of this committee submitted to the various Governments of the Dominion, and after receiving suggestions from them, to submit the whole matter to a Committee of the National City Planning Conference, with the object of getting a thoroughly digested measure. When this has been done an effort will be made to secure the enactment of the proposed legislation in the different Provinces of Canada.

LETTER TO THE EDITOR.

Billings Bridge, Ottawa, Ont.

Sir,—While appreciating the criticism concerning the floor slab on above bridge given in your issue of February 5th, the writer (the designer of the bridge) would take issue with "Bridge Engineer" as to the strength of this slab.

At the outset, let me say that 4½ in. was the effective depth of slab, the stringers being spaced for roadway at 3½ ft. As the span of slab is less than the width of roller, the roller load of 16,000 lbs. can be reduced to $\frac{3\frac{1}{2}}{4}$ of 16,000 lbs. = 14,000 lbs. This load was assumed to be distributed over an area of 1.16 ft. perpendicular to, and an area of 3.5 sq. ft. parallel to, the axis of the roller. This gives a load of 3,450 lbs. per sq. ft., and is about the worst condition of loading.

This gives a bending moment of 3,500 ft.-pds. using the formula $\frac{w\,l^2}{12}$ for continuous slabs. Dividing this by the moment of resistance of the steel gives the sectional area required per foot of width as 0.6 sq. in.

From this is derived a ratio of reinforcement of about 0.01%, and I fail to see where it is in any way disastrous.

To follow out the motor truck loading as mentioned, let us assume a concentrated load of 8,000 lbs. with a 12-in. wheel base. This will distribute the load over an area equal to 1.16 ft. x 1.83 ft., or 2.12 sq. ft., which gives a concentrated load per foot of width of 3,800 lbs. or, say, 4,000 lbs.

Using the ordinary bending moment formula for concentrated load, $\frac{W\,l}{4}$, gives a moment of 3,500 ft.-pds. and from it is deduced a sectional area per foot of width of 0.6 sq. in., or the same ratio of reinforcement as in the former case and this with a bending moment formula for a simply supported beam.

The figures for the distributing area are obtained in this latter case by assuming an actual wheel contact in a longitudinal direction of 4 in. passing at 45° through the 4-in. wood block and 1-in. sand cushion, and in a transverse direction by the 12-in. wheel base, passing down in the same way.

Expanded metal will be used for reinforcing.

ROBERT HENHAM,
Bridge Engineer.

Ottawa, Ont., February 13, 1914.

ONTARIO GOOD ROADS ASSOCIATION.

The annual convention of the Ontario Good Roads Association will be held in the County Council chambers on Adelaide Street on February 24th, 25th and 26th. The program as arranged provides for the reading and discussion of a number of papers on road construction and maintenance, having particular regard to conditions in Ontario. In view of the highway improvement proposals of the Provincial Government, this is expected to be an important gathering.

SEWER-PIPE AND ROOFING-TILE TESTS OF WESTERN CANADA CLAYS.

THE second part of a report on the clay and shale deposits of Western Canada has just been issued by the Geological Survey, Department of Mines. The first publication covered the results of a reconnaissance, carried out in 1910, of the formations in the region between Winnipeg and the Pacific Coast, which were likely to yield clay or shale deposits that might be of value in the ceramic arts. The report pointed out that there were not only extensive clay and shale formations but that some of them were of excellent quality and adapted to a variety of uses.

The new report deals with more extended investigation of this nature, and presents it on a formational rather than a geographical basis. It covers also the performance of a special series of tests on certain promising clays to determine their value for the manufacture of sewer-pipe and roofing-tile. (In addition, Mr. Keele made a somewhat detailed investigation of the preheating treatment as applied to Western Canada clays. This was outlined in *The Canadian Engineer* for February 12, 1914—page 311.) The sewer-pipe tests were carried out as follows:—

Samples were selected for special tests of those shales or clays which seemed to be of promise for pipe manufacture. These were moulded up to a very plastic mass and then pressed out through an annular die, giving a pipe whose outside diameter was 3 in., and internal diameter 2.5 in. Only those clays were used which flowed smoothly through the die, and these were cut up into 6-in. lengths.

After moulding, the pipes were dried and burned to cone 010, after which they were placed in the kiln of a sewer-pipe works, firing to cone 4.

It was to be expected that all of the samples tested might not yield the best results, as some would no doubt give better glazes when burned at a slightly different cone.

The clays used, together with the results obtained, were as follows:—

No. 1747.—Mixture of two parts Pierre shale from La-Rivière, and one part Niobrara shale from Leary, Man. This took a bright salt glaze, but not an exceptionally smooth one. This was undoubtedly due to the fact that the mixture was not ground fine enough, and that cone 4 is a trifle too high for these clays.

No. 1754.—Fireproofing clay from Coleridge, Alta. The salt glaze on this was fair, but the clay is hardly fire-resisting enough for successful salt glazing, even if its other physical properties were favorable to its use in sewer-pipe manufacture.

No. 1765.—Shale from Tofield, Alta., used in the proportions of 75% raw clay and 25% calcined clay, plus 2% salt to prevent cracking in air drying. This at cone 4 was much overfired, and it is doubtful if it would stand the heat required for salt glazing. If softened so at cone 4, that it was not stiff enough to hold its shape.

No. 1762.—Upper 7 ft. of shale from south bank of Lobstick River near Entwistle, Alta. The salt glaze on this was poor, and the clay itself is hardly refractory enough for making sewer-pipe.

Nos. 1805, 1806, and 1807.—Mixture of equal parts of these three clays, from the Dirt Hills, Sask. This mixture gave excellent results at cone 4. The pipe was straight, nicely vitrified, and the glaze smooth. The mixture should undoubtedly make a good sewer-pipe. The unglazed pieces showed some soluble salts, but not enough to interfere with the salt glaze.

No. 1817.—Mixture of two parts of top shale and one part under clay from Walton's mine, Minto, N.B. This took a good salt glaze, although cone 4 seemed a little too high, and better results would no doubt be obtained at cone 3. Care should be taken to grind this shale fine.

No. 1824.—Shale overlying sandstone, at Stonehaven, N.B. Like the preceding this developed a good salt glaze at cone 4, but was a trifle overfired. Cone 3 would be a better burning temperature for it. The clay should also be finely ground.

Roofing-Tile Tests.—A clay, in order to be useful for roofing-tile, should conform to certain requirements. These might be enumerated as follows: (1) suitable plasticity; (2) moderate shrinkage; (3) sufficient strength; (4) wide vitrification range; (5) development of preferably a red color in burning, which should be maintained without change over a range of several cones; (6) freedom from cracking and twisting in burning; (7) slow and slight warpage if burned unsupported.

It may not be difficult to find a clay which shows the proper development of some of these properties, but materials which are eminently desirable in all respects are more difficult to obtain.

In the manufacture of flat shingle tile and normal Spanish tile these slabs can be made by forcing a ribbon of clay through a slit-like die, and then cutting the ribbon up into proper lengths.

More complicated shapes, such as interlocking tile, are made by forcing a bar of clay through the die of a stiff-mud machine, this bar being then cut up into slabs which are given the proper shape by re-pressing in a plastic or steel mould.

One of the tests that may be applied to a roofing-tile clay in the laboratory, is the warpage test. This consists in moulding the clay or mixture of clays into thin strips 13 in. long, 1¼ in. wide, and ½ in. thick.

These are carefully dried, and then placed in the kiln resting on sharp edged fireclay supports, with a 10-in. span between the edges.

In the experiments these were burned at cones 010, 03, 05, and 1. The names of the clays tested and the results obtained in each case are given below.

In the testing of roofing tiles it has been advocated by some that their transverse strength when air dried should be determined,[1] but as shown by others,[2] the transverse strength of an air-dried clay stands in direct relation to its tensile strength, consequently it seems sufficient in describing these tests to give the latter.

Niobrara Shale from Leary, Man. (1636).—To this was added 25% of grog, consisting of calcined shale, to improve its working qualities. The bars had an average air shrinkage of 5.5%, and dried well without warping. The average tensile strength was 243 pds. per sq. in.

At cone 08 the fire shrinkage was 5.1, the sag 0.35 in., and absorption 12.2%. At cone 05 the fire shrinkage was 6%, the sag 0.58 in., and absorption 10.2%. At cone 1 the clay had sagged so as to give a deflection of 3½ in., and is to be regarded as over-fired. The clay is nearly steel hard at cone 08.

Clay from Dirt Hills, Alta.—This a grey shale lying at base of section in hill No. 2 (1647). The clay bars had an average air shrinkage of 7%, and an average tensile strength of 334 pds. per sq. in. It warped very slightly in drying.

At cone 08 the fire shrinkage was 1%, the sag was 0.08 in., and absorption, 15.5%. At cone 05 the fire

[1] Orton and Worcester, Ohio Geol. Surv.

[2] Ries and Allen, Trans. Amer. Ceram. Soc., vol. XII.

shrinkage was 2%, the sag 0.09 in., and absorption 14.7%. At cone 1 the fire shrinkage was 8%, the sag 1.37 in., and absorption 3.2%. The clay burns light red up to cone 05, but deepens considerably at cone 1.

Shale from Kilgard.—(1738).—The strips of this shale dried perfectly and had an air shrinkage of 4%. The average tensile strength was 114 pds. per sq. in. At cone 08 the fire shrinkage was 0%, the sag 0.08 in., and absorption 22.6%. At cone 05 the fire shrinkage was 1%, the sag 0.09 in., and absorption 17.3%. At cone 1 the fire shrinkage was 6.5%, the sag was 1.14 in., and absorption 7.3%. At cone 3 the fire shrinkage was 7%, the sag 1.57 in., and absorption 9%. The color after burning was a soft drab.

Shale over Coal at Minto, N.B.—(1817).—The shale dried well without warping. Its air shrinkage was 3.5%, and tensile strength 68 pds. per sq. in. At cone 08 the fire shrinkage was 2.5% and sag 0.28 in., with an absorption of 9%. At cone 05 the fire shrinkage was 4.5%, and the sag 0.60 in., with an absorption of 6.2%. The shale burns red, but the color is somewhat dull.

Surface Clay from Merritt, B.C.—With 25% sand added (1779A), the mixture dried without warping and had an air shrinkage of 7.5%, the tensile strength being 318 pds. per sq. in. At cone 08 the fire shrinkage was 9.5%, the sag zero, and absorption 13.2%. At cone 05 the fire shrinkage was 0.5, and the sag still zero, with an absorption of 13.2. The clay burned red but showed a tendency to scum, although this could be prevented.

Mixture of 3 Parts of Grey, Sandy Clay from Camrose, Alta., and 1 Part Shale from Gwynne, Alta.—(1801A).—This clay showed a tendency to buckle in drying, and its air shrinkage was 8%. The tensile strength of the mixture was 166 pds. per sq. in. At cone 08 the fire shrinkage was 0%, the sag 0.13 in., and absorption 17%. At cone 05, fire shrinkage still 0%, sag 0.16 in., and absorption 10.2%. The clay burns to a good red color.

Clay from Brickyard Site, Taber, Alta.—(1791).—This Clay dried without appreciable warping and had an air shrinkage of 8.6%. Its average tensile strength was 135 pds. per sq. in. At cone 08, the fire shrinkage was 2%, the total sag 0.14 in., and absorption 15.4%. At cone 05, the sag was 0.17 in., and the absorption 14.4%.

Lower Shale, South Side of Lobstick River, Near Entwistle.—(1763).—This shale dried well without warping, and had an air shrinkage of 6.0%. The average tensile strength was 114 pds. per sq. in. At cone 08, the shale had a fire shrinkage of 2.5%, a total sag of 0.18 in., and an absorption of 13.6%. At cone 05 the fire shrinkage was 3%, the total sag 0.24 in., and absorption 12%. At cone 1, the fire shrinkage was slightly greater, being 5%, the total sag 2.55 in., and absorption 0%. The shale burns to a light red color at the first two cones but is much darker at cone 1. It became steel hard at cone 05.

Sewer-pipe Shale East of Brickburn, Alta.—(1759).—This shale showed no distortion in drying, and had an air shrinkage of 6%, and the average tensile strength of 60 pds. per sq. in. At cone 08, it had a fire shrinkage of 1%, the total sag 0.09 in., and the absorption 12.3%. At cone 05, its fire shrinkage was 1.5%, total sag 0.16 in., and absorption 11.7%. At cone 1 the fire shrinkage was 6.5%, with a total sag of 1.42 in., and an absorption of 4.5%. The clay was steel hard at this last cone.

Shale from Valley of Bull's Head Creek, Alta.—(1757).—This warped slightly in drying and had an air shrinkage of 7%. Its tensile strength was probably high. At cone 08 the fire shrinkage amounted to 0.5%, with a total sag of 0.12 in., and an absorption of 10%. At cone 05 the fire shrinkage was 0.5%, the maximum sag, 0.18 in., and the absorption 9%. Its absorption at cone 1 was 2%. The clay burns red.

Fireproofing Clay, Coleridge, Alta.—(1754).—In drying this clay showed no tendency to warp. The air shrinkage was 4.6. The average tensile strength was 284 pds. per sq. in. At cone 08 the fire shrinkage was 0%, the total sag 0.06 in., and absorption 15.6%. At cone 05 the fire shrinkage was still 0, the total sag 0.07 in., and absorption 15.5%. At cone 1 it sags still more, but the exact amount was not measured.

Surface Clay from Hazel Brae, Clayburn, B.C.—(1741).—This clay dried well without warping, and had an air shrinkage of 6%. The average tensile strength was probably good, but was not tested. At cone 08 the fire shrinkage was 1%, the sag 0.08 in., and absorption 16%. At cone 05, the fire shrinkage was 1%, the sag 0.13 in., and absorption 16.4%. At cone 1 the clay was past vitrification, and had sagged badly. The clay burns to a good red color at the first two cones.

For convenience of comparison these properties are given in tabulated form in Table I.

RAINFALL, EVAPORATION AND RUNOFF IN MANITOBA.*

TWO main factors enter into the investigation of any possible power development—the head and flow available. While the first of these is obtainable through field survey and a knowledge of the extreme and average stages of river level, yet the second comprises an extensive study of the flow which, dependent on natural conditions, varies not only with the season and year, but also with the topography and character of the drainage area. Primarily all waters carried by rivers come from the rainfall or the melting of snow which has been precipitated during the winter months. Of this rainfall a portion evaporates, a portion enters the soil and is either absorbed by plant growth or by ground flow reaches the rivers or lakes, while the third portion finds its way into streams as surface flow or runoff.

Rainfall.—While the record of the runoff from a drainage area is of first importance in the question of power development, yet the rainfall or precipitation is also of extreme value, in that these latter records, if of a more extensive period than those of the runoff, would indicate the high and low range of flow which might be expected. In a like manner rainfall records in a drainage basin in which no discharge measurements are available can be used for the estimation of the flow based on the rainfall and runoff records of an adjacent area.

Throughout the southern portion of the province of Manitoba, rainfall records have been obtained by the Meteorological Bureau of the Marine and Fisheries Department of Canada, and these records are tabulated for the various stations in Fig. 1.

It is well known that the precipitation not only shows a variation from season to season, but also that a record extending over a short period of years is not sufficient to give the mean annual rainfall, but rather that for this means a period or cycle of long term should be considered. As the stations throughout the province at which long-term records have been obtained are not numerous, it is necessary to carry out some system of compensation for the shorter records of the adjacent stations. As is shown on the curves on Figs. 2 and 3, the records of the rainfall at the long-term stations shown separately for the eastern and western portions of the province have the same general features from period to period. Assuming that the intermediate stations of shorter terms will also range in a like manner from periods of heavy to those of light precipitation in the same years as at the long-term stations, the probable ratio of these short-term records to that of a long-term for the same station, has been based on the ratio of the precipitation at an adjacent long-term station during similar years, to the precipitation of the total period of the long-term station. As shown, the precipitation, together with the duration of the record, are given for various stations throughout the province. The ratio of all short-term records has been computed from the nearest long-term station as tabulated in the table, and a compensated annual mean for the station has been calculated. From these compensated results, the location of lines of equal precipitation has been determined. In the preparation of an isohyetal map of this district it has been necessary to use several records of very short period, but in the main, these records have been found to verify the lines of equal rainfall between the long-term stations.

Evaporation.—Of the tremendous losses due to evaporation from the ground surface very little is known. It is impossible to arrive as such losses by taking the difference between rainfall and runoff, as in this there would also be included the losses due to absorption by the soil and by vegetation, and again the rate of runoff does not depend altogether upon the rainfall. It is known, however, that a variation does occur in the evaporation depending upon many factors in which are comprised atmospheric conditions, geological and topographical features of drainage basin, together with the extent of forestration and vegetation.

Fig. 1.—Manitoba Rainfall Records.
(Assumption, 10 in. snow = 1 in. rainfall.)

A more complete study has been made of the evaporation from the water surface of lakes and rivers, the greatest use of such studies being in the investigation of storage and the losses which are likely to occur on such reservoirs through evaporation. That the losses on lake areas are very great and often of greater extent than precipitation is well known.

In connection with the investigation of the waterpowers on the Winnipeg River, and with the view to maximum efficiency in the development of powers thereon, it has been found necessary to consider and investigate

*Extracted from a report on the water powers of Manitoba, prepared by the Department of the Interior, Ottawa, for the Public Utilities Commission of Manitoba.

the possibilities of conserving the flood waters. Accordingly, very complete studies are being made of the storage possibilities of the immense lake areas of the the Lake of the Woods district. These studies have naturally included the securing of data with respect to evaporation, and on May 1st, 1913, an evaporation station, together with numerous instruments for the recording of all atmospheric phenomena which affect the extent of evaporation, was established on the Lake of the Woods in the vicinity of Keewatin, Ont.

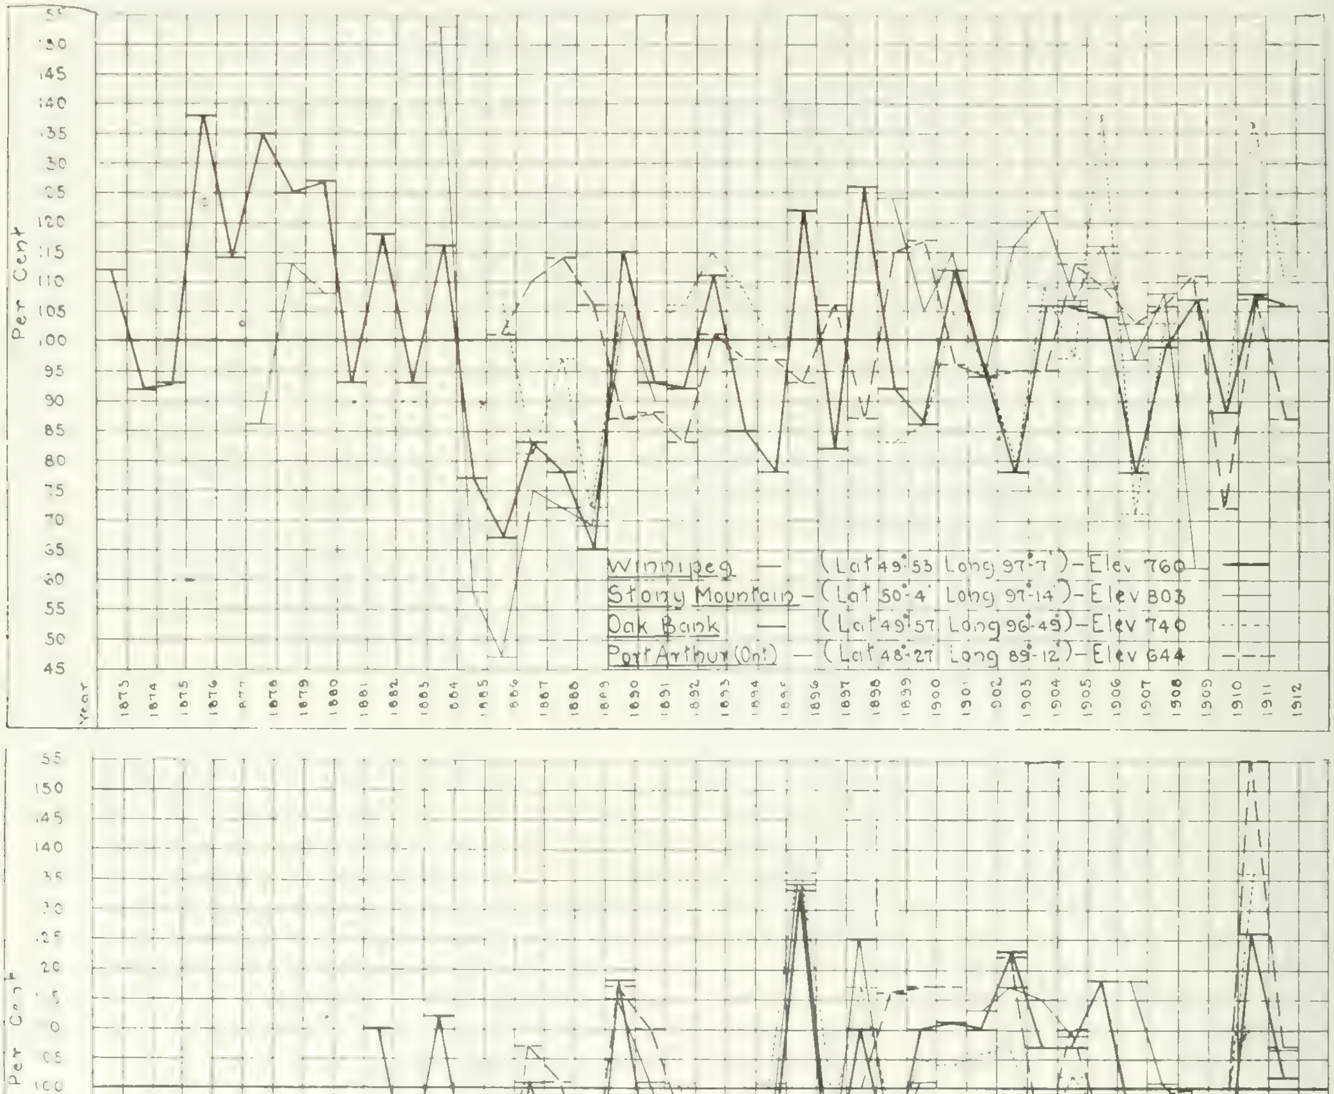

Fig. 2.—Curves Showing Relation of Precipitation at Long-term Stations in Manitoba.

Runoff.—It is readily seen that the extent of runoff or stream flow depends principally upon the depth of rainfall and the area of the basin drained, yet many other factors entering therein and of extreme importance comprise such as the geological formation and topographic features of the drainage area, whether of sloping land tending to give a rapid runoff, or of low-lying, swampy areas from which the flow is more or less uniform, and also dependent upon the extent of the growth of timber and vegetation together with numerous other factors.

While much can be gained from the studies of rainfall and evaporation and the physical features of a drainage area, yet the most accurate and reliable data with regard to runoff or stream flow is obtained by a sys

tematic gauging and metering of the flow of the stream to secure the continuous runoff and extending over sufficient time to obtain the extreme fluctuation. The runoff of any stream varies not only from season to season, but also to such an extent from year to year that the same conditions are not likely to occur on a river on any two successive years. Records for a cycle of at least seven years are, as a rule, necessary to cover the yearly variation to be anticipated.

Not only is the study of the runoff of streams of extreme importance in the investigations of power possibilities, but it is also of extreme value in the investigation of possible reclamation of low lands through drainage, or the reclamation of arid lands through irrigation. Such a study is also necessitated on many rivers where schemes for the betterment of navigation are proposed.

Manitoba Hydrographic Survey.—Previous to the year 1911, there had been no systematic or reliable gathering of data relating to the flow of the rivers in the province of Manitoba. Some few scattered discharge measurements had been made throughout the province, but not of sufficient extent to give information as to the continuous flow of any river as extending over various stages of their discharge. In the above year a systematic study of the power possibilities of the Winnipeg River was inaugurated by Mr. J. B. Challies, Superintendent of Water Power Branch, Department of the Interior of Canada. The field work, of which Mr. D. L. McLean was in charge, consisted of a detailed survey of the river and its power possibilities in Manitoba, and also included the establishment and maintenance of gauging stations on the river. This work, in the spring of 1912, was further enlarged so as to embrace a systematic study of the flow and power possibilities of all rivers throughout the province. For this extensive work, the Manitoba Hydrographic Survey was organized, with the appointment of Mr. D. L. McLean as Chief Engineer, the work still being carried on under the supervision of the Water Power Branch. Numerous gauging stations were established on the rivers and streams throughout the province, and since that time the gathering and compiling of the data has been vigorously carried on.

NORTHERN MANITOBA WATER POWERS.

During the year a report will likely be issued by the Commission of Conservation regarding water-powers in the three prairie provinces of the Dominion. Mr. L. G. Denis, one of the engineers of the Commission, has practically all the data in hand.

During the past year he spent 4 months on a reconnaissance trip through northern Manitoba. From Norway House his party descended the Hayes river to York Factory on Hudson Bay. He then ascended the Nelson river back to Norway House and thence to the mouth of the Berens river, on Lake Winnipeg. This river was investigated to the head of Little Grand rapids, after which the Pigeon river was descended, thereby returning to lake Winnipeg. The Dauphin river was likewise investigated.

The work entailed the taking of levels and discharge measurements, together with notes of the power possibilities along the rivers travelled. This information, added to that which had been previously collected on water-power resources of Saskatchewan, Alberta and southern Manitoba will constitute the substance of the new report.

TEST OF REINFORCED BRICKWORK

By Chas. H. Edmonds,
General Manager, The Reinforced Brickwork Company, Limited, Winnipeg, Man.

A NOTABLE test was conducted at Exhibition Park, Toronto, last fall to determine the maximum uniformly distributed load that could be supported without complete failure:—

1. By a cantilever.
2. By a beam built between two piers.

A solid 9-in. wall was built 3 ft. high, and supported by two brick piers so as to form a simple beam with 10 ft. clear span, and a cantilever beam 5 ft. clear length. The distance from the ground to the bottom of the wall was 3 ft. The two piers were 18 in. square, and were carried on a stone footing 3 x 3 x ½ ft. The vertical joints of every second course of the cantilever brickwork were built right at the pier. The cement mortar was a 3:1 mixture.

The reinforcing used was "HB," as supplied by the Reinforced Brickwork Company, Ltd., Winnipeg, two 2½-in. strips being used per course, (as the wall was 9-in. thick), and was run straight through beam, pier, and cantilever.

The work was allowed to dry out from the date of construction, August 20th, 1913, until October 9th, 1913, during which period the weather was dry and warm.

In order to obtain a uniformly distributed load, pig-iron was piled on the cantilever and beam, care being taken to keep the load built up squarely at the ends, and also to keep the top of the pile level, so that uneven loading conditions might be avoided. The idea followed out was to first load the cantilever to destruction. In order to give a fairly balanced condition, the beam was also loaded at the same time.

The first load was placed on the beam and cantilever on October 9th, 1913, the loading being applied until the beam carried 7,197 lbs., and the cantilever carried 2,519 lbs. On the following day the loading was continued. The following are total loads when work ceased at noon, Oct. 10th:—

Beam, 14,927 lbs.—Deflection, .07 inch.
Cantilever, 6,337 lbs.—Deflection, nil.

When loading was recommenced and had reached 13,063 lbs. the cantilever sheared off at the pier. Outside of a small hair crack on the tension side of the cantilever, and a very slight opening of about half a brick length of a mortar joint, the cantilever was intact. The bricks were broken across, no failure taking place horizontally along the mortar joints at the pier; or in other words, the bricks did not pull out on the tension side, or crush on the compression side of the cantilever. The vertical joints of every second course of the cantilever brickwork were built right at the pier. Had there been no vertical joints immediately at the pier, the ultimate load would undoubtedly have been greater.

Just after the cantilever failed, a slight fracture was noticed on the upper side of the beam. There is no doubt that, because of the cantilever shearing off at the pier, and the whole load falling vertically, the footing of the pier must have been given a severe shock. This, and the sudden releasing of the stress due to the cantilever being continuous, would naturally tend to produce fracture in the beam.

The beam was then further loaded until it was supporting a load of 36,190 lbs., and when this load was reached, it was noticed that the pile, having reached a considerable height, had a tendency to waver sideways. It was felt, in consequence, that further loading would

be carried on under rather dangerous conditions for the workmen. Loading was, therefore, stopped, and seven men were instructed to use a 2 x 12-in. plank, 15 ft. long, as a ram, and to deliver blows on the lower side of the beam at the centre. Seventeen blows were given, the result being a bad fracture, although the beam still held, and showed no inclination to fracture completely. The next blow, aimed at the central portion of the fractured material, caused ultimate failure.

Deflections.—Deflection readings were taken during part of the test. At failure, the cantilever showed a deflection of 0.125 in. The deflection of the beam, loaded with 16,561 lbs., and just after failure of the cantilever, was 0.101 in. Just previous to the load of 18,540 lbs. on the beam, the deflection was .115. At this load, a fracture occurred in the beam as explained above, and deflection readings were discontinued, as the fracture was thought to be more serious than subsequent loading proved.

Similar successful tests have been conducted in Calgary, Vancouver, and Winnipeg, and have a tendency to indicate that a modification of existing ideas with respect to the thickness of brick walls is needed. Building by-laws call for stated thicknesses, but in the cities of Montreal, Winnipeg, and Calgary, it has been conceded that owners and builders should be permitted to take advantage of such improved methods of construction, and the building by-laws have been amended whereby one may reduce the thickness of their walls by 4 in. to 9 in. by the adoption of a proper wire mesh reinforcement. Not only is there a saving of from 10 to 16 per cent. in the first cost, but the builder has the advantage of an additional amount of floor space which is of considerable yearly value to him.

To effectively reinforce a wall, there are certain conditions which must be fulfilled. If a strip of hoop iron is placed in the centre of a joint, and the wall subjected to lateral pressure, the position of the steel coincides with that of the neutral axis of the wall, and the steel will not become stressed. The greatest tension occurs at the outer edge, furtherest from the load, and in this case is carried by the joint—the steel only comes into action when the outer fibres of the mortar joint have failed, and the bond being destroyed, the steel is no longer protected from the weather.

In practice it is found, if using two strips of hoop iron placed near the edge of the wall, that failure will take place by shearing long before the full safe working stress of the steel is reached, partly because there is no connection between the compressive and tensile reinforcements, or no provision for shear, and partly because the metal is not sufficiently surrounded by the mortar to obtain proper adhesion. Consequently, for an effective system there are three fundamental points to be observed:—

(1) The reinforcement must be such that there are sufficient tensional members to take up the tension.

(2) Sufficient members to take up the shear.

(3) Reinforcement must be such that it is completely and easily surrounded by the mortar, both as regards adhesion and protection from weather and moisture.

The action of this new form of reinforcement is as follows:—

The reinforcement is firmly bedded in the mortar joint, and the tensional wires running the entire length and over the joints of support, form a continuous bond, and give to the mortar a power to resist tensional stresses which it does not ordinarily possess. The stresses in a wall, whether lateral or in the form of a load, tend to elongate these tensional members, and this is where the cross or lacing wires come into action. They form, with the tensional wires, a series of triangles which are surrounded and filled with the mortar of the joint. Any tendency towards elongation by the tensional wires would result in a closing action of these triangles, and, consequently, of the mortar inside them, but the mortar, being strong in compression, resists this closing action, and absorbs the stresses of the wire, with the final result that a compound force, much greater than the sum of the individual strengths of both mortar and steel, is developed. Practical tests have shown that the mortar joint is as strong as the brick, and the result is a brick wall which is a monolithic structure, not requiring continuous foundation, and immensely stronger than plain brickwork.

TRANSCONTINENTAL RAILWAY STEAMER FOR ST. LAWRENCE RIVER FERRY.

A CANADIAN car ferry and ice-breaking steamer, built by Cammell Laird, of Birkenhead, for the Transcontinental Railway Company of Canada, was launched on January 17th last. It is intended for service on the River St. Lawrence, between Quebec and Levis, and is a very interesting specimen of naval architecture. Its principal dimensions are, length 326 ft., beam 65 ft., with a draft of about 15 ft. The propelling machinery consists of 2 sets of triple expansion condensing engines, steam being supplied by 8 single-ended cylindrical boilers working under natural draught. An ice propeller of nickel steel, driven by a compound condensing engine, is fitted at the forward end of the vessel, which is built to Lloyds' special survey, and is arranged for the carriage of passenger and freight trains at all seasons of the year.

The trains are carried on a tidal deck, arranged above the main deck of the vessel, on three lengths of track, the length of each track being about 272 ft. The tidal deck rests on castings working up and down on 10 vertical lifting screws on each side, supported on columns, the columns being stayed by lattice buttresses against longitudinal transverse thrusts. The lifting screws are hung on ball bearings from the top, and are manipulated by means of worm-wheels, driven from horizontal shafting, which runs the length of the vessel on each side. The horizontal shafting is worked by bevel gearing from a four-cylinder, high-pressure engine of special design situated below the main deck. The gearing is arranged to lift the tidal deck, fully loaded with a train and locomotive weighing about 1,400 tons, at a rate of one foot per minute, to a height of about 20 ft., which enables the ferry to be loaded or unloaded at any state of tide. At each end of the tidal deck an adjustable hinged gangway is suspended, which allows for any change of trim or heel of ship due to unequal distribution of weights while taking the coaches, etc., on or off the vessel. Above the highest position of carriages on the tidal deck a promenade is arranged all round the vessel, with a bridge platform forward, from which all the operations of steering and manœuvring are directed. The boiler-rooms are arranged in wing compartments amidships, with the coal bunkers and the tidal deck engine-room between them. The main propelling engines are situated abaft the boiler-rooms, and the engine for the ice propeller is placed in the hold just abaft the fore peak bulkhead.

The vessel is fitted with electric light throughout, and electric gear is provided for raising and lowering the end gangways and for hauling the railway carriages on or off. Special arrangements are made for heating the carriages during transit. Double windlasses are fitted, one on each side, with slip-drum for mooring.

CONCRETE IN HIGHWAY WORK.

THE following remarks on the subject of concrete roads were made by Major W. W. Crosby, Chief Engineer of the Maryland Geological and Economic Survey, in the course of a discussion following a paper* read by Mr. Frank F. Rogers, State Highway Commissioner of Michigan, at the Philadelphia convention of the American Road Builders' Association:

While at present there seems to be a sort of a stampede, ably assisted, perhaps, by certain interests, toward the use of concrete for roads and streets, the speaker wishes to utilize this opportunity to express the opinion that the selection of concrete for such work may well be considered as divided into two main questions of great importance for proper determination.

The first of these questions is that of a necessity for rich concrete, or even for a concrete base itself, for the pavement or wearing surface itself—a condition by no means always existing or likely to exist during the life of the wearing surface. Many mistakes, it seems to the speaker, have been, and are being, made by the use of any concrete base or foundation where equal satisfaction at least and great economy would have been had by its omission or the substitution of a cheaper but, under the local conditions, an equally efficient foundation. It is to be understood here that the speaker believes that the use of concrete for the wearing surface itself, except in a few cases under peculiar conditions, is already proved impracticable, but for the sake of brevity the reasons for this conclusion will not be again expressed here.

The second of the questions referred to is made up of the old questions as to (a) the character of the wearing surface to be supplied on top of the concrete base or foundation, and (b) the thickness of such wearing surface.

As to (a) the character of the wearing surface to be built, little need be said at this moment for the purposes of the speaker.

The point which the speaker wishes to make at this time is under (b) the thickness of the wearing surface when the latter is bituminous in composition. Wearing surfaces composed of pitch compounds (bituminous materials, such as asphalts, tars, and oils) mixed either previously or *in situ* with sand, gravel or stone chips, have almost invariably proved unsatisfactory as carpets on concrete unless these carpets have been of more than a minimum thickness, dependent for expression in figures on local conditions, while those of sufficient thickness have proved satisfactory where their construction was proper under all the conditions.

The speaker thinks a reason for this difference in results between carpets identical except in thickness and for the failure of many too thin carpets comes from the fact that the thin carpets do not sufficiently absorb the shocks of traffic to prevent the disintegration and pulverization to a greater or less degree by such shocks of the surface of the concrete to which the carpet is applied. Hence, such carpets, lacking sufficient coherency in themselves and the preservation of a proper surface to which to maintain their adhesion, soon break up and disappear, first in spots and then altogether.

The surface of the concrete base naturally contains a great deal of mortar—an extremely friable substance, readily disintegrated under horses' feet and hard tires. If the effect of these is permitted to pass through the carpet and to reach the mortar, the latter soon becomes broken up and the adhesion of the carpet to a stable surface destroyed.

The same phenomena have been noticed by the speaker in the cases of macadam built of a soft, friable sandstone covered with a thin carpet, and their failure to occur has been equally noticeable where the thickness and character of the carpet has been sufficient to absorb the shocks referred to and to prevent disintegration of the friable materials underneath.

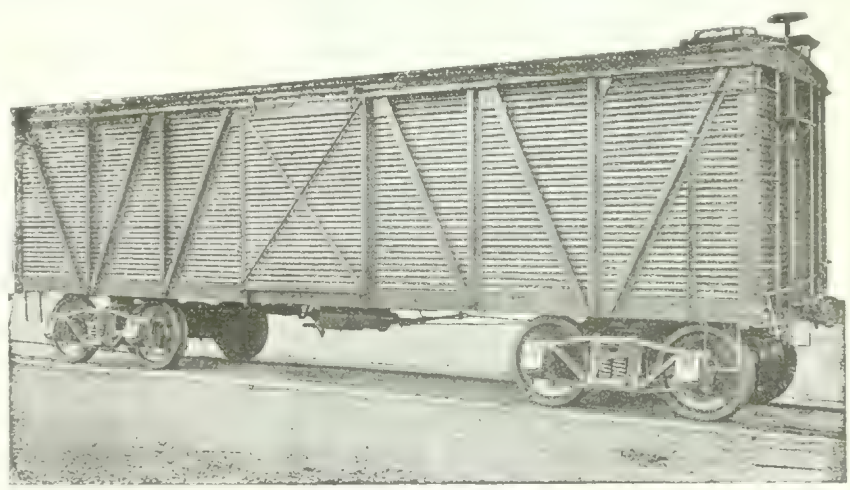
The speaker realizes the difficulties of thick carpets, but he feels they can be solved by proper methods, such as have been used in the case of a familiar form of carpet for city streets—the sheet asphalt pavement. He believes that further solution of the problem of adapting this pavement to country roads—by the substitution of a "paint coat" for the "binder course," for instance—is in sight.

*Published in *The Canadian Engineer* for November 13th, 1913.

ALL-METAL BOX CARS.

The illustration herewith shows an all-metal box car made by the American Car and Foundry Co. at Berwick, Pa., for use on the Central Railroad of Brazil, South America.

Owing to the conditions existing in that section it is necessary to use metal which would be anti-corrosive as the railroad alternates from a high altitude in mountains to very moist condition in the valleys and the extremes of altitude



and temperature are very conducive to corrosion. Toncan metal anti-corrosive sheets were used in corrugated form for the roof sides and ends. It is claimed that such a construction makes a perfectly fire-proof box car and in addition that the majority of methods whereby the car may be broken into and the contents molested are removed. A combination of corrugating and stamping was necessary in order to have the ends of the sheets flat at the corners of the car so that the heavy angle section could be riveted close up, thus preventing any leakage of contents. We are indebted to the Pedlar People of Oshawa, who are the Canadian agents for Toncan metal, for these interesting particulars of a new form of construction.

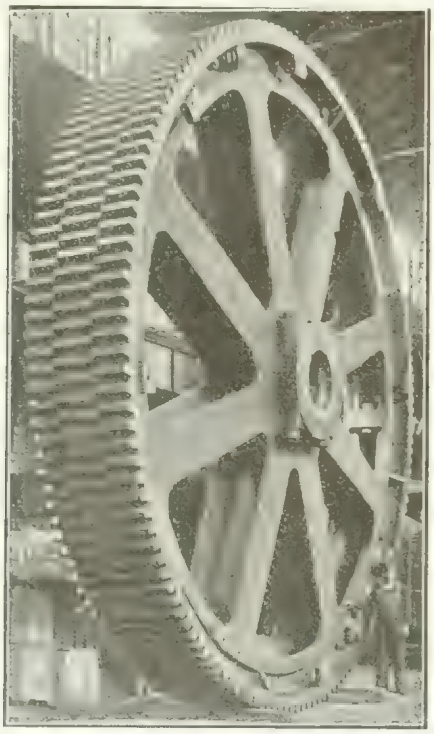
The Newfoundland Railway and Train Ferry Syndicate, Limited, a private company, has recently been granted authority to construct, equip, and operate a line of railway from the south-west arm of Green Bay to Humber Mouth, Bay of Islands.

A GIGANTIC STEEL GEAR.

A steel gear that is very unusual, and probably the largest of its kind ever manufactured, is being installed by the Inland Steel Company, of Chicago, to be used for driving a sheet mill. By the use of this gear and pinion a single-stage speed reduction is obtained from the motor to the mill.

This gear is 22 ft. 8 in. in diameter, with a 38-in. face and 5½-in. circular pitch. The mating pinion is 2 ft. 11 in. in diameter. There are 154 teeth in the gear and 20 teeth in the pinion.

The design varies from ordinary practice, because the teeth are staggered in three sections, as shown in the accompanying figure. On account of the axial motion to which the drive is subjected it was necessary to use a spur gear. Herringbone gears were not considered because of the unequal pressure that would be exerted on the side of the tooth face. The gears travel at the speed of 2,000 ft. per min. To meet the action of this high speed the gears were very



An Unusually Large Triple-staggered Toothed Steel Gear.

carefully cut, the teeth staggered and the drive arranged to run in an oil bath.

The machining of the gear is very interesting. All the teeth of the gear were cut on a planer, specially designed and built by the Mesta Machine Company, Pittsburg, the manufacturers of the gear. For large work they found the old-style crank-operated tools too yielding, and, consequently, originated their own planer. In this machine the tool is driven directly by a heavy lead screw, which in turn is operated by a variable-speed reversing motor.

The gear itself is built up of six parts. The gear centre, including the arms, etc., carries the central rim segments of teeth. The two halves of the gear are bolted together and the separate rims fastened to this by bolts running through the side of the central casting.

Starting with the rough casting, the operation of making such a gear will be followed. After annealing of the casting the joints at the hub and rim of the central portion of the gear were planed. These joints were then drilled, reamed, and the two halves bolted together. The wheel was then placed in the pit lathe, the gear centre turned down to the correct diameter, and the surface machined where the rim segments were to rest. The main gear was then taken from the lathe and the rim segments machined. Lugs were cast on these segments to aid in holding the work on the face-plate. One segment was bolted on the face plate and turned up. It was then reversed and the other side machined to size, and the segment turned to correct diameter. The surface of the segment to rest on the main gear was machined at this time.

The rims were next bolted securely to the main gear centre, with all the teeth in a line across the face of the gear, as shown in Fig. 2. The teeth were then planed, through the centre section and both side sections at the same time. The final cut was taken on the gear without removing the tool during the entire operation of cutting.

The mating pinion was machined in a way similar to that of the large gear. After the teeth were cut the bolts were taken out and the two side sections shifted on the centre section to give the proper stagger. This was done by using an indicating micrometer, so that the slightest variation from exact dimensions could be eliminated. After the stagger of the teeth of the pinion was set, the teeth of the large gear were set to match the pinion.

Holes were then drilled through both rims and the centre of the gear. These holes were reamed and machined bolts inserted.

The gear was then taken apart and shipped. Since the gear is built up of six parts, together with the fact that the parts were fitted together at the plant with machined bolts, before shipping, the installation will be very simple. It will not be necessary to disturb machinery already installed.

UNITED STATES COAL MINING INDUSTRY.

A production between 565,000,000 and 575,000,000 short tons of coal in the United States during 1913 is the official estimate of the United States Geological Survey, an increase over the record-breaking production of 1912 of 30,000,000 to 40,000,000 tons. These figures are given out by Edward W. Parker, coal statistician of the Survey, with the statement, however, that the coal mining industry in 1913 lacked any spectacular features, the increase, in other words, being normal and an index of the general industrial activity of the country. Of this increase about 4,500,000 tons was in the production of anthracite and the rest in the output of the bituminous coal mines.

The coal production in 1912 was 534,466,580 short tons, and the output in 1913 would probably have been somewhat in excess of 575,000,000 tons except for the general shortage of labor in the larger coal-producing states. This deficient labor supply was an important factor, however, in enabling operators to maintain prices, and it prevented an output in excess of market requirements, which would have added one more to numerous preceding years when prices were demoralized by an excessive supply. As it was, there was a slight advance in prices, compared with 1912.

The total coal production in 1900 was 269,684,000 tons.

Experiments described in the *Zeitschift des Vereines deutscher Ingenieure* on the flow of water indicate that a decrease in the flow in ascending pipes, and a low efficiency of certain types of pumps are due to the presence of air bubbles in the water. The velocity of the air bubbles increases with the amount of air flowing, and the relative velocity of the air with respect to the velocity of the water increases with the size of the bubbles.

COAST TO COAST.

London, Ont.—It has been announced that the Toronto-Windsor line of the C.P.R. is not to be double-tracked past London.

Toronto, Ont.—The station of the Marconi Wireless Telegraph Company, recently located at Toronto, is in operation.

New Hamburg, Ont.—The Boards of Trade of New Hamburg and Baden have appointed committees to act for those municipalities in the matter of hydro-radial service.

Winnipeg, Man.—The cash receipts of the Winnipeg light and power department in January will attain a record amount of between $85,000 and $90,000, according to the statement of Manager J. G. Glassco.

Yorkton, Sask.—When the new municipal electric power house is complete, and the two new 500 h.p. Diesel units have been installed, Yorkton's plant will have a capacity of 1,150 h.p. The lighting of the town also is to be extended, its main portion to be lighted by 5-light standards.

Moose Jaw, Sask.—Work on the C.N.R. bridge over the Moose Jaw Creek, the proposed entrance of the railway company into Moose Jaw, has ceased; and it is believed that this entrance will be abandoned in favor of running rights over the G.T.P. track into the city.

Vancouver, B.C.—The Imperial Oil Company has secured about 100 acres on Burrard Inlet, and will expend more than $500,000 in an oil-refining plant. Immediate work is to commence, it is understood. Plans for the improvement of the property include a wharf from 700 to 800 feet long.

Victoria, B.C.—The engineering branch of the Victoria civic service has at present in consideration the proposition of a civic-owned paving plant. The city engineer is securing information relative to cost, etc., pending the decision of the Canadian Mineral Rubber Company in connection with the completion of its paving contracts.

Toronto, Ont.—The recent statement of the Hon. Adam Beck shows construction plans for the Hydro-Electric Commission for 1914 entailing an expenditure of between two and three million dollars, and which, by the end of the year, will make the consumption of power considerably in excess of 80,000 h.p. The present monthly load is close to 55,000 h.p.

Granby, B.C.—During the week ending January 14, Granby smelter treated 22,480 tons of ore, 22,094 tons being from the Granby mines and 386 tons from other properties. The copper shipments amounted to 457,000 pounds. During the two weeks ending December 14, a total of 45,318 tons of ore were smelted and 773,000 pounds of blister copper were shipped.

Winnipeg, Man.—J. P. Gordon, assistant chief engineer for the Hudson Bay Railway, has reported that all the roads have been cut through as far as Manitou Rapids by the sub-contractors, McMillan Bros., and they expect to reach Kelly Rapids, within 100 miles of Nelson, before spring. The embankment of the road has been graded as far as mile 150 north of Le Pas.

Winnipeg, Man.—The construction of a steel bridge across the C.P.R. tracks at Salter Street, Winnipeg, instead of the proposed subway, is a proposal which is gaining favor among civic officials. It is believed that in a few years other passages connecting the north and south sections of the city will be necessary; and a system of bridges is considered preferable to subways, owing to the enormous cost of the latter.

Sarnia, Ont.—It is stated that Sarnia's new waterworks plant on the shore of Lake Huron, just above Point Edward will be completed in July, 1914. It will have a capacity of 6,000,000 gallons daily, and will have cost about $250,000. A feature of the system is that the current of the lake, which runs from 6 to 8 miles an hour at the point at which the plant is located, washes continuously the sand and germs of the filtration basin.

Saskatoon, Sask.—The operating railway mileage in the Province of Saskatchewan at the end of 1913, totalled 4,651 miles, an increase of 897 miles over 1912. This is almost double that of the province of Manitoba, whose railways were extended by 473 miles during 1913. In the Maritime Provinces the increase is merely twelve miles, i.e.:—2 miles in Nova Scotia and 10 miles in Prince Edward Island. New Brunswick remained stationary.

Vancouver, B.C.—The expenditure up to date upon the Point Grey partnership water main from Capilano has exceeded greatly the original estimate of cost. However, that estimate, which was $302,820 for the entire work, was made about five years ago. Up to the end of 1913, there had been expended $379,266 upon the construction; and it is believed that an expenditure of $50,000 will be necessary to complete the work.

Winnipeg, Man.—The gross earnings of the Winnipeg Electric Railway Company for 1913 were $4,078,694, as compared with $3,765,384 in 1912. Net quarterly dividends of $1,070,043, or a rate of 12 per cent. per annum, were paid, leaving a surplus of $185,461 to be added to the profit and loss account. This account at the end of 1913 attained the sum of $2,276,679; and the directors decided to place $1,000,000 of this to the credit of a reserve account; $375,000 in a suspense account; $901,679 remaining in the profit and loss account.

Victoria, B.C.—The award for tenders for piers Nos. 2 and 3, in connection with the Victoria breakwater and harbor works, is being watched for daily by local contractors. The date for reception of tenders was extended to admit of offers from old country firms. Pier No. 2 will be 1,000 feet on one side and 800 feet on the other, and will be 250 feet wide. Pier No. 3, which will be located 300 feet west of pier No. 2, will be 800 feet in length on either side and 250 feet in width.

Toronto, Ont.—A survey for an extension of the Temiskaming and Northern Ontario Railway has finally been made, which is considered feasible by the Provincial Government; and it is expected that construction will commence as early in the spring as the weather will allow. The survey extends from Elk Lake to Gowganda, and will connect by a continuous line of railway Sudbury, Gowganda, and Cochrane. It will make possible the construction of the line at but half the cost involved by the least expensive of the former routes surveyed.

Regina, Sask.—In addition to $160,000, which will be expended on Regina's light and power distribution system in 1914, there is provided $244,000 as capital expenditure on the new power house. Among the larger items which are included in this amount are $72,000 to complete the building, $11,000 to provide for the removal of 1,000 h.p. of boilers from the old power plant to the new, $22,000 for main switchboard and feeder regulator, two 125 k.w. exciters costing $12,000, machine shop equipment costing $6,500, oil filters and storage tanks costing $3,200, and lighting for plant costing $7,000.

St. Thomas, Ont.—The largest steel water structure of its kind has recently been completed at St. Thomas. It is a water tower to be used in connection with the city waterworks system to equalize the pressure and to afford a means

of water supply, should a break occur in the pumps or mains. It forms an integral portion of the improvements at present being carried out at the St. Thomas plant at a total cost of $100,000. The tower itself has been erected at a cost of $25,916, has a capacity of 500,000 gallons, a height of 144 feet, and is not only the largest in Canada, but the second largest in America.

Fredericton, N.B.—The adoption of the Fredericton Gas-light Company's proposition to supply electric power for the lighting of the city streets is likely to be accepted by the civic authorities. The company's proposal is to supply power at 3½ cents per kilowatt hour. The latest figures available show the consumption of current for running the street lighting service to be 105,000 kilowatts per annum, which at the quotation named would make the cost of power about $3,500 per annum. This would mean a considerable saving on the present expense of maintaining a civic plant; and would admit, it is considered, of extending the street lighting service, an improvement urgently needed.

Hamilton, Ont.—The entire plant of the Canada Steel Company, which was partly destroyed by fire in August, 1913, has been reconstructed and is ready for operation. The additions and parts rebuilt, including new machinery, have cost approximately $100,000. The company has erected a new brick and reinforced concrete roll and machine shop, 60 x 120 feet, completely equipped with all necessary tools for doing its own repair work; and a new shipping end to the plant, 60 x 250 feet, with crane runway the entire length, which handles all the finished material directly from the shears into the cars. It has also rebuilt the main mill building, has erected a new power house, installing a new 500 horse-power motor; and also an 8-inch mill.

Victoria, B.C.—Mr. H. E. Beasley, general superintendent of the E. and N. Railway Company, has reported that the Canada Bridge Company has completed the Big Qualicum steel span on the East Coast extension of the railway, and has removed its plant and men to Arbutus Canyon, which overlooks the Saanich Inlet. Since the concrete foundations have been ready for months, and some weeks ago the steel for this bridge was placed in readiness for putting together, it is expected that this structure will soon be erected. The E. and N. line will then have replaced all its timber trestles of any importance between Victoria and Wellington, with steel structures of splendid type.

Port Coquitlam, B.C.—The first ocean-going vessel built on the Fraser or Pitt rivers was successfully launched from the ways of the Coquitlam Shipbuilding and Marine Railway Company at the confluence of those rivers on January 31st. The schooner cost $70,000; and all the lumber which was used, except that of the keel and the spars, was logged off St. Mary's Heights, Coquitlam. She is 216 feet in length over all, with 41 feet beam, 14 feet depth of hold, 17 feet draught of water, 900 tons registered tonnage; and she has a lumber capacity of about 1,000,000 feet. She is iron-kneed and copper-fastened throughout, and all her iron work is galvanized. A shaft tunnel and engine-bed have been provided in case auxiliary engines are installed in the vessel.

Regina, Sask.—While other estimates still remain to be considered, up to date the Utilities and Works Committee of the Regina city council has authorized an expenditure of over $2,000,000 for civic works in 1914. An undertaking of great importance is the construction of a 5,000,000-gallon water storage basin at a cost of $140,000. This will be supplemented by two new pumps which are to be purchased, and together these will insure a water supply of 10,000,000 gallons for ordinary purposes and 10,000,000 gallons for fire purposes. Also this year, 12 miles of water mains and a similar mileage of domestic sewer mains will be laid; while the program of works and estimates also provides for sewage disposal, street railway extensions, construction of pavements and sidewalks, and electric light and power extension.

Fredericton, N.B.—A report has been furnished to the provincial government by Messrs. A. R. Gould and Ross Thompson, of the St. John and Quebec Railway Company, upon the progress made during the winter on the railway's bridge construction. Bridges have been completed at Centreville and Shogomoc; and at present a trestle is being erected at Eel River. From Centreville to Gagetown, all the bridges will have been built before spring, with the exception of one at Pokiok, which is in a small zone where steel is not laid. Material for all the structures is in process of manufacture and will be available as soon as required. The trestles still to be built are three below Fredericton, at Hartt Lake, Swan Creek, and Oromocto; and five above Fredericton, at Kelly's Creek, Long's Creek, Garden Creek, the Meduxuekeag, and the C.P.R. crossing at Woodstock.

New Westminster, B.C.—Mr. J. R. Freeman, consulting engineer for the Dominion Government, furnished recently a report to Mr. J. B. Challis, superintendent of the water power department, upon the Coquitlam dam, which has been built by the Vancouver Power Company, and especially upon the water supply of New Westminster, which is taken from above the dam. Mr. Freeman states that the present and prospective needs of New Westminster for water supply are amply provided for by the new intake tower and by the conduit leading from the tower to a point safely down stream from the limits of the dam; and that the work of the Vancouver Power Company has been of such a nature and scope as to tend to improve the quality of the water conveyed from Coquitlam lake to the city, as a result of the removal of stumps and decaying logs from the swampy margins at the lower end of Coquitlam lake, and also the very thorough work of felling, removing and burning the timber and brush within the range of the increased height of flowage by the new dam. Mr. Freeman concludes his observations on the purity of the water supply in the following words: "I know of no natural surface supply of water in the world that is superior to Coquitlam lake as a source for domestic supply, and I find that the company's work in dam-building has been so carried out as to conserve and improve this excellent quality."

Granby Bay, B.C.—One of the largest smelting plants in the Pacific northwest has been completed by the Granby Smelting Company, which has its headquarters at Grand Forks, B.C. The entire construction includes the smelter hydro-electric power plant, machine shops, and an electric railway system. It is located at Hidden Creek in the wilds of northern British Columbia, and has been erected at an approximate cost of $2,500,000. The purpose of the company, primarily, is to handle the output of its Hidden Creek copper mines, which have at present about 8,000,000 tons of ore in reserve, containing from 3 to 5 per cent. copper; but ores from properties owned by other companies and individuals will also be handled. The Granby Company has recently taken over the Midas group of claims and several other copper properties; but the plant, which will have a daily capacity of 2,000 tons, is expected to handle ore from all of these with facility. Operating expenses, also, will be greatly reduced by the proximity of the mines to the smelter. A connection afforded by 1½ miles of electric railway reduces transportation costs on the ore almost to a minimum. The report on the construction which has been furnished by Superintendent Williams, who is in charge of the construction states that there are 16 inches of snow at Hidden Creek, but that the buildings were all enclosed and roofed before the storms came, making possible completion of the work on schedule, the original estimate providing for blowing in the smelter furnaces between January 1 and February 1, 1914.

NEWS OF THE ENGINEERING SOCIETIES

Brief items relating to the activities of associations for men in engineering and closely allied practice. THE CANADIAN ENGINEER publishes, on page 94, a directory of such societies and their chief officials.

CANADIAN MEMBERS, INTERNATIONAL ELECTRICAL CONGRESS.

In connection with the International Electrical Congress to be held September 15th-18th, 1915, at San Francisco, Cal., U.S.A., during the Panama-Pacific Exposition, the following Canadian engineers have been appointed honorary members of the International committee on Congress organization: Dr. L. A. Herdt, (Vice-President I.E.C. and Local Honorary Secretary), McGill University, Montreal; Mr. Ormond Higman, Ottawa, Ont.; Mr. A. B. Lambe, Ottawa, Ont.; Prof. L. W. Gill, Queen's University, Kingston, Ont.

The proceedings of the International Electrical Congress will be divided into twelve sections, relating to the principal branches of electrical engineering, and it is expected that about 250 papers will be presented covering a wide range of topics. The San Francisco congress of 1915 will be held under the auspices of the American Institute of Electrical Engineers, and is authorized by the International Electrotechnical Commission and the Turin Electrical Congress of 1911. The International Electrotechnical Commission will meet at San Francisco during the week preceding the electrical congress.

TORONTO BRANCH, CAN. SOC. C.E.

The first of a series of monthly luncheons, inaugurated by the Toronto Branch of the Canadian Society of Civil Engineers, was held on February 11th, 1914. Over 75 of the local members were in attendance.

In the absence of Mr. A. F. Stewart, chairman of the branch, Major C. H. Mitchell presided. Among the speakers were Dean Galbraith, Mr. J. M. Clark, K.C., and Prof. C. R. Young.

Mr. Young, on behalf of the library committee of the branch, outlined the plans of that committee for the improvement and extension of the usefulness of the library. It was the ideal of the committee, as it is of the Engineers' Club of Toronto, to bring about a unification of the four separate libraries, now in the Club's rooms, into a large and valuable central technical library, accessible to any one who is a member of at least one of the technical societies contributing to it. Unfortunately, the energies of the Engineers' Club directorate were so much taken up with the problem of securing new quarters at the present time that little could be expected of it in the matter of library improvement for a year or two. However, the Canadian Society of Civil Engineers could do a great deal independently that would in no way interfere with what the Club might do, but would be complementary to it.

The policy of the library committee with respect to immediate extension was, first of all, to put on the shelves bound volumes of indispensable periodicals, especially the proceedings and transactions of the great engineering societies; and, secondly, a selection of the books most useful to the practising engineer. Duplication would, in general, be avoided, but might in a few cases be found desirable. In order to make the best possible choice of books, the opinions of many members of the Branch were being sought.

Several schemes for entending the usefulness of the library were outlined by the speaker. A monthly bulletin was suggested as a means of rousing the interest of the members; the privilege of keeping books out for a limited period appealed to the committee; engineering students in the University of Toronto would find the library of value, and the pointing out of this would be a service to them as well as an advantage to the Society through the incoming of many Student members; and, finally, the obtaining of exchange privileges with libraries in other cities would be a desirable arrangement for the members.

VANCOUVER BRANCH, CAN. SOC. C.E.

As announced in last week's issue, a paper, dealing with the construction of the section of the Canadian Northern transcontinental line between Yellowhead Pass and Vancouver, was read by Mr. J. V. Nimmo, before the Vancouver branch of the Canadian Society of Civil Engineers, on February 3rd. The paper was accompanied by 100 lantern views.

Mr. Nimmo, who has had an extended experience on railway work in India as well as on railway location and construction work in many provinces of the Dominion, dwelt upon his subject with detail, and in explaining the various passes across the several mountain chains and intervening valleys, he showed clearly the advantages attained by the Canadian Northern Railway in its route through the Yellowhead and down to the North Thompson via the Albreda Summit. In his remarks he paid tribute to the sagacity and foresight displayed by Sir Sanford Fleming, whose work in the '70's disclosed the desirability of the Yellowhead Pass. He went into details of grades and other technical features of interest to the engineering profession, indicating what the construction department had to contend with and what the completed railways would have to offer in advantages to the operating department.

Regarding construction, he said that the heaviest work was in the Fraser Canyon, where the heaviest mile cost $326,000, up to the point where it was ready for steel. Other portions of the canyon averaged $252,000 a mile in cost. Four years from the beginning of surveys would see the work completed.

In dealing with the locating and other engineering work, he referred to many of the difficulties encountered, and in the views shown indicated some of the perilous places where the engineers had to work, crawling along the faces of escarpments and overhanging cliffs. Notwithstanding this, only one engineer had lost his life in the work.

AMERICAN ROAD BUILDERS' ASSOCIATION—ANNUAL MEETING.

The annual meeting of the American Road Builders' Association for the election of officers was held at New York, Feb. 6th. At this meeting the following officers were elected:—

President—W. A. McLean, Toronto, Ont.
First Vice-President—Geo. W. Tillson, Brooklyn, N.Y.
Second Vice-President—A. W. Dean, Boston, Mass.
Third Vice-President—A. B. Fletcher, Sacramento, Cal.
Secretary—E. L. Powers, New York, N.Y.
Treasurer—W. W. Crosby, Baltimore, Md.

The following directors were appointed for three years:—

Samuel Hill, Seattle, Wash.; Paul D. Sargent, Augusta, Me.; A. H. Blanchard, New York; R. H. Gillespie, New York; Harold Parker, Worcester, Mass.; Fred. E. Ellis, Peabody, Mass.

The reports of the executive committee and the secretary showed a large gain in the active membership of the Association.

ASSOCIATION OF ONTARIO LAND SURVEYORS.

The following constitutes the list of successful candidates at the recent examinations for Ontario Land Surveyors.

Preliminary—T. N. Enright, Toronto, John F. LaPlant, Simcoe; William W. Perrie, Hamilton; Matthew Rae, Unionville; Henry W. Richardson, Hamilton; Leopold Wright, Toronto.

With supplemental—R. A. Cox, Collingwood; T. K. DeMorest, Ottawa; H. C. Mathers, Lambton Mills; W. R. Peck, Toronto.

Final examination—F. H. Muckleston, Toronto; N. B. MacRostie, Ottawa; S. G. McDougall, Ottawa; G. L. Berkeley, Toronto; Milton E. Crouch, Toronto; Karl Huffman, Toronto; P. A. Jackson, West Toronto; R. S. Kirkup, Fort William.

With supplemental—F. A. Bell, St. Thomas; J. H. McKnight, Simcoe; S. J. Pepler, Toronto; J. M. Riddell, Thessalon; J. R. Wood, Welland.

PERSONAL.

C. H. TOPP has been appointed engineer for the municipality of Esquimalt, B.C., to succeed W. E. Casey, resigned.

E. R. BINGHAM, O.L.S., has been appointed Corporation Surveyor for the city of Port Arthur, to succeed A. L. Russell, resigned.

E. H. VERNER, until recently engineer for the municipality of Coquitlam, B.C., has just been appointed city engineer of Port Coquitlam.

V. J. ELMONT, A. M. Can. Soc. C.E., of Montreal, is attending the annual meeting of the American Concrete Institute and the Cement Show in Chicago.

J. ANTONISEN, C.E., formerly City Engineer of Port Arthur and of Moose Jaw, has tendered his resignation to the Brandon Street Railway Company, for which he has acted as superintendent during the past year.

R. J. MACKENZIE, son of Sir William Mackenzie, will shortly assume the responsibilities of being active head of the lines of the Canadian Northern Railway between Lake Superior and the Pacific coast. He was recently appointed second vice-president.

H. W. DURHAM, M. Am. Soc. C.E., Chief Engineer in charge of highways, Borough of Manhattan, New York City, on February 9th delivered an illustrated lecture on "The Highways of Panama" before the Graduate Students in Highway Engineering at Columbia University.

ROBT. P. WEIR has recently been appointed district representative, with offices in the Traders Bank Building, Toronto, for the Cutter Company, of Philadelphia, Pa. Mr. Weir, a graduate in engineering of the University of Toronto, was previously with the Toronto Power Company, and also with the Toronto Hydro-Electric System.

GEORGE T. CLARK, former City Engineer of Saskatoon from 1909-1913, has been appointed construction manager for Western Pavers, Limited, having purchased considerable stock in the company. He will assume charge on March 1st. Chas. Curtis is president and sales manager of the company and Henry J. Keith is secretary-treasurer.

R. W. MILLS has been appointed head of a new branch of work in the Observatory at Toronto. This service is to supply rural communities with information respecting coming weather and its probable effect on crops, etc. The step was strongly advocated last fall by Mr. R. T. Stupart, Director of the Meteorological Service of Canada. Mr. Mills is a graduate of the University of Toronto.

IRON MINING IN ONTARIO IN 1913.

It has been shown by Mr. Thomas W. Gibson, Deputy Minister of Mines for the Ontario Government, that the production of pig iron in 1913 was about the same as in 1912—e.g., about 600,000 tons, which is valued at about $8,000,000. Five companies operate to produce this tonnage. They are located at Sault Ste. Marie, Midland, Deseronto, Hamilton and Port Colborne. A sixth furnace is being constructed at Parry Sound.

Five mines were worked during the year; the Helen and the Magpie located in the Michipicoten district, and owned by the Lake Superior Corporation; the Moose Mountain, the Bessemer, and the Belmont, the two latter being situated in Eastern Ontario. The ore of the Helen mine is hematite; of the Magpie, siderite, which is roasted to expel the carbonic acid and sulphur; and of the three others, the ore is magnetite, which undergoes concentration and sintering previous to shipment. The ore of the Bessemer is concentrated at Trenton, while the ore of the Belmont is shipped to the new blast furnace recently erected by the Buffalo Union Furnace Co. at Port Colborne. The total output of ore from these mines in 1913 was about 200,000 tons.

BACK COPIES WANTED.

One of our subscribers, anxious to bind his copies of *The Canadian Engineer*, lacks the following issues: Aug. 13th, 1909; Sept. 17th, 1909; Dec. 10th, 1909; Jan. 25th, 1912, and would be glad to pay 25 cents per copy for any of them. Will subscribers who happen to have these numbers, and who do not care to keep them, kindly send them in to this office in order that they are put into the hands of the party interested?

COMING MEETINGS.

CANADIAN MINING INSTITUTE.—Sixteenth Annual Meeting to be held at Windsor Hotel, Montreal, March 4th, 5th and 6th, 1914. Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

AMERICAN WATERWORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Deven, 47 Slate Street, Troy, N.Y.

CANADIAN AND INTERNATIONAL GOOD ROADS CONGRESS.—To be held in Montreal, May 18th to 23rd, 1914. Mr. G. A. McNamee, 909 New Birks Building, Montreal, General Secretary.

Mr. W. A. McLean of the Highways Department of the Ontario Government has shown in a recent report that, in the organized counties of Ontario, there are 50,000 miles of road. A classification would be approximately as follows:—

Trunks roads connecting the large towns and cities	2,500 miles
County or leading market roads	6,000 miles
(a) Main township roads	25,000 miles
(b) Secondary township roads	16,500 miles

The roads described as trunk roads are, with the exception of a few connecting links, among the most important of the county roads. Main township roads comprise principally the concession roads on which numerous farms front and which converge into and create the traffic of trunk or county roads. Secondary township roads include the little travelled connecting roads.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21283—January 28—Authorizing C.P.R. to construct, by means of a bridge, two tracks of the Cambellford, Lake Ont. and Western Ry. across Sidney Street, town of Trenton, at mileage 87.14 from Glen Tay.

21284—January 29—Relieving, for the present, the C.P.R. from provinding further protection at the crossing known as Keewatin Street, Winnipeg, Man., 400 feet west of mileage 3 on the Brandon Subdivision of said railway.

21285—January 29—Refusing application of G.T.R. for an order amending Order No. 14731, authorizing the G.T.R. to reconstruct Bridge No. 272, mileage 55.75, carrying the 13th Dist., Northern Div. of its railway across a farm road and stream on the west half of Lot No. 20, Con. 3, Tp. Albion, Ont.

21286—Approving revised location of Mount Royal Tunnel and Terminal Co.'s tunnel line from St. Antoine Street to the junction with its main line at Montreal, Que.; and rescinding Order No. 20899, November 27th, 1913.

21287—January 29—Amending Order No. 15440, September 15th, 1911, to provide that the Winnipeg Electric Ry. Co. be authorized to construct its tracks across the C.P.R. spur to the Winnipeg Industrial Exhibition alongside the Winnipeg Beach Branch of the C.P.R. on Selkirk Avenue, Winnipeg.

21288—January 31—Ordering protection by gates at the crossing of Prince Edward Street, by the G.T.R. and C.L.O. and W. Ry. at Brighton, Ont

21289—January 30—Ordering that no car or engine of the G.T.R. be left standing within 50 feet of the east side of the crossing of William Street, London, Ont., by G.T.R.

21290—January 29—Providing protection at the crossing of the first highway east of the station at Hastings by the G.T.R. in the Prov. of Ont.; watchman to be on duty from 7.30 a.m. to 7.30 p.m. daily, to be appointed by G.T.R.

21291—January 29—Authorizing the Municipal Council of the Corporation of Brampton, Ont., to open up Helstine Avenue across the track of the C.P.R. in the town of Brampton, Ont.

21292—January 29—Authorizing the C.P.R. to change the present grade crossing in the Don Road, Lot 2, Con. 3, east of Yonge Street, Tp. York, Ont. and to construct an additional track by means of a grade crossing, across said Don Road, at mileage 93.65, Toronto Subdivision.

21293—January 29—Approving plans No. 55070, December 15th, 1913, and No. 55365, showing overhead highway crossing at mileage 91.7 on the C.L.O. and W. Ry., Tp. Murray, Ont.

21294—January 30—Ordering the C.L.O. and W. Ry. to construct a farm crossing over its railway on the property of Smith A. Hendricks, in Lot 13, Con. 1, Tp. Murray, Ont.

21295—January 31——Extending the time for the completion of the farm crossing on R. V. Ditmars' property by the D.A. Railway, until May 1st, 1914, in the Co. Annapolis and Prov. of N.S.

21296—January 2—Approving location of the Kettle Valley Ry. Co.'s line from Coquihalla Summit to Hope, B.C., mileage 0 to mileage 39.42, subject to the condition that the 14 degree curve at mileage 3.2 be changed to a 12-degree curve.

21297—January 29—Authorizing the C.P.R. to take from the G.T.R. the lands required for right-of-way in the S. ½ of Lot 12, Con. 1, Tp. Hope, Co. Durham, Ont., at mileage 127.74 on the C.P.R.

21298—January 31—Authorizing the C.P.R. to construct a foot bridge over the repair tracks at North Transcona, Man Division.

General Order No. 120—February 3—Amending special tariffs of charges for detention of refrigerator cars when used for shipments of perishable freight, by eliminating the clauses therein relating to detention at the points of loading said cars.

21299—February 3—Authorizing the C.P.R. to re-construct Bridge 91.5, Toronto Subdivision, Ont. Div., Province of Ontario.

21300—February 2—Approving revised location of a portion of C.P.R. main line, Lake Superior Div., White River Subdivision, "as constructed," from mileage 29.00 to mileage 32.69 (Old Line), mileage 29.00 to mileage 32.49 (New Line), through Tps. 37 and 39, Province of Ont.

21301—January 27—Rescinding Order No. 20893, November 25, 1913, and rescinding Order 17358, August 27th, 1912, in so far as it relieves the C.P.R. from erecting and maintaining fences along portions of its right-of-way between Savona and Pennys.

21302—January 30—Authorizing the C.P.R. to construct, maintain and operate a branch line of railway or siding for the Northern Brick Co., from a point on the southwesterly limit of the C.P.R. at mileage 7.42, thence across public highway to and into the premises of the Northern Brick Company, situate in Lot 4, Con. 5, Tp. Waters, Ontario.

21303—January 30—Authorizing the Canada Southern Ry to connect its lines or tracks with the lines or tracks of the Niagara, St. Catharines and Toronto Ry. at the intersection or crossing of said railways near and west of Canada Southern Ry. Co.'s station at Welland, Ont.

21304—January 31—Extending the time within which the siding for the International Harvester Co. be completed, until the 31st May, 1913 by the G.T.R.

21305—January 31—Amending Order No. 20697, dated October 30th, 1913, by adding the following paragraph:—"4.—That the Grand Trunk Railway be, and it is hereby, authorized to construct the tracks of its branch line of railway crossing Gilkinson Street to and into the premises of the International Harvester Company of Canada, Limited (the said branch line having been authorized to be constructed under the said Order No. 19127, dated April 25th, 1913) across the tracks of the Hamilton Street Railway Company at the said point. the crossing to be protected by an interlocking plant, the details of which to be settled by an Engineer of the Board; and the cost of installing and maintaining said interlocking plant to be borne and paid by the G.T.R. Co."

21306, 21307 and 21308—February 2—Authorizing the Hydro-Electric Power Commission to erect transmission line across wires of the C.P.R. Telegraph on West Street, Goderich, Ont.; at Lots 17 and 18, Cons. 4 and 5, Tp. Winchester, Ont.; and on West Street, Goderich, Ont., respectively.

21309—February 2—Rescinding Orders of the Board Nos. 4406 and 5804, dated respectively 27th February, 1908 and 10th December, 1908, and granting G.T.R. leave to terminate lease described therein; and the G.T.R., its servants, agents, and workmen to re-enter and thereafter to have, possess and enjoy the said lands and premises freed and discharged from any further recognition or obeservance of the right, easement and privilege created by the said lease, or by the covenants therein contained.

21310—February 4—Authorizing the C.P.R. to construct, by means of a grade crossing, the tracks of its Ballast Pit Spur at La Fleche, across road allowances between the S.E. ¼ of Sec. 15, and the S.W. ¼ of Sec. 16; the N.E. ¼ 8, and the S.E. ¼ of 15; and the N.W. boundary of Sec. 6, at mileage 137.07 on the C.P.R. Weyburn-Stirling Branch, Sask.

21311—February 2—Authorizing the C.P.R. to construct, maintain and operate a branch line of railway or spur, for the Dominion Grocers, Limited, Moose Jaw, Sask., from a point on the northwesterly limit of right-of-way of C.P.R. main line, Alta. Div., thence across North Railway Street, and across sub-div. Lots 5 to 12 inclusive, Block 67, city of Medicine Hat, Alta.

21312—February 4—Authorizing the C.P.R. to construct the tracks of its Ballast Pit Spur at Meyronne, by means of a grade crossing, across the road allowance between the S.W. ¼ of Sec. 26, and the N.W. ¼ of Sec. 23, Tp. 8, Rge. 7, W. 3 M., at mileage 153.0, C.P.R., Weyburn Stirling Branch.

21313—February 5—Ordering the C.P.R. and G.T.R. to construct a subway under their double main line tracks at or near a point immediately west of the west end of passenger platform of the C.P.R. station at Ste. Anne de Bellevue, Que.

21314—February 4—Authorizing the C.N.R. to reduce its daily passenger service each way, excepting Sunday, to a tri-weekly passenger service each way, between Kindersley, in the Province of Saskatchewan and Hanna in the Prov. of Alta., from the present time until the 1st day of June, 1914.

21315—February 4—Declaring that land applied for by C.P.R. on French River Indian Reserve, Dist. Parry Sound, Ont., is required by Co. for railway purposes and is land which were it property of private owner could be taken without consent of owner.

21316—February 5—Extending until June 30th, 1914, the time within which C.P.R. complete branch line for J. D. Abbott, Balsam Lake, Tp. Eldon, Ont.

21317—February 5—Authorizing C.N.R. to divert public road in S.E. ¼ Sec. 29, Tp. 25, Rge. 20, W. 3 M., Sask., Alsask S.E. line. Rescinding Order No. 17042, July 16th, 1912, insofar as it authorizes crossing of highway between N.E. ¼ Sec. 20 and S.E. ¼ Sec. 29, said Tp.

21318—February 5—Approving and authorizing clearances of G.T.R. sidings serving premises of Canada Forge Co., Limited, Welland, Ont., for a period of six months from date of this Order, subject to provisions that Ry. Co. keep employees off top and sides of cars when operated over said sidings,, and that speed of trains be limited to rate not exceeding three miles an hour.

21319—January 28—Authorizing the C.N.O.R., subject to terms of resolution, to divert Jane Street at station 1094.32 in the town of North Bay, Ont.

21320—February 5—Relieving the C.P.R., for the present, from the speed limitation of ten miles an hour over the crossing of King Street, Virden, Man., subject to certain conditions.

21321—February 6—Authorizing the Toronto Eastern Ry. Co. and the Oshawa Electric Railway Co., to operate their trains and cars, for a period of six months from date of this Order, over the crossing to Carriage Factory, Oshawa, Ont.

21322—February 6—Authorizing the Toronto Eastern Ry. and the Oshawa Electric Ry. to operate their cars and trains over the crossing at Simcoe Street, Oshawa, Ont., for a period of six months from date of this Order.

21323—February 2—Authorizing the C.N.O.R. to construct, maintain and operate spur line of railway from its Montreal-Port Arthur line at the west boundary of the Tp. of Stafford, through the Tp. of Stafford and the town of Pembroke, with two branches at its northerly end in Pembroke, for the service of the Box Factory, the Steel Equipment Co., the Pembroke Lumber Co. and the local freight of the town and surrounding country; and to cross certain streets in Pembroke with the said spur line of railway.

21324—February 7—Authorizing B. C. Electric Ry. to operate cars and trains over crossing of Esquimalt and Nanaimo Ry. near Russell, B.C., authorized under Order No. 18733, February 18th, 1913.

21325—February 10—Rescinding Order No. 21286, January 29th, 1914. And amending Order No. 20899, November 27th, 1913, by adding clause:—"2. That approval herein granted be subject to condition that Applicant Co. acquire fee in and take all land of Mrs. H. B. Rainville, a property owner affected."

21326—February 10—Suspending, pending investigation by Board, Supplements Nos. 151 and 152 to G.T.R. tariff, C.R.C. No. E. 2552, published to take effect February 15th and 16th, respectively.

21327—February 10th—Suspending, pending investigation by Board, advanced rates published in Supplements Nos. 40 and 42 to C.P.R. tariff C.R.C. No. E. 2559, applying on building brick from Cooksville and Weston, Ont., to Toronto; and on gravel and building sand from Cooksville, Ont., to North Toronto, Parkdale and Toronto.

21328—February 10—Authorizing C.P.R. to construct spur for Winnipeg Paint and Glass Co., Limited, in D.G.S. 14, parish of Kildonan, Manitoba.

21329—February 6—Suspending, pending hearing and determination of matter by Board, increases in switching rates on sand, gravel and brick as from February 15th, 1914, notice of which is given in Supplements Nos. 19 and 20 to G.T.R. tariff C.R.C. No. E. 2677.

21330—February 9—Relieving C.P.R. from speed limitation of 15 miles an hour over portions of Weyburn-Stirling branch between mileages 0 and 52.2 on said branch line.

21331—February 9—Authorizing C.P.R. to construct spur extension for Ontario Stone Corporation, Limited, from end of existing spur for distance of 500 feet from B to C, as shown on plan, in Lot 10, Con. 4, Tp. North Orillia, Co. Simcoe, Ontario, at Uhtoff, mileage 68.4 on Ontario Division.

21332—February 4—Authorizing C.P.R. to take certain lands in Con. 3, Tp. Bathurst, Ont., for purposes of its railway, subject to certain conditions.

21333—February 9—Authorizing C.N.O.R. to construct across C.P.R. (Ottawa-Prescott Branch), near Hurdman's Bridge, Tp. Nepean, Ont., subject to and upon certain conditions.

21334—February 10—Rescinding Order No. 17477, September 12th, 1912, and 2. Directing that C.P.R., at its own expense, close present crossing and restore original crossing of Toronto and Sydenham Road, Tp. Holland, Ont., crossing to be constructed as nearly as practicable at right angles as shown in red on plan dated January 23rd, 1914.

21335—February 10—Authorizing C.P.R. to construct, by means of a bridge, across road allowance between Lots 22 and 23, Con. "A.," Tp. Hamilton, Co. Northumberland, Ont., at mileage 121.29 from Glen Tay.

21336—February 10—Authorizing C.P.R. to change present grade crossing in road allowance between Lots 13 and 14, Con. 3, in Tp. Trafalgar, Co. Halton, Ont., and to construct an additional track, by means of grade crossing, across said road allowance between Lots 13 and 14, mileage 31.77, London Subdivision, Ontario Division.

21337—January 29—Authorizing C.P.R. to construct, at grade, tracks of St. Mary's and Western Ontario Ry., along Thames Avenue, and across Park and Elgin Streets, town of St. Marys.

21338—February 10—Approving location C.P.R. station at Parsons, B.C., in S.E. ¼, Sec. 30-24-19, W. 5 M., mileage 22.80.

21339—December 3—Authorizing C.N.R. to construct spur for Dominion Gypsum Co. in Lot 13, River Lot 42, St. James, and to construct said spur across St. James Street, city of Winnipeg, Man., subject to and upon certain conditions.

21340—February 11—Relieving C.P.R. from speed limitation of 15 miles an hour over portion of Swift Current southeasterly branch line from point on main line near Swift Current, Sask., to Neville, Sask., mileage 27.5.

21341—February 10—Authorizing C.P.R. to construct, at grade, its Weyburn-Stirling Branch Line across twenty-two (22) highways, between mileages 277.78 and 298.07, province of Saskatchewan.

21342—February 11—Authorizing G.T.R. to reconstruct Bridge No. 240, carrying its railway over Bear Creek at Mile Post 212.07, near Powassan, 12th District.

21343—February 9—Authorizing C.N.R. to construct spur for Messrs. Nicholson and Blain, to serve Lot 112, Block 7, Hudson Bay Reserve, Edmonton, Alta., and to cross with such spur Peace Avenue, said city.

21344—February 11—Amending Order No. 20857, November 19th, 1913, to provide that G.T.P. Ry., construct forthwith a station and platform at Telkwa, B.C., not to be below the standard of a No. 1 A, B.R.C. station.

21345—February 11—Authorizing C.P.R. to reconstruct Bridge No. 18.71, Coronation Northwesterly Branch, over Battle River, Alta.

21346—February 11—Authorizing G.T.R. to reconstruct Bridge No. 234 over McCormick's Creek, mileage 43.30 on Fourth District, Montreal Division, Province of Quebec.

21347—February 10—Approving Supplement No. 3 to Express Classification for Canada No. 3, prescribing regulations for shipping of live poultry in coops.

21348—February 12—Authorizing the C.N.R. to open for the carriage of traffic its line of railway from Drumheller, mileage 314.7 to mileage 396.4, Alta.

21349—February 11—Ordering the Wabash Railroad Co. to stop its train No. 5 at Corinth, if flagged, on Tuesday, Thursday and Saturday of each week, for a period of 60 days from date of this Order.

21350—February 11—Ordering protection at the crossing of Bennett Avenue, Maisonneuve, by the C.N.Q. and the Montreal Terminal Rys., by means of a pair of gates, which are to be operated by day and night watchmen.

Volume 26. Toronto, Feb. 26, 1914 Contents of this issue on page 381

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

REPAIR OF INTAKE PIPE FOR CITY OF OTTAWA

RECLAIMING 40-INCH STEEL PIPE LINE LAID A QUARTER OF A CENTURY AGO IN THE OTTAWA RIVER—DESCRIPTION OF REMOVAL, REPAIR AND RELAYING.

By L. McLAREN HUNTER, A.M.I.C.E.,
City Engineer's Office, Ottawa.

At the present time, when Ottawa is in the throes of a discussion of the pure water question, a short description, with illustrations, of the reclamation of the old 40-in. steel intake pipe in the Ottawa River might prove of interest. This pipe, which has lain in the bed of the river for approximately a quarter of a century, has been disconnected, raised, towed ashore, repaired and is now being relaid.

Fig. 1.—A Length of Pipe Ready for Relaying

The work was in two sections, the first of which was from the main pumping station to the shore of Nepean Bay, a distance of over 2,000 ft., and the second from that point across Nepean Bay and the Ottawa River to Lemieux Island, a distance of approximately 3,200 ft.

The first section presented comparatively few difficulties, as the pipe had been laid in an open aqueduct. This was emptied, after having been closed, by means of a coffer-dam at the one end and stop logs at the other. The pipe was then disconnected and each length of about 45 ft. was tested. The old cast iron flanges were then cut off and the rivets and seams caulked where necessary.

After this had been done the pipes were placed in the desired alignment and riveted together by means of steel sleeves so as to form one continuous pipe from the pump-house to Nepean Bay. Two cast steel manholes were placed on this section, to give access to the pipe, if necessary.

In order to overcome the buoyancy which such pipes, when empty, have in water, a series of arched reinforced concrete beams were placed at approximately 25 ft. centres.

At the river end of the aqueduct the old stop-log house, found to be in a dangerous condition, is being replaced.

On the river section more difficulties have been encountered. The first step was to raise the pipes, which

No. 4 Tank on Shore.

Fig. 4.
Pump House and Portion of Aqueduct

averaged 50 ft. in length. They were covered with bark and logs (from the lumber mills nearby) to a depth of 3 or 4 ft. Owing to inaccessibility it was found impossible to secure the ordinary floats or scows for lifting

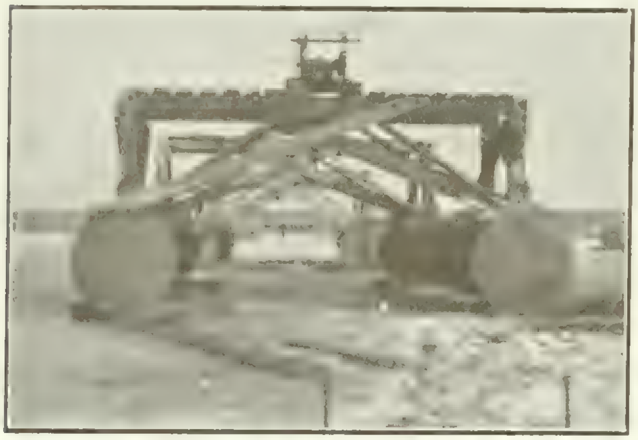

Fig. 5.—The Form of Pipe Float Used.

and taking the pipe ashore. The device used to overcome this difficulty was that of putting bulkheads on two lengths of pipe and erecting a gantry frame at either end, fitted with windlasses. This formed the pontoon

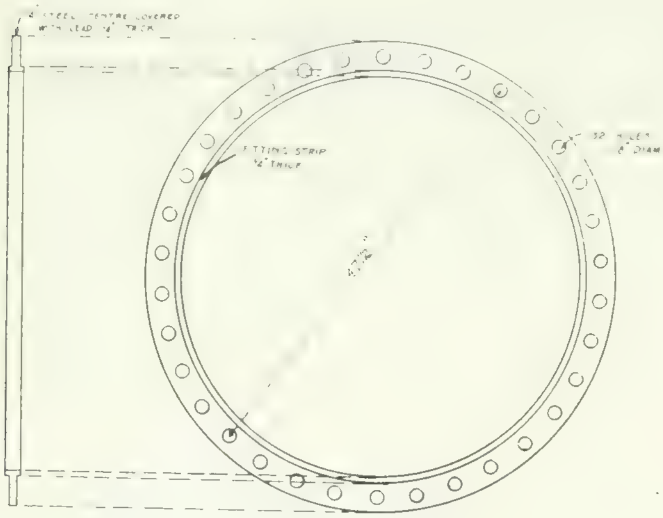

Fig. 6.—Style of Gasket.

illustrated in Fig. 5, 40 ft. in length, 15 ft. wide, with an open space between the pipes of 6 ft. It had a lifting capacity of approximately 13 tons.

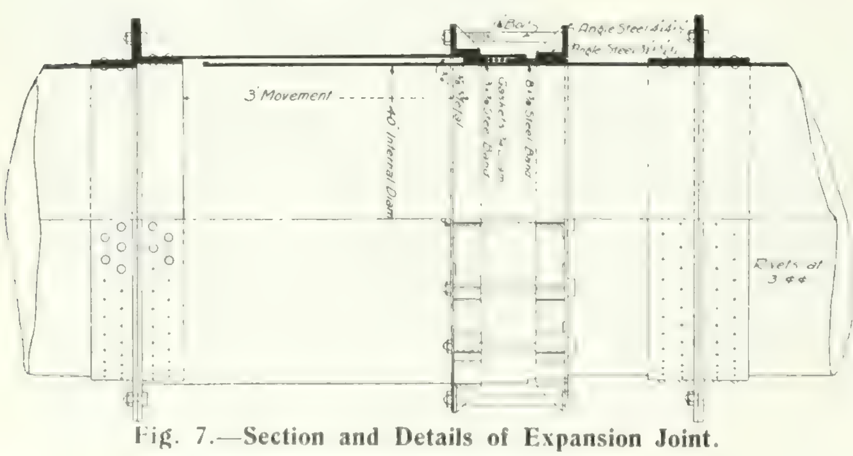

Fig. 7.—Section and Details of Expansion Joint.

This was then floated out over the old pipe, and divers disconnected the sections and placed a chain around either end. The pipes were then raised by the windlasses, emptied of water and a bulkhead put on each

Fig. 8.—Dredging Anchor Ice.

end. They were floated ashore to a temporary repairing yard and repairs similar to those in the aqueduct were effected.

Four of these pipes were connected together by means of alternate plain and special flexible corrugated slews giving an approximate length of 200 feet. (See Fig. 1.) Then curved flanges were riveted on each end

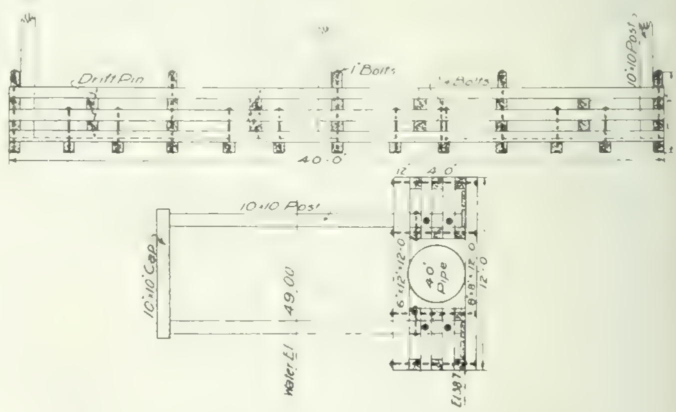

Fig. 9.—Form of Crib for Anchoring Pipes.

and the pipes tested to a pressure equal to twice the working head. All caulking and riveting was done by means of compressed air.

In the old pipe cast iron ball joints were used, but, not being found satisfactory, have been discarded altogether, and special angle pieces are being used instead.

There are 4 new piers being placed on the new pipe line, fitted with sluices. From piers Nos. 1 and 3 arrangements have been made to have cross connections between the 40- and 42-in. pipes. In the case of any accident one section of the pipe can thus be shut off while the remaining sections will be in commission. Pier No. 4, shown in Fig. 2 while under construction, from which there are four connections, was made up on shore before floating out and sinking into position. This necessitated breaking into the 42-in. pipe, a length of which was

lifted, cut to the proper length by the oxo-acetylene method, and then sunk and connected up. All such connections were made under water by divers. A slip joint fitted with graphite packing with a lead ring gasket was used in each connection. The type is illustrated in Fig. 6.

A special expansion joint with a free movement of 3 ft. is fixed on each section in the river. This will allow for any expansion or contraction, and will also be of great assistance at the pier connection. A section and detail drawing of this joint is shown in Fig. 7.

The new line is made so as to present an arch effect against the current in the river, thus relieving, as far as possible, the strain caused by anchor ice, etc.

Considering the length of time these pipes were in the river, their condition was marked, in that there was practically no corrosion. The buoyancy of the pipes in the river was overcome by means of wooden cribs, loaded with stone. Their general construction is illustrated in Fig. 9.

The work is being done by the Montreal firm of Loomis, McBean and Williams, at the contract price of $40,000, but with the extra work which has since been ordered this amount will be augmented by several thousand dollars.

The design and ideas of construction are those of Mr. Arch. Currie, city engineer of Ottawa, who recommended last July that the above procedure be undertaken, while Mr. A. N. Beer, assistant waterworks engineer, and Mr. Peter Carnochan are supervising the work of construction.

POWER DEVELOPMENT AT LONG LAKE, ALASKA.

LONG LAKE, which lies about two miles from the beach at an elevation of 727 ft., has an area of 3.1 square miles. It is situated near Speel River, between Ketchikan and Skagway, 35 miles southeast of Juneau, Alaska. A description of a project on foot to construct a 10,000-kw. plant appears in a recent issue of Western Engineering. Mr. E. P. Kennedy, assistant superintendent, Alaska Treadwell, G. M. Co., is the writer.

Water measurements for eight months and an estimate for the remaining four give a yearly run-off of 21,757 million cubic feet, and as the drainage area is taken at 32.4 square miles, the above run-off amounts to 24 ft., or an equalized yearly flow of 689 cu. ft. per second. The initial plant will use 300 sec.-ft., which is equivalent to a run-off of 10.4 ft. over an area of 32.4 square miles.

The power plant is to be situated near Second Lake, 2,000 ft. from and 535 ft. below Long Lake, and about 1½ miles from the beach. This plant will consist of two units, each of 5,000-kw. capacity and each to be direct connected to a water turbine utilizing 300 second-feet.

To be assured of a continuous flow of 300 sec.-ft., the lake will be drawn on by tapping with a tunnel or by a syphon to a depth of 12 ft., and the two spillways from the lake closed, thus raising the lake level 25 ft., giving an available storage of 37 ft. The cost of this power installation would be:

Power house with two 5,000-kw. units complete	$250,000
Pipe lines, two 60-inch with head-gates	93,594
Closing spillways from lake	10,000
Tapping lake	5,000
Contingencies and incidentals	3,000
Plant for construction	13,882
Total	$375,476

Or a capital cost of $37.54 per kilowatt or $27.95 per horse-power.

The cost of operating the above plant would be, per year:—

General expense	$ 6,000
Operating labor	6,000
Supplies, etc.	4,000
Total	$16,000
Operating cost per year per kilowatt	$1.60
Interest and depreciation, 8% on capital cost	3.00
Cost of kilowatt-year	4.60
Cost of horse-power-year	3.43

To be assured of a yearly average of 10,000 kw., the generators should be run at 25% above normal capacity for 6 months of the year while there is a large excess of water, and thus provide for unforeseen shut-downs.

Surveyed lake area is 3.1 square miles, or 86,423,040 sq. ft., requiring 20 ft. in depth at this area to provide for the required storage.

This storage is obtained by raising the lake level 25 ft. and drawing on the lake 12 ft. The increased area obtained by raising the lake will make up for the decreased area by drawing the lake and also provide sufficient storage below the 2 ft. of ice.

Power estimate is based on a pipe-line loss of 1%, water-wheel efficiency of 82%, generator efficiency of 93%; total efficiency of 75% from the water. Three hundred second-feet under 542-ft. head at 75% will generate 10,320 kilowatts.

From flow measurements the following figures are obtained:—

	Measured flow.	Required flow for 300 sec.-ft.	From storage.
January	324,187,200	803,520,000	479,332,800
February	283,046,400	725,760,000	442,713,600
March	374,976,000	803,520,000	424,544,000
April	352,512,000	777,600,000	425,088,000

Total						666,530

Velocity when carrying 300 sec.-ft., 8 ft. per second; loss per 100 ft., 0.225.

Weight of two lines, 1,337,060 lb.; and estimated cost erected is 7c. per pound.

The steel of which the above pipe is made will have an ultimate tensile strength of 60,000 lb. per square inch. Thickness of pipe is figured from the formula:

$$\frac{\text{Diam. in inches} \times \text{pounds pressure}}{2 \times 10{,}000}$$

which takes care of the efficiency of joints and allows a sufficient factor of safety. The weight of above pipe is obtained from the formula: weight in pounds per foot (12.5 times diameter in inches times thickness in inches) plus 10 lb. This weight takes care of laps, rivets, asphaltum, paint, etc.

RECLAMATION PROJECT IN CHINA.

It has been announced that the Chinese Government has authorized the issue of $20,000,000 of bonds for the future prevention of floods in the Huai River Valley in China, and that the J. G. White Engineering Corporation has been designated to undertake the construction of the works.

The project will require approximately six years to complete, and employment will be given to about 100,000 men. It will involve dredging the channel of the river and the Grand Canal; constructing dams and reservoirs to keep the Huai in its proper course, and to impound its surplus water and divert the streams flowing into the Huai, which, at the time of floods, greatly increase its overflow. The Huai River, for the greater part of its length, flows between banks that are elevated above the surrounding country, and in times past the river in overflowing its banks, has changed the geography of an entire province over night. During one of the flood periods, the Yellow River, which is a tributary to the Huai, switched the location of its mouth a distance of about 700 miles. Government records show that floods in this district have reduced the average number of crops from two in one year to two in five years.

Maps have been published recently at Tacoma, Wash., which shows that surveys for three railroads, starting at Grays Harbor and extending north into Olympic Peninsula, have been completed, the roads varying from about 110 to 125 miles in length. One survey was made for the Northern Pacific, one for the Union Pacific and one for the Chicago, Milwaukee and St. Paul Railway. The three surveys all parallel the coast and all touch the Quiniault Reservation.

PLANT, HIGHWAY AND LABORATORY INSPECTION OF BITUMINOUS MATERIALS.*

By Francis P. Smith, Ph.B.,
Consulting Paving Engineer, New York City.

BROADLY speaking, a comprehensive system of inspection of bituminous materials and pavements or roadways made from them may be subdivided as follows:—

1. Preliminary inspection of raw materials;
2. Inspection of materials and processes during construction work;
3. Inspection of finished work.

Preliminary Inspection of Raw Materials.—These are, or should be, assembled by the contractor sufficiently in advance of starting the work to permit of their being tested. They usually consist of refined asphalt or asphalt cement; residuum flux; crushed stone or gravel; sand; and filler. All of these materials should be sampled from deliveries actually on hand on the work. Except where the manufacture of the material is inspected at the refinery, this rule should never be departed from in the case of the bituminous materials themselves; i.e., the refined asphalt or asphalt cement and the residuum flux. In the case of the materials which constitute the mineral aggregate of the pavement or roadway, contractors are often unable to judge themselves whether or not a particular material passes the requirements of the specifications and before placing their order for them they frequently submit samples obtained from different dealers for approval. In the case of crushed stone or gravel, these samples usually fairly represent the kind of material which will be delivered. This is also true in the case of filler. With sands, however, samples submitted by the dealers frequently vary very greatly from actual deliveries. It often happens that the selection of sand has not been given sufficient attention or has been deferred until the last moment, with the result that no really suitable samples are submitted. In such cases it is frequently to the interest of all parties concerned, although perhaps not strictly the duty of the inspector, to personally visit and examine available sources of sand in the immediate neighborhood. In this way much better material may often be obtained than would otherwise be the case.

Sand and gravel banks are usually stratified and where the deposit has been made from comparatively still water the lower stratas will usually contain coarser material than the upper stratas. In every case the sand dealer should be impressed with the necessity of carefully stripping the top of the bank to remove deposits of clay, loam, etc., as this material is undesirable and will usually ball up in the heating drums. Where the stratas vary considerably and can not be dug separately, it will be necessary to take an average sample of the run of the face of the bank in order to determine what will be the composition and character of the average output of the deposit. In certain cases it is necessary to select definite stratas and have all the sand taken from them. In other cases the sand is dredged from river or creek beds and in order to obtain a satisfactory supply, it is sometimes necessary to go on board a dredge with a set of screens and a sand scale and sample the sand obtained from

*Public lecture delivered before the graduate students in Highway Engineering, at Columbia University on January 20th, 1914.

various portions of the river bed. When prospecting outlying country for available sand deposits, a small frying pan is a very convenient utensil to carry, together with the sand sieves and scales. By means of it, samples of sand taken from various pits can be dried over a small fire and sifted on the spot, which avoids the necessity of carefully marking them for identification and taking a lot of samples back to the laboratory or office. When securing samples of materials for examination, these should be carefully selected so that they really represent an average of the materials. The quantities necessary for examination are about as follows:

Refined asphalt or asphalt cement....	1 pound
Residuum flux	½ to 1 quart
Crushed stone or gravel	1 to 3 pounds
Sand	1 pound
Filler	½ pound

When these are sent to a central testing laboratory they should be plainly marked with the following information:

Kind of material,
Date material was received at paving yard,
Date when sample was sent,
Quantity of material represented by sample,
Name of manufacturer or from whom purchased,
Name of paving contractor who is to use the material represented by the samples,
Name of city or town in which work is being done.

Method of Obtaining Samples.

Refined Asphalt.—This is usually shipped in barrels containing from 300 to 500 pounds each. It will depend on circumstances and the quantity of material on hand how many barrels should be examined. Where the barrels are marked with the dates or batch numbers and different batches are represented, it will usually be sufficient to take a single sample from each batch. Certain specifications give a permissible limit of variation in the penetration or consistency of different shipments of asphalt. In such cases it will be necessary to test for penetration a sample from each batch number, in which case all of the samples taken must be kept separate. Where no such provision is included in the specifications and the inspector is assured from his past experience that the particular manufacturer from whom the material was purchased is careful in his output, a fewer number of samples will be necessary than under other circumstances. In some cases an average sample made up of different samples taken from the requisite number of barrels will be all that is required. The packages or barrels used by different manufacturers are very often characteristic of the product, and this is also true of the odor and general appearance of the material. A qualified inspector will often be able to determine from observation whether or not the contractor's statement as to the source of the material which he intends to use is correct. In taking the samples, material should be selected which is free from dirt, etc., and which has not been exposed to the air. In other words, a piece of refined asphalt should not be taken from the top or immediately adjacent to the outside of the barrel.

Asphalt Cement.—This is quite often shipped in tank cars and in such cases a single sample taken, preferably after the contents of the car have been melted, will be sufficient.

Crushed Stone or Gravel.—Various samples from different portions of the pile should be taken and mixed together, and from the mixed portion sufficient should be selected for test. It is always advisable to dig into the surface of the pile a little way in order to get material which has not been exposed to the atmosphere and which possibly has lost through the action of wind or rain, or both, a considerable portion of its fine material.

Sand.—It is almost impossible to secure a fairly representative sample of dry sand, as the coarser grains have a different angle of flow from the finer grains and are found in different portions of the pile. The pile should always therefore be dug into some distance below the surface until damp sand is reached. After sampling the pile in this way in a number of places, the samples so obtained should be mixed together and sufficient taken for test from the mixed lot.

Filler.—This is usually Portland cement or finely ground lime dust, and comes in bags. No particular difficulty attends the sampling of this material, but a sufficient number of bags should be opened and samples obtained from them and mixed together in order that the sample sent for test shall correctly represent the average quality of the material.

The examination of the samples so obtained is usually conducted in accordance with detailed specifications. As these vary somewhat in their requirements, it is impossible to lay down a general rule which will cover the examination of raw materials for paving work. After the materials have been examined in the laboratory and found to be suitable for the work and in accordance with the specifications, the inspector can frequently be of great service in suggesting to the contractor the best formula to use. All paving specifications allow considerable leeway as to the composition of the mineral aggregate and the percentage of bitumen required in the mixture. Sometimes the decision lies entirely with the engineer on the work and where he is fully competent to decide these questions it should, of course, be left to him. As the contractor usually has to assume a guarantee on the completed work, he naturally feels that he should be consulted as to the formula used. Sometimes his desire to reduce the cost of his work will lead him to employ a formula which, while complying with the minimum requirements of the specifications, is really not suited to the work in hand. Whenever possible, cooperation between the inspector and the contractor will always secure the best results and a little tact used in this connection will usually be all that is required. It frequently happens that two or more kinds of sand or stone have to be mixed together in order to secure a suitable mineral aggregate. Many contractors are exceedingly careless in keeping their different kinds of materials separated. Unless this is done it is impossible to make a uniform mixture of the various materials and provision for the piling in separate and convenient places of the different materials should always be made before they are delivered. This is a very important consideration and lack of attention to it will not only hamper the execution of the work but its quality as well. It is necessary and advisable to impress on all the dealers furnishing raw materials the necessity of a uniform supply. This is particularly the case with sand dealers, who are often small men who have been accustomed to supply sand to builders and parties requiring it in small amounts. Almost invariably, men of this type will not realize the great difference which a, to them, small variation in the mesh composition of the sand will make to the paving contractor.

Inspection of Materials and Processes During Construction Work.—These may be sub-divided into plant and street inspection.

Plant Inspection. During the progress of the work additional quantities of raw materials will from time to time be delivered to the contractor's plant. These should be sampled and examined in the manner previously described for the preliminary inspection of raw materials and no deliveries should be used in construction work until after they have been examined and tested and found to be in accordance with the requirements of the specifications. Owing to delays in the arrival of shipments this may at times be difficult, if not impossible, but in such cases, if it is inadvisable to shut down the work temporarily, the inspector should make all the tests possible at the plant in order to convince himself that the materials are suitable for the work. If he is able to determine definitely that they are unsuitable, they should, of course, be rejected and work shut down until other suitable material is available. At times it may be necessary for him to assume the responsibility of passing the materials and permitting their use pending an authoritative report from the central testing laboratory. Sometimes there will be but little risk in doing this; under other circumstances it may be advisable to permit the contractor to proceed with his work with the distinct understanding that if the materials are found not to comply with the requirements of the specifications he will take it up. Such an arrangement should only be made in writing and with the consent of the resident or supervising engineer. Where sand is delivered by wagonload, it will usually be sufficient to take an average sample of the day's deliveries and test it. Where the sand is delivered by rail or barge, the contents of each car or barge should be tested, if possible before unloading it. These instructions apply also to stone and gravel. It is so extremely important that deliveries of various grades of stone, sand and gravel should be kept separate that the speaker again wishes to emphasize this point.

Generally speaking, the processes involved in the manufacture at the plant of bituminous paving material are:—

Preliminary mixing and heating of the mineral aggregate.

Preparation and heating of the asphalt cement or bituminous binder.

Mixing of the heated mineral aggregate with the hot asphalt cement or bituminous binder.

Preliminary Mixing and Heating of the Mineral Aggregate.—The proportions in which the various constituents of the mineral aggregate are to be mixed will, of course, depend upon their character and the specifications under which the work is being carried on. The method of mixing the different ingredients depends somewhat upon the feeding arrangements at the plant and the disposition of the raw materials. In certain large plants the raw materials are stored in bins. In some instances these bins have automatic feeding devices which deliver the contents of the bins upon a conveyer belt. In such cases the automatic delivery devices should be set at the proper points and during their operation should be watched from time to time in order to see that they are delivering the desired quantity of material. With certain mixtures a mere inspection of the mixed aggregate as it is being fed to the heating drums will enable the inspector to roughly determine whether or not the proportions are being adhered to. With other types of mixtures this is very difficult to regulate by observation at this point. In the majority of instances, plants are not provided with storage bins of the type previously described and the materials are dumped in piles on the ground. These piles are usually arranged so that the material from them can be easily conveyed to the feeding device for the heating drums by means of wheelbarrows or horse slips. Where the mixture consists of sand and stone of various sizes, with a considerable proportion of stone, it is advisable to have the mixture made in a pile adjacent to the feeding device. This can frequently be done satisfactorily by having the requisite number of wheelbarrowfuls of the various ingredients dumped on a certain spot, this pile to be roughly mixed by shovels and then shovelled over into the feeding device. Where a simple mixing of two grades of sand is required, this can frequently be done satisfactorily by building a small box or boot around the bottom of the cold sand elevator and having the fine sand placed on one side and the coarse sand on the other side. One man on each of the two sand piles can then shovel the material into the box above mentioned in accordance with the mixing formula determined upon. Assuming that two parts of coarse sand were required to one part of fine sand, the man on the coarse sand pile would have to throw two shovelfuls of sand into the box to every one shovelful thrown by the man on the fine sand pile. The feeding of the sand thus thrown into the box would be attended to by a third man, who would feed it to the buckets of the elevator by means of a hoe or shovel. Usually the fireman who is in charge of the firing of the heating drums is able to supervise the operation of the feeding gang and see that they feed a properly proportioned mineral aggregate. In mixtures of sand and large sized stone there is liable to be a certain amount of segregation of the material in its passage through the heating drums. Certain plants are provided with an overheat screen to separate the heated material after is comes from the drums into the various sizes and distribute them into different bins. The material contained in these bins is then drawn out into the measuring box in definite proportions according to weight. This, of course, is the most accurate method of making mixtures involving the use of a large proportion of relatively coarse stone.

The function of the heating drums is to dry and heat the mineral aggregate. Unless ample air circulation is provided for to carry off the moisture in the shape of steam, the drying will not be effectively conducted. It is essential to regulate the rate of feed and the temperature of the heating drums so that the mineral aggregate delivered from them will be dry and at the proper temperature. This operation is usually in charge of the fireman for the heating drums. The most modern plants are provided with a pyrometer inserted in the delivery chute from the heating drums. This pyrometer has a plain or recording dial which is placed at the feeding end of the drums, where it is under the observation of the drum fireman. This makes it easy for him to regulate his fires and the rate of feeding necessary to secure the desired results. Where no pyrometer is inserted, it is necessary for him to test the temperature of the material issuing from the delivery end of the hot sand drums from time to time, as often as may be required in order to produce satisfactory results. It is a comparatively simple matter to take the temperature of heated sand, but where the mineral aggregate consists of large stone particles, it is a much more difficult and unsatisfactory operation. Certain types of mixing plants are so constructed that it is very difficult to obtain samples of the hot mineral aggregate before it is mixed with the asphalt cement or bituminous binder. Regardless of the difficulty involved, it is good practice to test the temperature of every batch of mineral aggregate in plants of this type before it is mixed with the asphalt cement; otherwise regular work cannot be expected. Even when the greatest care pos-

sible is exercised, there will be considerable variation in the mesh composition and temperature of the mineral aggregate as delivered to the mixer. The permissible variations are usually set forth in the specifications and should be closely observed. Mixtures which vary very greatly in mesh composition will require different amounts of bitumen in order to make the best possible type of mixture. Within ordinary limits, no correction will have to be made for this, but, generally speaking, a mixture containing a large proportion of fine particles will require more bitumen to cover these particles than a mixture containing a smaller proportion of them. This is due to the fact that the finer the mixture the greater the surface area to be covered with bitumen. This can, perhaps, be most clearly shown by taking the case of a 1-in. cube which it is proposed to coat with bitumen. In its original state there will be six sides having an area of one square inch each to cover. If this cube be cut into two cubes, there will be the original six sides plus two additional sides to be covered, and every time that the cube is cut there will be an increase in the surface area to be covered with bitumen. In order to secure a satisfactory output from the plant, it is absolutely essential that the greatest possible care should be taken in the mixing and heating of the mineral aggregate. In order to insure the proper mixing of the mineral aggregate, it will be necessary from time to time to take samples of the mixed aggregate and sift them for mesh composition. Owing to the extreme difficulty of securing an average sample of hot, dry mineral aggregate, great care must be exercised in selecting the samples. The arrangement of the plant and the kind of mineral aggregate used will determine where and how often these samples should be tested.

The speaker is inclined to advise the obtaining of samples for test from the overflow of the feeding device used in conveying the cold mineral aggregate to the heating drums. This is usually done by a chain and drum elevator. Where these buckets dump into the chute at the entrance of the drying drums, there is almost always a small overflow which gradually piles up underneath this chute. Assuming this to be the case, the pile can be cleaned off at a given time and the material which accumulates during, say, half an hour's run can then be sampled, dried and sifted. It is much easier to sample the damp material than it is the dry, and this not only obviates some of the difficulties attendant upon sampling dry material but gives the inspector an average of the material fed into the drums during the half hour while the pile was accumulating. In this way much better average results are obtained and the inspector is not liable to be misled by temporary and unimportant lapses in the feeding of the material. In other cases, samples of the hot material are obtained from the delivery end of the drying drums. In such cases a number of samples should be collected and mixed together and the resultant mixture sifted.

Preparation and Heating of the Asphalt Cement or Bituminous Binder.—For the preparation of the asphalt cement or bituminous binder, the contractor may purchase a hard bituminous material and add sufficient flux to it to bring it to the proper consistency, or he may purchase an asphalt cement of the proper consistency for use without the addition of any flux. In the first instance the melting kettles will have to be charged with the proper proportions of flux and hard asphalt to produce the desired asphalt cement. In large plants this is generally done at the close of the day's run. The materials are then kept under a gentle heat during the night and brought up to the desired temperature in the morning. The contents of the kettles are then thoroughly agitated in order to insure complete mixing of the different ingredients and a sample from them is taken and tested for penetration before the contents of this kettle are permitted to be used. If it is too hard, more flux will have to be added to it. If it is too soft, more hard asphalt will have to be added to it. After the additions are thoroughly melted, the contents of the kettle must be again agitated and tested before using. Certain asphalts are more difficult to flux than are others and require a longer period of heating. Overheating of the kettles will result in undue hardening of the asphalt cement. If the flux or hard asphalt contains any considerable proportion of water, this will foam very badly in the kettles and frequently cause them to run over. No asphalt cement or bituminous binder should be used until the water has been thoroughly removed from it. Where the asphalt cement or bituminous binder contains a considerable proportion of mineral matter or impurities, the contents of the melting kettles must be kept thoroughly agitated during the time that they are being drawn upon for use. Suitable mechanical agitation is, perhaps, the most advisable, as in this way the bituminous material is hardened less than if a steam or air blast is used.

Violent agitation with steam or air will very rapidly lower the penetration of the contents of the kettles. In the case of asphalt cements containing a considerable proportion of mineral matter, unless the contents of the kettles are thoroughly agitated, the material drawn from them will vary in purity or bitumen contents with the result that the portion first taken from the kettle will usually run much higher in bitumen than the portions last taken from it. Assuming that the proportions of the mixture have been set to give the desired quantity of bitumen, based on the average bitumen contents of a thoroughly mixed kettle, the mixture turned out with the asphalt cement first drawn from the melting kettle will be too rich in bitumen and that turned out with the asphalt cement last drawn from the kettle will be too low in bitumen. It is impossible to estimate by observation the changes in weights of asphalt cements necessary to overcome this and the only proper way, therefore, is to so agitate the contents of the melting kettles that the supply of the bituminous material drawn from them will be uniform in bitumen contents. If for any reason the asphalt cement for a certain day's run is not entirely used up, it should always be tested for penetration before permitting its use on a subsequent day's run. There is, of course, no objection to filling up the balance of the kettle with new material and mixing it thoroughly with the portion left from the previous day's run. It should then be considered as a new batch of asphalt cement and tested accordingly. Where hard asphalt and flux are to be melted together, the contractor should never be permitted to draw any material from the melting kettles until their contents have been completely melted and thoroughly mixed. Even where the asphalt cement is purchased ready for use, it is not good practice to draw from a kettle containing lumps of unmelted bituminous material. Sufficient melting kettle capacity should be insisted upon to avoid the necessity of doing this.

With the exception of the fluxing, the foregoing remarks apply equally to bituminous binders, purchased by the contractor, of the proper consistency for use.

Mixing of the Heated Mineral Aggregate With the Hot Asphalt Cement or Bituminous Binder.—It is unquestionably the best practice to weigh out the various ingredients entering into the composition of the finished mixture. Where the different ingredients are measured by volume, much greater variations will occur than when

they are measured by weight. If measured by volume, the contents of the various measuring devices must be carefully checked up before the commencement of the work and the gauges set at the proper point. It is advisable to check up the setting of these gauges from time to time to see that they have not been displaced, either intentionally or otherwise. In determining the volume occupied by the desired weights of the different ingredients, it is necessary to measure them at the temperatures and under the conditions used in actual work. In other words, heated dry sand or stone must be filled into the measuring box and the weight of the box when filled to the proper mark determined. This is also true of the bucket or measuring device used for asphalt cement or bituminous binder. If the asphalt cement should contain any water, this will produce foaming and it will be impossible to measure it accurately. If the foaming is at all excessive, it will be impossible to get the required amount of asphalt cement in the ordinary sized measuring bucket. This, by itself, constitutes a sufficient reason for not permitting the use of any asphalt cement which contains water. Where the materials are measured by weight, the tare of the empty measuring devices must be carefully obtained and this tare added to the weight of materials which it is desired to use. In determining the tare of the asphalt cement bucket, it must be borne in mind that after an hour's run there is a considerable accumulation, amounting to several pounds, of asphalt cement on this bucket which will increase its tare above that obtained by weighing the bucket in a perfectly clean state. After once determining the tares and setting the weights or gauges at the proper point, their position on the scale beams or elsewhere should be checked up from time to time to see that they have not been displaced. Occasionally the accumulation of surplus material on the scale platforms of the measuring device for the mineral aggregate will change the tare somewhat. Any such accumulation should be removed from time to time as often as necessary. Unforeseen happenings will occasionally influence the tare of the measuring devices. In the speaker's experience, he once found that the mixture being turned out was entirely too sloppy, although he had but a short time before carefully checked up the tare and gross weights of the various ingredients entering into it. Upon investigation, he found that the spout carrying the materials from the hot sand bin had been shifted by the vibration of the machinery so that it rested part of its weight upon the sand box, thus increasing its tare by approximately 200 pounds. Each batch of mixture turned out under these conditions, therefore, contained 200 pounds too little mineral aggregate, which, of course, accounted for its sloppiness.

The method of mixing varies in different plants. In the larger sized paving plants almost invariably the pug mill type of mixer is used, and this the speaker considers much the best type. The blades in this type of mixer should be examined to see that they are properly set and not unduly worn, thus producing an imperfect mixture at the bottom and sides of the mixer. Ordinarily they should revolve at a speed of from 60 to 80 revolutions per minute. In mixtures of the sheet asphalt type, one full minute should be allowed for mixing each batch of material. Where the mixture is a comparatively open one consisting largely or entirely of stone, this mixing time may be reduced somewhat. Whatever the type of mixer employed, the proper time for obtaining a thorough mixture should be determined and rigidly adhered to. The temperature of the mineral aggregate delivered to the mixer should be tested occasionally, as often as may be necessary. This, of course, will depend upon the type of plant used and is a check upon the drum fireman and the feeding operations of the mineral aggregate. The temperature of the asphalt cement in the melting kettles should also be tested as often as may be necessary in order to be certain that it is uniformly maintained at the proper point. Where the type of mixture permits it, frequent pat tests should be taken of the material delivered to the wagons. This test is made by placing a small quantity of the hot mixture upon a sheet of unglazed manila paper, folding over the paper and pressing down upon it with a wooden paddle. After it is thoroughly compressed, the paper should be struck a sharp blow with the wooden paddle and then opened for observation. An examination of the surface of the compressed mixture will clearly show to the trained inspector any marked variations in the mesh composition of the mineral aggregate. The depth of stain upon the paper will measure the amount of bitumen which it contains. The richer the mixture in the bitumen the heavier will be the stain. This stain is also influenced by the temperature of the mixture when the pat test is taken. For this reason it is necessary in comparing pats to know exactly the temperature. In obtaining the mixture for the pat test from the wagon, an ordinary mason's trowel will be found convenient. No time should be lost after obtaining the sample in putting it upon the manila paper and making the test; otherwise it will drop very considerably in temperature. The temperature of the material tested can be conveniently determined by inserting a thermometer at the place where the sample was taken from. Convenient and suitable arrangements for making this test should be insisted upon at the plant. This is a most important and valuable guide in the hands of a competent inspector and great attention should be paid to it. In the hands of a trained man, a variation of one-quarter of one per cent. of bitumen can be detected by means of the pat test. This pat test is, of course, not applicable to mixtures consisting chiefly of large particles of stone. The inspector should make careful notes of the various conditions surrounding the plant. He should take and record at least three times daily the temperatures of the asphalt cement and the mineral aggregate as delivered to the mixer. He should also record his siftings of the mineral aggregate together with the proportions used in making the mixture and of the asphalt cement.

All deliveries of material at the plant should also be noted and a record kept of any tests made on them. These records should be kept on properly designed forms and should state the name of the street on which the mixture is being laid, the kind of mixture and the kind and proportion of the various ingredients entering into it. He should also keep a record of the number of batches turned out from the plant, as this is a valuable aid in checking up the thickness of the pavement laid on the street. At the commencement of the day's run it is customary to send out mixture which is a little hotter than that sent out during the average operations of the plant. This is done in order to enable the workmen on the street to make a close and intimate joint with the pavement laid during the previous day's run. While safe temperature limits should not be exceeded at any time, the maximum limits should be approached in sending out the first few loads in the morning.

Street Inspection.—Prior to the delivery of any bituminous materials upon the street, the foundation must be completed in accordance with the requirements of the specifications. The finished foundation must then be

swept clean of all dirt, etc. Knowing the type of mixture to be laid and the number of pounds used in each batch and the number of batches per wagonload, it is usually possible to determine in advance how many square yards should be covered by each wagonload. The best street foremen, before laying any bituminous material, measure the width of the street and calculate the number of lineal feet which should be covered or "pulled" by each load. A tape is then laid along the curb and a chalk mark made at the point where the raked material from each load should end. Where the foundation is reasonably smooth and in accordance with the contour of the finished pavement, this method is one of the best checks for determining the thickness of pavement laid. Ordinary sheet asphalt pavement 2 ins. thick will weigh 200 pounds to the square yard. Pavements containing a large proportion of good sized stone will vary somewhat from this weight, but the exact weight per square yard can easily be determined during the first day's run.

As soon as the material reaches the street, its temperature should be noted. The hot material should be dumped outside of the spot where it is to be laid in order that all of it will have to be conveyed to its final resting place by means of shovels. This results in a preliminary spreading of material of approximately the same density. Where the load is dumped on the spot on which it is to be spread it will inevitably be tramped upon and certain portions of the heated mixture will receive more compression than others, which will eventually result in an uneven surface to the finished pavement. In certain classes of bituminous mixtures, notably those containing large particles of stone, where the haul is long, the coarser particles may settle to the bottom of the load. If this takes place to any great extent, the load when dumped should be re-mixed by turning over with hot shovels. In shovelling the hot mixtures into place the shovellers should not dig into the top of the pile but should shovel from the bottom of it, cleaning up the loose material as they go. If this is not done, the lower layer of the pile, in cold weather, will have become chilled by its contact with the cold foundation and it will be difficult to remove it completely and uneven distribution and compression will result. The mixture, after having been deposited roughly in place by means of shovels, is spread by means of hot rakes. During this operation the rakers should not stand in the hot mixture any more than is necessary. Care should be taken to maintain a uniform and even grade so that there will be no depressions in the finished pavement which will hold water. Some mixtures compress very much more than others, so that it is impossible to establish any definite rule for the depth to which the hot mixture shall be raked.

As soon as possible after raking, the mixture should be rolled. Some mixtures are more tender than others and must be allowed to cool off somewhat before putting the hot roller on them. The hotter the mixture, the greater will be the compression and it is, therefore, desirable to roll it as soon as possible. In very cold weather, especially when a strong wind is blowing, the surface of the mixture will chill quite rapidly. With a tender mixture it is often advisable to use a light hand roller over it as soon as it is raked in order to close up the surface and then follow this with a heavy steam roller as soon as the mixture will bear it. Undue delay in rolling the mixture will result in a more or less honeycombed surface. Depending upon the contour of the street and its width, the rolling should be first done parallel with the curb. This should be followed by diagonal or cross rolling and the final finish of the work by rolling parallel to the curb again. The exact method of handling the roller can usually be left in the hands of the roller engineer if he is an experienced man, as he should know how to smooth up the finish of the pavement better than will the average inspector. At the finish of the day's work it is necessary to leave the pavement in such condition that a proper joint may be made with it when the next day's operations are commenced. There are a number of methods of doing this. Perhaps the best is the rope joint in which a length of rope is laid across the extreme edge of the pavement and rolled into it while hot. When this is taken up very little cutting back will have to be done and the edge will be left in such shape that a satisfactory joint can be made. The practice of painting these joints with hot asphalt cement before laying fresh pavement adjacent to them is to be avoided whenever possible, as the tendency is to put too much asphalt cement on the joint. This asphalt cement is absorbed by the hot mixture and softens it at that point and traffic is liable to displace it. For the same reason the painting of edges of curbs, manholes, etc., should be done with extreme care. A very convenient instrument for determining the depth of the finished pavement is a putty knife with a blade 2 in. wide which has been marked across the face of the blade at a point corresponding to the required depth of the pavement. This can easily be inserted in the warm mixture after it has been rolled and the broad point will bridge over any small depressions in the foundation and avoid the recording of a greater depth to the pavement than really exists.

The use of hot smoothers should be avoided whenever possible. With the proper mixture and one which has been rolled while hot, the surface should be entirely closed up. Under unfavorable weather conditions, in order to close up the surface, it may be necessary in certain places to use hot smoothers. Care should be taken to see that these are not too hot; otherwise they will burn the pavement and scaling will eventually result. The inspector on the street should, whenever possible, keep an accurate account of the number of loads delivered. Knowing the number of pounds of mixture per load and the weight per square yard, he can then check up the yardage which should have been laid with the material delivered on the street if it were raked to the proper thickness.

Inspection of Finished Work.—If the inspection at the plant and street during the construction of the pavement has been adequate, the final inspection of the work will be chiefly confined to an examination of the contour and surface of the street. During this examination careful note should be made of whether or not the mixture has been thoroughly compressed and is closed up on the surface. Where there has been no inspection during the manufacture and laying of the pavement, or where this inspection has been inadequate, defects will frequently develop in the pavement. Under these circumstances, it becomes necessary to examine the finished work in order to determine the reason for the defects or failures. In an inspection of this sort, careful note should be made of the condition of the surface and its contour. Frequently marked depressions occur where the pavement has been laid over a trench dug just prior to its construction, and in which the back-filling was not properly done. A thorough examination of the street will usually involve the cutting out of numbers of samples of the bituminous surface. These should be carefully marked as to location and a sufficient number of them taken to fairly represent the surface examined. They should be sent to a central

laboratory for examination as to the per cent. of bitumen contained in them, the mesh composition and character of the mineral aggregate and the physical and chemical characteristics of the asphaltic cement or bituminous binder used in the pavement. Wherever these samples are cut out, careful note should be made of the depth of the pavement at this point. In many instances it will also be necessary to cut through the foundation to determine its character and thickness. Laboratory examinations of concrete foundations are usually not very valuable in determining the amount of cement which has been used in them, but a combination of physical and chemical tests of the foundation will often establish satisfactorily whether or not they have been defective. The method of examination used will, of course, have to be varied depending upon circumstances and the character of the defects which have been developed. The reasons for these defects have been fully covered by a previous lecture delivered by the speaker to which he would refer you for more detailed information on this point.

PANAMA-PACIFIC EXPOSITION CONSTRUCTION.

Rapid progress is being made on the construction work in connection with the numerous large wooden buildings for the Panama-Pacific International Exposition at San Francisco. Among the principal buildings already erected are the Palace of Machinery, covering three acres, the Fire House, the Education Building, the passenger station, and warehouses, ferry slips and oil houses. The framework has been started for the buildings for Mines and Metallurgy, Various Industries, Manufactures, Liberal Arts, Food Products and Agriculture.

Thirty-five states and territories and certain of the foreign governments have announced their intentions to secure space; 177 congresses and conventions have been arranged to meet in San Francisco during the fair, and an attendance of from 10,000,000 to 18,000,000 is anticipated for the exposition. It is said that neither Germany nor England will take exhibit space.

The cost of the exposition is estimated at $80,000,000, of which the state of California and the city of San Francisco will each pay $5,000,000, San Francisco subscribes $7,500,000 and individual exhibitors $25,000,000.

The Toronto Suburban Railway Company has just closed a contract with the Canadian General Electric Company, Limited, for substation apparatus and car equipments, for the new line which will run west from Toronto through Georgetown, Guelph and Berlin. A very interesting feature is that this will be the first interurban line in Canada to operate at 1,500-volts D.C. The catenary type of overhead construction will be used, and there will be three substations, viz., at Islington, Georgetown, and Guelph. 1,500-volt rotary converters, each of 500-k.w. capacity, will be used, power being transmitted to the substations at 25,000 volts. Provision will be made for the supply of power from a separate bank of transformers in each substation for distribution along the line for miscellaneous power and lighting purposes. The cars will be equipped with four 85-h.p. motors of the latest type, and fully ventilated. The control will be of the multiple-unit type. The cars will operate on 600-volt line at approximately half normal speed; and changing from 1,500-volt to 600-volt trolley, or vice-versa, will involve no loss of time in adjustment of control apparatus. The line with 1,500 volt operation will be about 61 miles long.

EFFICIENT WATER PURIFICATION IN SMALL PLANTS.

SEVERAL interesting papers and reports have recently appeared dealing with the operation of sewage disposal plants and emphasizing the necessity for more careful supervision of this kind of municipal work. It is well known to all who have investigated the matter that small sewage disposal plants receive as a rule little or no attention, and that their effluents could be greatly improved under proper operation.

As an instance of the application of this reasoning to water purification plants, one of our smaller cities operates a filter plant at an average efficiency of 79 per cent., and which was at one period as low as 50 per cent., whereas, according to a report just received from a consulting engineer, who has made a thorough examination of the system, an efficiency of 95 per cent. could be maintained if the plant was placed under proper scientific supervision.

Mr. H. P. Letton read a valuable paper on the subject, at a meeting of the New England Water Works Association recently. Mr. Letton was for some years in the employ of the New Jersey State Board of Health, engaged mainly in the supervision of the public water supplies of the state. He is now sanitary engineer to the United States Public Health Service. In his former position about 30 water purification plants were under constant inspection.

According to his paper, the main difference between the operation of sewage disposal plants and small water purification plants is that the former are usually built, not because there is a concerted demand for them, but for the eradication of a local nuisance, or by order of some higher authority. Because of this fact, and because the terms "sewage" and "sewage disposal" are distasteful to the average layman, the plant is generally put in an out-of-the-way place, and either forgotten entirely or placed in the charge of an underpaid, superannuated caretaker, who knows nothing of the principles upon which the design of the plant is based; while a water purification plant is generally installed as a result of a popular demand, and the consumer is directly interested in its operation in so far as furnishing a clear, colorless, and palatable water is concerned. These are the qualities that to the majority of people determine the purity of the water, and as long as they are maintained there is little or no question as to the efficiency of the plant in other ways. As a matter of fact, however, there are many plants which will usually meet the above conditions, but which are inefficient, both from an economic and a sanitary standpoint.

It is only on rare occasions that a filtration plant has been constructed at the time of the installation of the water works system. In most cases, when the purification plant is added to an existing system, the operation of it is intrusted to the engineer of the old plant. This man may be, and in many cases is, a stationary engineer who thoroughly understands the operation of boilers, engines, and pumps, but who has absolutely no idea of the principles which underlie the process of water purification.

There is also another point which in many cases affects the results obtained. When it is decided that some form of purification is advisable in connection with a small water plant, it is very rare, indeed, that a consulting engineer is called in for advice. Instead, the matter is taken up with one or more companies engaged in the business of installing purification apparatus. While

these companies are usually competent to give reliable advice, their main business is the selling of equipment. Because of this fact and because the usual small water company or municipality is weak financially, the filter plant is designed to fit the available money, and the company offering the equipment for the least sum is generally given the contract, regardless of the quality of the material to be furnished. As a result of this practice, plants that are poorly designed, lacking in the necessary equipment for efficiency, or even wholly ill-adapted to the situation, are commonly met with. A few cases of this kind which have come under the observation of the writer will be noted. Probably the worst example was at a plant supplying about a million gallons per day. The supply was originally obtained from artesian wells, but on account of the high iron content of the water, a new supply was obtained from an artificial lake. This water was highly colored by its passage through cedar swamps. From the lake the water flowed by gravity to the coagulation basin. This was a rectangular wooden tank of such size that normally less than twenty minutes were allowed for coagulation and sedimentation. During periods of high consumption the time was considerably decreased. The basin was set at such an elevation that at times of low water in the lake it was impossible to obtain the normal supply except by by-passing some raw water. From the coagulation basin the water flowed by gravity to 4 rapid sand filters of the gravity, circular wooden tank type, without loss of head-gauges or rate-controllers. The agitating rakes were intended to be driven by a water motor, but the necessary power was lacking. The beds were, therefore, not agitated during washing. From the filters the water passed to a suction well which had been used in connection with the former well supply, and which provided less than 30 minutes' storage. Two solution tanks had been provided and connected with a small displacement pump driven from the line shaft to which the main water pumps were attached. The small solution pump was intended to force a solution of sulphate of alumina into the raw water just before it entered the coagulation basin. At the time of the writer's first visit to this plant the chemical pump was out of order and no chemical was being added. It was afterward learned that this was its chronic condition. Tests of the raw water showed it to be slightly acid owing probably to humic acid from the cedar swamps. Consequently the addition of sulphate of alumina would be an absolute loss as far as results are concerned. Analyses of the raw and filtered water showed no material difference, and the filtered water had at times a color as high as two hundred.

While the foregoing may seem to be an extreme case, conditions almost as bad were found in several instances. Two other plants were discovered treating acid water with sulphate of alumina only, rate-controllers and loss of head-gauges were almost unknown, and the methods of regulating the amount of chemical applied were very crude. Few calibrated orifice boxes were found in use. Two gravity, rapid sand plants, treating waters high in organic matter and often turbid, had no coagulation basins, so that they required too frequent washing with corresponding reductions in bacterial efficiency as well as increased costs of operation. Another large plant, using the pressure type of filter, was treating a turbid water with very little time for coagulation. The effluent was frequently turbid, and at times contained aluminum hydrate.

One plant of the slow sand type had less than a foot of filtering sand, and had a clear-water well holding about a half hour's supply. As a result of this combination, the rate of filtration fluctuated exactly as the demand, and purification was practically nil.

At one rapid sand plant the clear-water basin was so small that it was necessary to wash with raw water. Another plant had no arrangement for filtering to waste, so that whenever it was necessary to get at the strainer system the dirty water in the bed was drained into the clear-water well.

On the matter of operation, conditions were found to be as bad, if not worse. As has been said, the man in charge of a small water purification plant has usually little or no idea of the nature of the process. He operates the plant by "rule of thumb" methods in an endeavor to produce a good-looking water. Although efficient results depend so largely upon the use of the correct quantity of coagulant, the greatest ignorance was shown of this matter. At several plants the engineer stated that he put in a certain number of buckets of alum per day. He did not know how many pounds were used, and made no attempt to add it in the same proportion at all times. A few engineers said that they increased the dose "some" when the water was turbid, but did not know how much. In only a few plants was any attempt made to regulate the dosage by the aid of alkalinity and turbidity tests. As a matter of fact, few of the men in charge could be depended upon to make the necessary alkalinity tests. At only two plants, treating less than twenty million gallons per day, were laboratories maintained, and at these plants the tests, both chemical and bacteriological, were made under the direction of non-resident chemists. The engineers who made the tests were unable to interpret them or apply them in the operation of the plants. At one modern municipal plant, absolutely no records were kept. The chief engineer could neither read nor write, and could see no use in records of any kind, not excepting pumpage records. The president of the board of water commissioners in charge of the plant stated that the only reason he could see for filtering water was to remove turbidity, notwithstanding the fact that the sewage of over a hundred thousand people was discharged in the river, from which the supply was taken, about seventeen miles above the intake.

At one plant visited, it was found that through the laziness of the engineer the filters were not being washed enough, the deficiency of water due to clogging being made up by by-passing raw water. At another plant, the beds were washed too often, resulting in a low bacterial efficiency and a high cost of operation. Oven ten per cent. of all water filtered was being used for wash water.

It is not believed that such cases are confined to New Jersey. Reports of investigations in Ohio, Pennsylvania, New York, and Illinois show very similar conditions. Much as they are to be deplored, the fact remains that they do exist, and that a discussion of possible remedies is in order.

The most feasible remedy for poor design is a statute requiring the submission of plans for proposed plants or changes in existing plants to the state board of health, or some other state authority, for approval before construction can legally be carried out. Such a regulation is in effect in a number of states at the present time. Coupled with the appointment of a properly qualified engineer to pass upon all plans, it will satisfactorily care for new works. State supervision for existing plants will, if carried out, do much to remedy the more serious imperfections of construction and operation. This supervision cannot, however, be thorough enough to furnish definite information for the efficient operation of the

plant, both from an economic and a sanitary standpoint. At best, the plant can be visited only about once a month, and this visit is merely to see that a safe and potable water is being produced. From the viewpoint of the state this result is sufficient, but from that of the consumer and taxpayer there are other matters of great importance. He wishes to know, first, that the water is healthful, and then, that it is not possible to obtain the same or better results at a less cost by some change in the method of construction or operation of the plant. This latter is out of the field of the state inspector, for it generally requires much experimenting and testing to obtain the point of maximum efficiency.

The plan of having the engineer at the plant make daily tests under the general direction of a consultant at a distance is a step in advance, but it is far from perfect. The engineer's results are open to question, since he is often hurried and makes the tests without knowing the reason for the various steps. Also, since he has but infrequent consultations with the consulting engineer or chemist and is unable in most cases to explain any seeming discrepancy in his results, they do not prove to be of as much value as might be expected.

The writer has had in mind for some time a plan for remedying this situation, and it has recently again been brought to his attention by a similar plan which Prof. Earle B. Phelps has put into operation in connection with local health administration in several small Massachusetts towns. The plan is this: For several water companies or municipalities located not too far apart to combine forces, fit up a laboratory at some central point, and employ a competent bacteriologist and chemist to give his entire time to the scientific supervision of their water plants. By so doing, each plant would have the benefit of expert advice at a small cost. It would be possible for the chemist to visit each plant one or more days each week, and by so doing to become familiar with its operation. He could instruct the engineer in charge of the plant how to make the necessary daily chemical tests, such as alkalinity, turbidity, etc., and since he visited the plant so often, these results could be checked up and would be reliable. In case of emergency he would be able to look after the sanitary quality of the water and thus protect the consumer. He would be able to carry on experiments upon the proper amount of coagulants to be used, and time of coagulation. There is a chance for much study in the manner of washing the filters to bring about efficiency and economy. This is a point not considered much in small plants, but which has a considerable bearing on the cost of operation. It requires many visits to a plant to become familiar with its operation and to suggest changes which will increase its bacterial efficiency without increasing the cost. It is believed that the scheme outlined would in many cases save money for the water company or municipality, besides giving them and their consumers confidence that the quality of the water was being safeguarded.

A group of English engineers were recently accorded the contract for bridging the Ganges of northern India, which issues from an ice cave at the foot of the Himalayan range of mountains. This bridge, which is over a mile in length, is to carry the Eastern Bengal State railway over the Ganges from Damukelia to Sara Ghat. Spanning the river, the bridge will be crried on steel trestles, which in turn will be supported on massive steel grilles in granite piers. The contract consists of fifteen main spans, each 359 feet long and 52 feet high, and weighing 1,300 tons, and will require an expenditure of about $1,250,000.

ESTABLISHING A RAILWAY ROUTE

By J. A. Macdonald, Ottawa, Ont.

RUNNING **the Preliminary Line.**—Having, by reconnaissance, found approximately the location for the proposed road, the next procedure is to run a trial line with the transit, selecting what appears to be the best on the ground, staking out the centre line, and sketching in the topography on both sides.

In following the bed of a stream, we obtain, generally, a line similar to *A N C* upon the section (Fig. 1). The lowest line of the valley, though quite moderately inclined at first, may rise more and more rapidly towards the source of the stream, as shown by the closer approach of the contour lines on the plan. That the line may ascend at a uniform rate from *A* to the summit, the horizontal distance between the contour lines may be equal at all parts of the ascent. This condition is effected by causing the surveyed line to cut the contours at right angles during the first part of the ascent, and obliquely as the summit is approached, or as the contours become closer together. In this manner we obtain the profile *A M*, *M A*. The contour line is level; the line cutting the contour at right angles is the steepest line that the ground admits of; and as we vary between these limits, we vary the inclination.

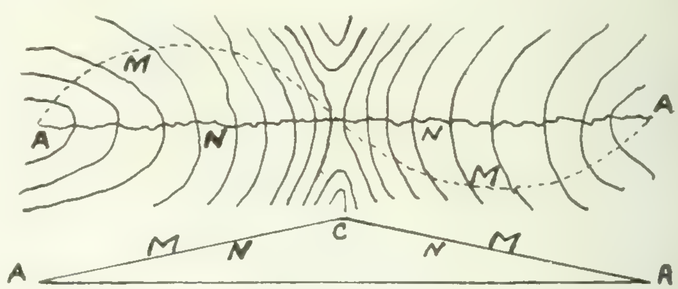

Fig. 1.

The effect upon the profile of cutting the contour lines in different directions is shown by Figs. 2 and 3. If we connect the points *A* and *B* upon the plan (Fig. 2) by the straight line *A B* we obtain the profile shown in Fig. 3 by the line *A L N M B*. If we follow the contour line around from *A* to *B*, we should have the horizontal line *A B* on the profile, and if we select a route upon the plan midway between the straight line and the contour line, as *A E F H B*, we shall have, as the corresponding profile, *A E F H B*, (Fig. 3). In connecting the points *C* and *D*, which are at different elevations, by the straight line, *C D*, we get the profile *C I P K D*. If we wish to descend upon the natural surface at a uniform and given rate—from *C* to *D*, knowing the rate of incline and the vertical distance between the contour lines, we get at once the corresponding horizontal distance from one contour line to the next, which, applied to Fig. 2, would give the required descent, as shown on the profile by the straight line from *C* to *D*. The line *A E F H B*, on the plan, is, of course, longer than the straight line *A B*; and the contour line is longer still. Such increased length is not represented upon the profile, as the object has been simply to show the general relation between the plan and profile, and the use of correctly drawn contour lines in adjusting any route to the ground.

General Establishment of Grades.—In the application of grades or incline to the establishment of a rail-

way route, we should bear in mind that between two points, which are at the same absolute elevation, there should be as little rise and fall as possible, and that between points at different elevations we should endeavor to have no rise while descending, and consequently no fall upon the ascent. These conditions can seldom be exactly complied with in practice, but we may approach them closely. In many cases we have to choose between two systems of grades—the one involving a long but gradual and uniform rise, the other a short but steep ascent, with the remainder of the line level, or nearly so. The total resistance upon the two systems, involving the same amount of ascent, will be the same; but a great difference may be made in the method employed in overcoming that resistance. If we have a grade 10 miles long, rising at the rate of 20 ft. per mile, we adapt our

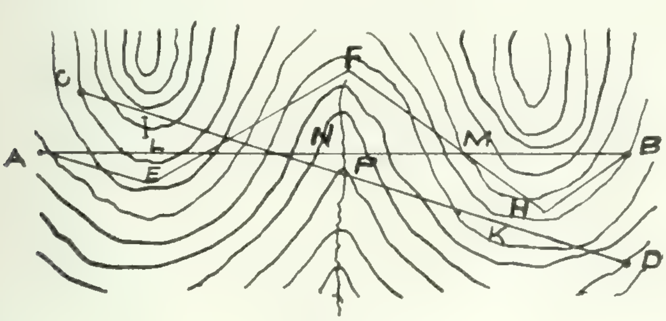

Fig. 2.

machinery to hauling its ordinary load up that incline, and we require from it a constant expenditure of power while ascending, and on the descent it is profitably aided all the way by gravity. If, however, the first 8 miles are level, and the remaining 2 miles ascend at the rate of 100 ft. per mile, an engine to work the incline would be too heavy for the level portion, and in the descent we should have more aid from gravity upon the incline than we required with none at all upon the level.

The effect of the arrangement in detail of the grades upon the amount of work to be done in reducing the natural surface of the ground to the finished roadbed, is shown in Fig. 4. The level grade from *A* to *B* involves a large amount of earth cutting at *D* and *E*, and a large amount of embankment at *C*. By raising the grade lines *D′* and *E′*, in the cuttings, and depressing the level em-

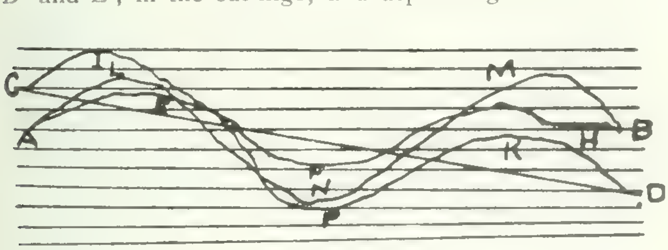

Fig. 3.

bankment from *C* to *C′*, we at once reduce both amounts of excavation and embankment, and by raising the roadbed more, to *D″* and *E″* in the cuttings, and depressing it to *C″* upon the embankment, we reduce still more the quantity of work to be done, but at the same time we render the road more difficult of operation.

There are many points that govern the rate of grade of a new railway. Probably first of all is the capital at disposal of the promoters of the road; for plenty of money will make possible an almost level line. But often the tremendous cost of such a level road would never pay dividends, notwithstanding this advantage. The country through which a road is to pass largely governs the most economical grade. If a comparatively level country, then there is no necessity at all for steep grades on the grounds of economy. If, on the other hand, the country is rough, the grade must be made to conform first with the amount of capital available, and, secondly with operating expenses.

The question of interest at which the money can be borrowed also enters very largely into that of grades.

It is doubtful if it were wise economy on the part of the C.P.R., when building its road across the continent, to make the grade limit so steep. Money was at a much lower rate at that time than now, and the vast sums of high-priced money that have been used in the past few years to ease the gradients might better have been used on the original work. This goes to show that faith in a railway enterprise also governs the gradient. When the C.P.R. line was being constructed a great many people had little faith in the successful outcome of the enterprise, while the problem of crossing the Rockies was

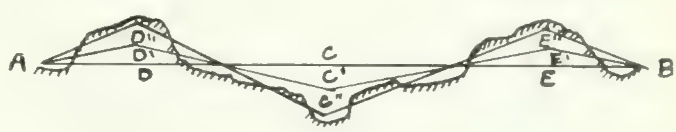

Fig. 4.

considered by many to be almost an impossibility. Money-lenders, not being greater endowed with prophetic powers than any other class of people, held the general view, and it was only with the greatest difficulty that the money could be found to construct the road on the original plan of steep grades. Faith in any enterprise is, therefore, of great importance, and particularly so in the building of a railway.

We think the reconnaissance line of a railway of considerable length is not generally given due importance in this country. Certainly, no decision as to suitable grades and curves should be arrived at before a full report of the exploration or reconnaissance survey has been received. We also think that these exploration surveys are not usually complete enough. Besides determining the most economical ruling grade, the possibilities of the country as to production, available freight and passenger service, contiguity to water transportation, are of almost equal importance with the gradient. These latter points, however, are usually neglected in the exploration line, the whole interest being centered in the grades.

A statistical report on the operation of electric railways throughout Canada in 1913 has recently been published at Ottawa. There are 56 electric railways in Canada, and during the year ending June 30th, they carried 598,662,801 passengers, exclusive of transfers, and 1,957,930 tons of freight. There was an increase in the number of passengers over 1912 of 108,998,119. The mileage of the railways increased during the year by 142 miles. The gross earnings of the electric roads in [illegible] was $25,216,111, an [illegible] over 1912 of $4,716,861. In five years the earnings of the electric railways have more than doubled. During 1913 the earnings from passengers was $19,794,400; from mail and express, $72,516 and from freight, $1,211,871. The operating expenses amounted to $17,765,372, leaving $10,450,738 as gross corporate income in addition to $1,318,909 of miscellaneous income, making a total income of $11,[illegible]. A surplus of $2,058,742 was carried after taxes, debt, interest and dividends were paid; and an addition of $55[illegible] was made to the reserve.

NELSON AND CHURCHILL RIVER BASINS.

A REPORT (Memoir No. 30) has recently been issued by the Geological Survey Branch, Department of the Interior, on the basins of the Nelson and Churchill Rivers. The information was compiled by Mr. Wm. McInnis and is largely the result of his own personal investigations. References are made also to the geological work of Bell, Tyrrell, Low, Cochrane, McConnell and Dowling, all of the Geological Survey.

Topography.—The region, broadly considered, forms part of the extensive Pre-Cambrian peneplain of northern Canada, encroached upon, to the northeast, south, and west, by more recent, flat lying, sedimentary rocks. The peneplain surface has an elevation, in the northwestern part of the area, of from 1,300 to 1,500 feet above the sea, but gradually diminishes in height eastward to the broad declivity through which Nelson and Hayes rivers,

Fall on the Rapid River, Near the Churchill.

and, in part, Churchill River, flow to the sea. In the neighborhood of Sipiwesk Lake, which lies about in the middle of the depressed area, the elevation of the surface above sea-level is about 600 feet. There are no high elevations, and the general level of the interstream areas is not more than 100 to 200 feet above the level of the streams.

The plateau has a gently rolling surface characterized by rounded outlines which have resulted from long continued and profound erosion. It is intersected by rivers and streams innumerable and is dotted with lakes of all sizes. The river valleys are moderately depressed, and are made up generally of chains of rock-bound basins which form series of lake-like expansions along the rivers, the water spilling over the lowest part of the rims and flowing from basin to basin with swift current or over a succession of rapids and falls.

The surface is wooded throughout, though, except in the valleys of the larger streams, the forest growth is of small size. North of latitude 59° or thereabouts, the forest is mainly black spruce and tamarack of stunted growth, a growth which characterizes also the muskeg portions of the southern area.

To the northeast, where the horizontal limestones of the Hudson Bay basin overlie the older rocks, the surface is of the nature of a gently sloping, flat plain. The level character is due, in part, to the horizontal attitude of the rocks and, in part, to a covering mantle of boulder clay

Sea-river Fall, Nelson River.

of somewhat uniform thickness. In this, and to some extent in the underlying, solid rock, the rivers have trenched narrow channels, which constitute the only breaks in the surface.

The overlap of the Cretaceous sediments to the south is marked for a hundred miles west of Lake Winnipegosis by the bold escarpments of the Porcupine and Paskwia hills, and farther west by the equally high but gently sloping outlines of the Wapawekka hills.

The country about Montreal Lake and east of it is characterized by heavy accumulations of drift. which form somewhat prominent hills that reach heights of over 2,000 feet above the sea.

Drainage.—The whole of the area under consideration, except a small tract in the northwest corner, is drained by rivers flowing to Hudson Bay; of these, the Nelson and Churchill are the largest, the first named taking rank among the half-dozen largest rivers of the continent.

Sturgeon-wier River, Saskatchewan.

The Nelson, which empties from Lake Winnipeg into Hudson Bay, is 1,660 mi. in length, measured to the head of its longest tributary, the Bow, and drains an area of 370,800 sq. mi., of which about 313,000 sq. mi. are in Canada. Its drainage basin embraces all the country, westward to the mountains, lying between the watersheds of Churchill and Athabaska rivers to the north and the Missouri to the south, and eastward to the

head-waters of Albany River and to within 50 mi. of the head of Lake Superior.

Its volume is computed to be 118,400 cu. ft. per sec. at extreme low water, measured just below Sipiwesk Lake and above the inflow of the large tributaries, Clearwater, Grass, and Burntwood rivers. The river is made up, by the union in Lake Winnipeg, of the Saskatchewan, Red, Assiniboine, Winnipeg, Berens, and many smaller rivers, and is augmented in volume after leaving the lake by receiving several large tributaries.

The water of the river is somewhat murky from suspended sediment, but gradually clears as it passes through the numerous lake expansions along its course, thus the amount of matter in suspension is 2.565 gr. per Imp. gal. below Lake Winnipeg and only 0.552 gr. near the mouth. The water of the Saskatchewan, near Cumberland, was found to contain 16.60 gr. of solid matter to the Imp. gal., while that of the Nelson, below Sea-river falls, contained 17.1 gr., and at its mouth, 12.528 gr.

The Churchill is 1,000 miles in length and has a drainage basin 115,500 sq. mi. in area. The water along part of the river's course is slightly murky. It contains above the mouth of Reindeer River, 7.96 gr. of dissolved solid matter to the Imp. gal. As is the case with the Nelson, the many lake expansions serve as settling basins, and the water, before reaching Hudson Bay, becomes quite clear. Its largest tributary, Reindeer River, flowing from Reindeer Lake and draining, as it does, part of the Pre-Cambrian peneplain, has very clear water, containing 2.02 gr. of dissolved solid matter to the Imp. gal.

Hayes River, with a length of 180 mi. and a drainage basin about 28,000 sq. mi. in area, drains a belt along the eastern edge of the area mapped; its water is remarkably free from suspended sediment, and carries only 0.878 gr. of solid matter to the Imp. gal.

The tract to the northwest, above referred to, sheds its water westerly into Athabaska Lake, to finally reach the Arctic Ocean by Slave and Mackenzie rivers.

Water-powers.—The total amount of power capable of being developed from the many falls and rapids which occur on the rivers within the area, is almost incalculable. Some of the rivers are of great volume and all, along parts of their courses, have rapid descents.

Of the rivers, the Nelson, by reason of its great volume and numerous falls, is the most important from the point of view of power development. Between Lake Winnipeg and Split Lake, a distance of about 230 mi., the river has a descent of 240 ft., and between Split Lake and the sea, 200 mi., a descent of 470 ft. The greatest fall occurs in the portions of the river between Cross and Sipiwesk Lakes, where there is a total descent of over 90 ft. in 28 mi., and between Gull Lake and the foot of Limestone Rapid, where the descent is 396 ft. in about 67 mi. There are a great many lake expansions along the course of the river, and between them, rapids and falls, to the number of fifteen or more, occur. Some of the falls offer excellent sites for water-power plants, and at several the vertical drop is considerable: at Ebb-and-Flow Rapid there is a fall of 11 ft.; at Whitemud Fall, 30 ft.; at Bladder Rapid, where the whole river flows in one channel for the first time after leaving Playgreen Lake, 11 ft.; at Over the Hill Rapid, 10 ft.; at Redrock, 10 ft.; at Grand Rapid, 20 ft.; at lower Gull Rapid, 50 ft.; and at Kettle, Long Spruce, and Limestone Rapids, drops of 50 ft. within a mile or so of distance.

When the great volume of the river is taken into consideration, amounting to 118,400 cu. ft. per sec. at low water, or about four times the volume flowing over the Chaudière Falls at Ottawa and one and a half times that at Sault Ste. Marie, it will be seen that the total amount of available power is very great.

Other high falls are Missi Fall on Churchill River, just below Southern Indian Lake, where the vertical descent is in the neighborhood of 20 ft.; Grand Rapids, at the mouth of the Saskatchewan, with a descent of nearly 100 ft.; a fall 30 ft. in height on Rapid River near the Churchill, and Manazo Fall on Burntwood River where the vertical drop is about 30 feet. In addition to these, falls and rapids almost innumerable occur along the courses of all the rivers and streams of the region.

In a report on the water-powers of Canada, published by the Commission of Conservation in 1911, an estimate is made of the horse-power available at a few of the falls and rapids within the district. On the Saskatchewan the estimate is made for only two of the rapids, namely:—

Cole Rapid, minimum h.p.	14,700
Grand Rapid, minimum h.p.	80,000

Trout Fall, Above Knee Lake, Hayes River.

On the Nelson River the horse-power is calculated for eleven rapids, and aggregates 6,859,000, divided as follows:—

	Approximate head, in feet.	Estimated horse-power.
Limestone Rapid	85	1,140,000
Long Spruce Rapid	85	1,140,000
Kettle Rapid	96	1,290,000
Gull Rapid	67	900,000
Birthday Rapid	24	320,000
Grand Rapid	20	270,000
Rapids above Sipiwesk Lake	31	416,000
Whitemud Fall	30	403,000
Whitemud Rapid	30	403,000
Ebb-and-Flow Rapid	11	148,000
Rapids above Cross Lake	45	605,000

The report for 1913 of the B.C.E.R. Company of Vancouver, B.C., shows a construction of 36.07 miles of new line, as follows:—Vancouver and suburban system, 9.66 miles; and Victoria city system and Saanich interurban line, 26.41. The total single track mileage of the system, December 31, 1913, was 370.09. During the last year the company has made the following additions to its rolling stock:—Three closed passenger motor cars, 43 feet 4 inches long; two combination passenger and mail motor cars, 38 feet; 30 freight box cars, 60,000 tons capacity, 40 feet; 30 freight flat cars, 60,000 tons capacity, 41 feet; three sweepers for city service, 28 feet 3 inches; 15 logging cars, 80,000 tons capacity, 42 feet.

PURE vs. IMPURE DRINKING WATER

The bearing which the impurity of water supply has upon the typhoid death-rate was indicated fairly well in an article by Mr. J. W. Ellms, filtration superintendent, Cincinnati Waterworks, in the December, 1913, issue of the American Public Health Journal. The article referred to conditions in Cincinnati before and after a purified water supply had been established.

For the three years preceding the installation of a purification system the typhoid death-rate averaged 53 per 100,000 population. For the five years following the purification of the water supply the death rates per 100,000 were 19, 13, 5.7, 11.4, and 7.1, respectively This represents an average reduction in the number of deaths from this disease of nearly 80%. The reduction in the cases reported is very nearly 85%, when estimated for this same period. Whether other sanitary reforms approximately coincident with the purification of the water supply have not played some part in the diminution of cases from this disease, the writer is not prepared to say; but there is little doubt that the principal agency has been the substitution of a pure for an impure drinking water.

A study of the accompanying table with a view to establishing some relation between the fluctuations in the typhoid death-rate and the quality of the water does not lead to any very positive conclusions. It immediately raises a question as to whether we really obtain any direct measure of the purity of a water in the usual bacterial examinations which are made. So far as the total number of organisms removed is concerned these results indicate a water of high purity. On the other hand, the presence of fecal or gas-producing organisms likely to be associated with the typhoid bacillus, as shown by the presumptive positive B. coli figures, would lead one to believe that the entire absence of these organisms in a water is by no means absolutely necessary as an indication of what experience has shown to be a safe drinking water. The reduction in the number of B. coli effected by filtration alone is evidently in the same proportion as that obtained in the reduction of the total number of bacteria. No selective action takes place in filtration, although there appears to be some such action when the disinfecting agent, calcium hypochlorite, is used.

So long as bacteriology is unable to furnish reliable and rapid methods for the isolation of pathogenic organisms in water, it will be necessary to rely on circumstantial evidence, such as has been furnished by the remarkable reduction of typhoid fever in Cincinnati, following the introduction of a purified drinking water. Since all those cases, in which the source of the infection remains untraced, may have been infected through agencies such as flies, shell-fish, raw vegetables, fruits and bacillus carriers, it reduces the probability of our present purified drinking water being a source of infection to practically zero.

Comparison of the Typhoid Fever Death-Rate With the Hygienic Quality of the Water Supply of Cincinnati, 1909 to 1912.

	1909.	1910.	1911.	1912.
Typhoid-fever death-rate per 100,000 of population	13	5.7	11.4	7.1
Percentage reduction from average death-rate for three years preceding introduction of filtered water supply	75	90	79	89
Average number of bacteria per c.c.—				
In river water	9,300	8,900	13,790	11,130
In filtered water	75	75	39	26
Percentage reduction of bacteria by purification	99.2	99.2	99.7	99.8
Yearly percentages of presumptive positive B. Coli results obtained in various amounts of the river and filtered water—				
In river water in 1 c.c.	93.2	91.0	85.3	93.5
In filtered water in 1 c.c.	1.0*	7.9*	5.2†	3.0‡
In filtered water in 100 c.c.	66.0*	65.0*	84.3†	51.6‡
Percentages of presumptive positive B. coli results in 100 c.c. of filtered water for the period of disinfection—				
Before disinfecting filtered water	....	....	88.9	89.3
After disinfecting filtered water	....	....	12.8	27.7

*No sterilizing agent used. †Disinfection with calcium hypochlorite for first three months of 1911. ‡Disinfection with calcium hypochlorite for first six and one-half months of 1912.

The project is being advanced by the Conservation Commission of New York State, which is akin to that of the Hydro-Electric Commission of Ontario. It is proposed to conserve, own, and develop, all the water powers in New York, so that eventually every factory in the state will be operated by electric energy and every house illuminated. It involves the further use of the Niagara Falls on the American side, the use of the Long Sault Falls, on the St. Lawrence, the Genesee Falls and the surplus water of the barge canal between Troy and Schenectady. Power on every stream in the state, will be taken over, and connected with the general plant so that in time the state, for many purposes, if not for all, will be independent of the coal interests.

Some time ago the company which supplies Berlin, Germany, with electric current, acquired lands with extensive deposits of lignite or brown coal at Bitterfeld 83 miles south of Berlin, and decided to build a power plant there to generate electricity for Berlin. Upon further exploration, however, the deposit of lignite turned out to be so vast that the company determined to build a plant large enough to supply all the towns within a radius of about 100 miles. The company thinks that it has an ample supply of lignite for nearly a 100 years. It will turn the coal directly into electricity; and this it proposed to do so economically that electricity will be used even for cooking and heating, because no other kind of fuel will be able to compete with it in price.

CONTENTS OF THIS ISSUE.

DEFECTS IN THE TORONTO BUILDING BY-LAW.

There is an annual waste of at least three-quarters of a million dollars in the construction of buildings in Toronto. This statement in Prof. Young's report to Judge Denton in connection with the investigation into the manner in which the work of the City Architect's Department is being conducted strongly substantiates the introductory reference to the structural features of the by-law being lacking in conformity with good engineering practice.

In May, 1911, a Citizens' Committee, composed of prominent representatives of Toronto's technical and business organizations undertook a careful study of the by-law which was then in force, and, after detailed comparisons with those of other cities, drafted a memorial to the City Council, urging a speedy revision, and outlining the important alterations, with proposals for their rectification. A year later the draft of a new by-law was completed by the city, in which a little of the undue severity of the old by-law towards reinforced concrete construction was removed. Much credit is due the Citizens' Committee for the modification of many of the restrictions. It is regrettable that the recommendations advanced in its memorial were not more extensively adopted.

During the past month the City Architect's Department has been under civic investigation, with a view to ascertain to what extent alleged inefficiency was founded upon fact. The investigation has included a consideration of the existing building by-law, and Prof. C. R. Young was retained as consulting engineer to interpret its chief unfavorable features. Some of the more important of them are enumerated in the article appearing on another page of this issue.

Striking among the defects of the present by-law is the discouragement which it presents to prospective industries. In addition to the remarkable lack of inducement held out to them to locate in Toronto, the high price of land and the unrelenting taxation are accompanied by another repelling force in this advanced cost of construction of buildings. Toronto, a most favorable location, geographically, barricades itself against desirable industries by measures that make conditions prohibitive to them.

PROMOTING EFFICIENCY IN SMALL WATER PURIFICATION PLANTS.

With our present development of the art of design and operation of water plants, and especially those plants which rely upon some form of chemical treatment, there exists an entirely inexcusable neglect of the equally important matter of daily operation. More particularly in the case of small plants do these discrepancies show themselves. In Mr. Letton's paper, appearing, in part, in this issue, some distinctive points are presented on the manner in which the typical small water purification system is inefficient, and some remedies worthy of note are suggested.

The operation of a small plant is undoubtedly a difficult problem. It requires the same class of skilled supervision that a large plant must have. Attention of this kind makes the cost of maintenance high, showing up very prominently when the operating costs of the plant are compared with those of another plant of 50 or 100 times the capacity. The appearance of excessive cost of supervision is prevented by employing untrained opera-

tives, and the logical result is neglect of those vital points which make the plant efficient.

In discussing the paper Prof. Geo. C. Whipple, of Harvard University, expresses his opinion to be that the safety of such plants must lie in the education of the low-salaried attendant and in the selection of such sources of supply that irregularities in operation will produce less disastrous results than in the case of larger plants where a higher grade of supervision is possible. To secure the better appreciation by the operator of the general principles of sanitation, and a better understanding of the work which a particular filter is capable of doing, the supervision of the state authorities should be not so much punitive as pedagogical.

Another remedy that has been suggested is the establishment of laboratories at convenient points to serve two or more small plants. Another is the employment of a consulting engineer in connection with operation as well as with installation. A third advocates a capable supervising engineer over several small systems on a co-operative working agreement.

The importance of efficiency in a plant of small capacity is as great to that community as it is in the case of any other plant. The question of placing water supply problems in every case in the hands of those who can deal scientifically with them has not received the attention it deserves. It is becoming more and more evident that the engineer must work in conjunction with the chemist and the bacteriologist in solving them. For small municipalities, therefore, there appears to be much of value in co-operation, each contributing toward the maintenance of such services.

PRESERVATION OF REFERENCES.

The engineer who is seeking a new position and who is fortunate enough to possess a valuable set of creditable and convincing references should consider them in the same light as he would any other property which is of value. The man who finds himself out of employment hastens, too often, to launch applications promiscuously, enclosing with them his original testimonials, and when they thus pass out of his possession they do not always return.

There is no advantage to be derived from a transmittal of the original references with letters of application for positions. Carbon copies fully convey the desired information, and do not entail a serious loss if they are mislaid. Moreover, an employer whose custom it is to place dependence upon such evidences of ability, training, character, etc., will see to it that they are bona fide before converting the applicant into an employee.

At first thought this may appear a trivial subject, but we are prompted to impart the advice by the experience of our Employment Bureau. Letters are being received continuously with the original references enclosed. Other applicants regret inability to furnish references owing to their having been previously lost or to their being out "on duty" in connection with another application. Frequently inquiries are received as to the safe keeping of these commodities.

The Canadian Engineer Employment Bureau keeps a permanent record of the professional standing and experience of its applicants for positions. Testimonials are preserved therewith in order to render the service more complete. Carbon copies are all that are required, it being understood that the original of each is in the proper possession of the applicant in order that he may have immediate recourse to them when an employer is disposed to consider original references only.

LETTER TO THE EDITOR.

THE BILLING'S BRIDGE (OTTAWA) DESIGN.

Sir,—It was not the writer's intention to enter into a controversy with anyone about the Billing's bridge at Ottawa. My only intention was to draw attention to the all too prevalent practice of building light floors on highway bridges. Mr. Henham, in his letter in *The Canadian Engineer* of February 19th, has made several statements which are so far removed from the facts that I feel obliged to correct them.

In the first place, I cannot agree with him when he uses $\frac{w\,l^2}{12}$ as the formula for the bending moment. I have never seen a specification of any authority which would permit such use. The general formula specified for continuous beams is $\frac{w\,l^2}{10}$, or, as some specifications state, "$\frac{8}{10}$ of the bending moment figured as a simple beam." (See clause 14, page 9, of the General Specifications for Concrete Highway Bridges of the Ontario Highway Board.)

In the second place, he states that "dividing the bending moment by the moment of resistance of the steel gives the sectional area required per ft. of width as 0.6 sq. in." I fail to understand what Mr. Henham means by this.

If the slab were designed properly, the moment of resistance of the steel would equal the moment of resistance of the concrete, and also the bending moment in the slab. This condition of design is obtained when the bending moment, M, = $108\ bd^2$ (where b = width of beam and d = effective depth), and when .78% of bd is the area of steel supplied. The above figures are only true when the compressive value of the concrete is assumed at 650 pds. per sq. in. and the tensile value of the steel is 16,000 pds. per sq. in. These are the most common values used. The deductions of these formulæ are to be found in any up-to-date text book on reinforced concrete. The bending moment as given by Mr. Henham is 3,500 ft. pds., or rather 4,200 ft. pds. when we use the formula $\frac{w\,l^2}{10}$. For this moment we require a slab of 6¼ inches effective depth.

In the third place, I cannot see how Mr. Henham can figure the truck load as 3,800 pds. per ft. of width. Taking his distribution of loading, i.e., 1.16 ft. × 1.83 ft. (the 1.83 dimension at right angles to stringers), this gives, in my opinion, a loading of $\frac{8{,}000}{1.16} = 7{,}175$ pds., and this load is uniform on the slab for width of 1.83 ft. The resulting bending moment is 4,630 ft. pds. and requires a slab of 6½ in. effective depth.

The loading Mr. Henham used is all right, the difficulty seeming to be in the design of the slab.

E. M. PROCTOR.

Toronto, February 24th, 1914.

The eighth annual dinner of the Association of Dominion Land Surveyors will be held at the Chateau Laurier, Ottawa, on March 3rd, at 8 p.m.

THE STRUCTURAL REQUIREMENTS OF THE TORONTO BUILDING BY-LAW OF 1913

BASED ON A REPORT SUBMITTED FEBRUARY 20th, 1914, TO JUDGE DENTON IN CONNECTION WITH THE INVESTIGATION OF THE CITY ARCHITECT'S DEPARTMENT, TORONTO.

By C. R. YOUNG, B. A. Sc., M. Can. Soc. C.E.
Assistant Professor of Structural Engineering, University of Toronto.

THE structural requirements of the Toronto Building by-law are in many respects not in conformity with good engineering practice. It is true that more conservative by-laws may be found, but these can in no sense be said to afford proper standards for the judgment of any building by-law under review. For the records of the best engineering practice one must turn to the published specifications of great engineering organizations, or of governments, or of railways, or to the writings of the leading structural engineers and to those of the more recent building codes which have been revised by structural experts or with their co-operation. It is entirely erroneous to regard building by-laws in general as expressive of good practice, for not only are they generally several years behind the times, but they have often been framed by one man and not infrequently show the handiwork of lay bodies who have the deciding voice in the inclusion or rejection of technical regulations. As compared, then, with what is best in modern construction, the Toronto by-law is faulty in many particulars.

No attempt has been made to present an exhaustive discussion of the shortcomings of the by-law. A few of the striking transgressions of good practice have been chosen for comment and an effort has been made to show in so far as possible, without undue labor, the practical outcome of the erroneous provisions.

FIREPROOFING OF EXTERNAL COLUMNS.

Sub-section 44, page 22.—An instance of undue severity is afforded in the requirement of *nine* inches of brickwork plus *one* inch of cement grout on the outside of iron and steel columns in external walls. No better proof of this is needed than the fixing in the same sentence of the protection for the inside of such columns at four and one-half inches of brickwork, or approximately one-half as much as for the outside, in spite of the fact that the temperature of a fire inside a building is much higher than that of a fire outside of it. If such were not the case, articles to be heated would be placed in an open fire rather than in a confined one.

A further admission of the sufficiency of four and one-half inches of brickwork for fireproofing is contained in the same sub-section, in specifying this thickness for the outer sides of beams or girders carrying the external walls. That there is no chance of a fire affecting steelwork situated 4½ inches from the surface of a brick casing is evident from the fact that the outer edges of the flanges of these beams and girders may project to within two inches of the outer surface. If 5½ inches of protective covering will not prevent a fire from softening the metal in external columns, certainly 4½ inches will not prevent the same fire from endangering the wall girders. With their collapse the lateral support of the wall columns would be removed and the columns would fail by buckling in the direction of the wall. The integrity of the building at one point thus depending upon 4½ inches of fireproofing, what reason is there for requiring 10 inches at a point subjected to the same destructive agency?

Perhaps the most convincing evidence of the sufficiency of 4½ inches of brickwork as fireproofing for external columns is seen in the adoption of a less thickness by the City of San Francisco in the revision of its building code after the great earthquake and fire and after having placed before it the conclusions of a special investigating committee of the American Society of Civil Engineers. For fireproofing all around such columns the requirement of the San Francisco code is but two and three-quarters inches of brick set in cement mortar, although the hazard in that city is much greater than in Toronto, due to the possible combination of earthquake and fire.

It is of interest to note further that Chicago, in its new building code, which was framed by a commission with large expert representation on it, permits four inches of brickwork all around external columns, while the City of St. Louis permits three inches.

The monetary loss involved in the excessive fireproofing of external columns would, for a 10-story building, say, 80x100 ft., amount to approximately $2,500.

CURTAIN WALLS.

Sub-section 44, page 23.—Since curtain walls carry only their own weight and usually for only one story in height, in certain cases it is absurd to require 14 inches of brickwork for them. In many industrial buildings where the curtain walls cover only 3 or 4 feet of vertical space immediately below the windows, the wastefulness of building in 14 inches of brickwork or plain concrete is apparent. In all buildings the space between the top of a window in one story and the bottom of a window in the next story above might safely be filled in with any material equivalent to wire glass in fire-resisting properties.

The contention that heavy brick walls are needed to prevent falling walls from breaking into a building is groundless, for no matter how heavy the curtain walls might be, falling walls could expose the interior of the building to flames by breaking through the windows. Nor is the relative smallness of the window areas any safeguard, for there is nothing to prevent the builder from constructing, and, indeed he often does construct, the whole space between columns from one floor to another of glass, but if he wishes to use brickwork at all it must be 14 inches in thickness. From this it follows that, according to the Toronto building by-law, one thickness of glass has a protective value as great as 14 inches of brickwork or plain concrete.

That a thickness of 9 inches of brickwork under and over windows is adequate should follow from the fact

that 9-inch walls are permitted by the by-law for severer conditions of loading than exist in curtain walls. Perhaps the best example of this is the use of 9-inch walls for the external, load-bearing walls of dwellings two stories in height. While curtain walls sustain only their own weight for one story of height, these bearing walls carry the entire weight of the floors and roof in addition to their own weight, for two stories in height.

A further abuse in the matter of curtain walls exists in the requirement that they shall be increased by 4½ inches in thickness below the uppermost 75 feet of the building and by an additional 4½ inches for each 60-ft. section below that. For the same story heights, curtain walls in the lower stories carry no more load than those in the upper stories and the thickening is no guarantee that falling walls may not break through into the building. Windows are allowed on any side of a building and may fill entire panels of wall space, as they very often do for the first story or two above ground.

The practical effect of this indefensible curtain wall specification is to increase the weight and size of the wall girders, wall columns and wall footings, to add a great deal of unnecessary brick, concrete or tile to the walls and to reduce the available floor space. Actual estimates show a financial waste for this reason alone in representative buildings running into thousands of dollars. For a 10-story building, say, 80x100 ft., the waste, neglecting the value of lost floor space, is from $7,000 to $10,000. In a memorandum submitted by Mr. A. H. Harkness, of Harkness and Oxley, consulting engineers, to Judge Denton in the recent enquiry into the City Architect's Department, it was shown that the cost of the Dominion Bank Building was increased by $14,200 by reason of the requirement that curtain walls shall be thickened below the top 75 feet of the building. Of this, $9,200 was for extra masonry and $5,000 for extra steel. Mr. Harkness also calculated that the loss in *annual* rental value because of the reduction in available floor space is $5,900. Capitalized at 6 per cent., this amounts to an investment of approximately $100,000. For the Canadian Pacific Railway Building, the cost of excess masonry was $6,150 and of excess steel $3,900, making in all, $10,050. The loss in annual rental value is $5,150, which when capitalized represents an investment of about $85,000. In the case of a large building in another city where the same antiquated regulations are in force the waste of steel alone involved in the thickening of curtain walls below the top 75 feet was 800 tons with a value of $45,000, not counting the cost of the masonry nor the value of the lost space.

SAFE LOADS ON BRICK WORK AND MASONRY.

Sub-section 19, page 44.—According to tests made in the University of Toronto laboratories, the average crushing strength of ordinary brick masonry laid in lime mortar is 67 tons per square foot, and when laid in cement mortar, 122 tons per square foot. In view of these results it is interesting to note the following safe loads per square foot specified for brick masonry in the Toronto by-law:

Kiln run bricks laid in lime mortar	4 tons
Ordinary brick laid in Portland cement mortar..	6 tons
Hard brick laid in lime mortar	7 tons

It is thus evident that in Toronto the average factor of safety required for ordinary brick laid up in lime mortar is 17, and for ordinary brick work with Portland cement mortar no less than 20. For walls, piers or other like supports a factor of safety of over 10 or 12 is uncalled for and its requirement results in a great waste of material.

A striking commentary on the lowness of the allowable pressures on brick masonry is afforded by comparing them with the following permissible loads per square foot on soils established by the by-law:

Gravel and coarse sand, well cemented	8 tons
Dry, hard clay	4 tons
Sand, compact and well cemented	4 tons

From the above two tables it is evident that a well compacted gravel or coarse sand is considered to be capable of sustaining more load than any one of the three grades of brick masonry mentioned and twice as much as kiln run bricks laid in lime mortar.

It is of interest to note, too, that with respect to the load that would result in dangerous, crack-producing settlements, the factor of safety involved in the above permissible soil pressures is from 2 to 3, while the factor of safety required on brick masonry is from 17 to 20.

A study of the available records of tests of brick masonry indicates that the specified safe loads on brick work might, with perfect security, be increased 33 per cent., and still allow a factor of safety of at least 12. The waste in brick piers, as at present constructed, is therefore 33 per cent.

The safe pressure on walls and piers of concrete is also much too low and should be increased.

CAST IRON COLUMNS.

Section 16, page 74.—In view of the results of tests on full-sized cast iron columns, and the large element of uncertainty attending their manufacture and use, the safe loads specified for these columns in the by-law are undoubtedly excessive. A factor of safety of less than four, which the by-law permits in the case of the most heavily loaded columns is manifestly insufficient when it is remembered that with the far more reliable material, structural steel, the factor of safety demanded is four. No acknowledged authority known to the writer sanctions a factor of safety of less than 5 for cast iron columns and for this reason the safe loads allowed by the by-law should be reduced for certain columns by over 20 per cent.

PLATE GIRDERS.

Sub-section 4, page 77.—The provisions of the by-law respecting plate girders are not in accordance with good engineering practice. In order to satisfy them, girders must be made considerably heavier than would be required for the support of the same loads in most of the railway and highway bridges of the country. Thus, a plate girder constructed according to either the specifications of the Canadian Pacific Railway, the Grand Trunk Railway, the Canadian Northern Railway, the Dominion Government, the Ontario Government, or the Canadian Society of Civil Engineers would not be acceptable for use in a building in Toronto. The absurdity of this is still more apparent when it is remembered that a bridge girder must withstand large and uncertain stresses due to impact and vibration and is subjected to rapid corrosion from moisture and locomotive gases, while a building girder carries quiescent loads and is but little exposed to corrosion. Another remarkable fact is that plate girders in bridges built by the Works Department of the City of Toronto, and conforming as they do to the above-mentioned authoritative specifications, would not pass the city building by-law, and would be regarded as unsafe by the City Architect's Department. On the other hand, if all the city bridges are safe, there is an

unpardonable waste of material in the girders which the by-law requires to be used in buildings.

Some indication of the unreasonable exactions of the by-law in this particular may be had from the following estimates made by the writer. A girder built in accordance with the by-law to carry a load of 100 tons would, according to the specifications of the great railways, the Dominion and Ontario Governments, the Canadian Society of Civil Engineers and the Works Department of the City of Toronto, be entirely safe for a load of 122½ tons. A girder designed for 200 tons according to the by-law would be safe for a load of 238½ tons. To put the matter generally, girders designed in conformity with the Toronto building by-law will carry with the factor of safety demanded by the railways, for example, from 17 to 35 per cent. more than they are at present permitted to carry.

The waste of material involved in following such an antiquated plate girder specification varies with the capacity and span of the girder but lies normally between 8 and 10 per cent. Plate girders as used in the buildings of Toronto thus cost from 8 to 10 per cent. more than they should. In the new Dominion Bank Building at the corner of King and Yonge Streets, $1,200 was absolutely wasted on this one item alone. In the new Royal Bank Building the corresponding loss will be $1,400, in the Toronto Technical School it will be $2,100, and in the new Methodist Book Room it will be about $2,200. From these, and other facts it is apparent that not less than $25,000 is expended every year in putting excess material into plate girders, which, as far as use is concerned, might quite as well be thrown into the sea.

SAFE LOADS ON TIMBER COLUMNS.

Section 18, page 80.—The safe loads on timber columns are much lower than are sanctioned by almost any good specification that might be named, and do not correspond at all to the results of actual tests. For example, a long-leaf yellow pine column 12 x 12 ins. and 15 ft. long and which would not be allowed to carry more than 52 tons by the Toronto by-law would be considered entirely safe for a load of 61 tons in Boston, Buffalo or Minneapolis or a load of 64 tons in Chicago, or a load of 70 tons in Baltimore or in a structure built by the Works Department of the City of Toronto 65 tons, or in any structure built in accordance with the requirements of either the Dominion or Ontario Governments a load of 68 tons. It is not remarkable that a column which a Toronto contractor must put into a building to carry a certain load, would, if put into a civic bridge in the same city, be allowed to carry a load of 24 per cent. greater, or if put into any bridge sanctioned by either the Dominion or Ontario Governments a load 31 per cent. greater? And this is not by any means the worst case, for with columns of greater slenderness the exactions of the by-law are still greater.

The practical result of this is that the cost of the columns of mill construction buildings, is on an average 25 per cent. greater than it should be.

FLOOR LOADS.

Section 23, page 86.—The specified live loads for which floors are required to be designed are in a number of cases greater than are at all likely to occur in the life of the buildings concerned, and in the interests of economical construction some reduction in such loadings should be made. A careful comparison of the prescribed loads set forth in the by-law with the results of actual investigations, with recent authoritative specifications and with such building codes as have been revised recently, indicates excessive requirements in the Toronto by-law. Two instances will suffice to show the need of careful consideration of the present specified loadings.

Paragraph d, page 87.—It has been clearly shown by careful determinations of the maximum loads on the floors of office buildings, that the loads in the offices themselves, above the ground floor, will ordinarily never exceed 40 to 50 pounds per square foot. A thorough investigation of this kind was made by Messrs. C. H. Blackall and A. G. Everett in three large office buildings in Boston. For each room the weights of the furniture and contents and of the greatest number of people known to have been in it at any one time were taken, and the greatest load thus found in any one office was 40.2 pounds per square foot. In only 12.4 per cent. of the offices was the maximum known floor load in excess of 25 pounds per square foot and in only 26 per cent. was it over 20 pounds per square foot.

In the light of these and other observations which might be cited, a floor load in offices of 75 pounds per square foot as is required in Toronto appears to be extravagant and should be reduced to 50 pounds per square foot. Partitions should be considered as an additional load.

As an instance of the adoption of rational floor loads for office buildings, the recently revised building code of the City of Chicago places the loads at 50 pounds per square foot *for all floors and corridors* with partitions extra.

Paragraph f, page 87.—A consideration of the character of the loading on school room floors and of the conditions existing in such buildings leads to the conclusion that 75 pounds in rooms and 100 pounds in corridors and lobbies are excessive live loads. A mixed throng of children averaging, perhaps, 75 pounds each in weight cannot impose upon a floor any such load as a throng of adults averaging 150 pounds each. Investigations will show that while children weigh on an average half as much as adults they occupy two-thirds as much space, and therefore the intensity of loading due to a throng of children should not be over three-quarters of that due to a throng of adults. If, then, a load of 75 pounds per square foot represents, as the by-law assumes, the probable weight of a mixed crowd in the main entrance halls of hotels, apartment houses, tenements and boarding schools and in the corridors and halls of office buildings, surely it should be an adequate allowance for the live load in the corridors and lobbies of schools where the typical crowd will weigh 25 per cent. less. Nevertheless, the by-law requires the latter to be figured for 100 pounds. In the school rooms, where the seats are generally fixed, a load of three-quarters of that specified for the corridors and lobbies, or, say, 60 pounds per square foot should be entirely adequate.

The propriety of these loads for schools is evidenced by the fact that the framers of the new Chicago code fixed the maximum loads for the assembly halls, corridors and stairs of schools at 75 pounds per square foot and for all other parts 40 pounds per square foot.

REDUCTION OF LIVE LOADS ON GIRDERS.

Since a girder can receive its maximum load only when the beams which it supports are fully loaded, it follows that a much larger area must be covered for the maximum load on a girder to arise than it is necessary to cover for the production of the maximum load on a floor beam. In an average case these areas are as three

to one, and for many floors the area to be covered with the stipulated floor load before a girder can receive its maximum stress is six or seven hundred square feet. Manifestly, the probability of an area of this size being *entirely* covered with the full floor load is very small. Even in the case of storage warehouses, where the probability is greatest, a considerable percentage of floor space must be left for aisles. The requirement of the Toronto by-law that girders must be figured for the same floor load per square foot as beams are figured is therefore entirely indefensible.

The completely covered proportion of the area sending load to a girder is variously estimated. Mr. Gunvald Aus, the consulting engineer on the world's greatest building—the Woolworth Building—favors making it two-thirds. A considerable number of cities fix it as substantially less than the full area. Chicago, Boston Philadelphia, Pittsburgh, Cleveland, St. Louis and San Francisco may be cited as instances. The reduction fixed by the building codes of these cities for most types of buildings ranges from 10 to 20 per cent., with an average of 15 per cent. That is, girders in most buildings, according to the codes mentioned, would be figured for only about 85 per cent. of the full possible floor load. The only kind of building for which the full floor load is required to be figured in the cities named is the warehouse or heavy mercantile building, and not even for these in all cases. The writer is thoroughly convinced that the calculation of girders for more than 85 per cent. of the full live load, except in the case of warehouses, is an extravagant and unnecessary procedure.

The practical result of the severe requirements of the present by-law with respect to girders has been estimated by the writer for different types of buildings and is as follows: For office buildings the increased cost of girders is approximately 4½ per cent.; for stores it is about 5 per cent.; while for factory buildings it is about 5½ per cent. The effect upon the cost of the beams, girders and columns is to increase it by from 1½ to 2 per cent. For a building in which these structural parts cost $100,000, the waste involved by this regulation of the specification alone is from $1,500 to $2,000.

REDUCTION OF LIVE LOAD ON COLUMNS.

Section 12, Sub-section 1, page 38.—Since the live load borne by a column in any story is derived from an area very large in comparison with the area tributary to either a floor-beam or a girder, a smaller floor live load should be used for figuring columns than for figuring floor-beams or girders. Admission of this principle is made in the by-law, but the probable maximum load, particularly for columns a long way down from the top of the building, is greatly overestimated.

Thus, to illustrate, in a typical office building, a column in the 12th story down from the roof must be figured for 76 per cent. of the maximum loads to be carried by the roof and all the floors above while most structural engineers consider 80 per cent. of the full specified live load as adequate for girders and even many of the building by-laws require only 85 per cent. of the full floor load for girders. The absurdity involved is most evident when it is remembered that the area which must be covered for a *full* load on the column mentioned is 24 times that which must be covered for a full load on a girder. Surely if not more than 80 or 85 per cent. of an area delivering load to a girder is likely to be fully loaded, an estimate of a full load on 76 per cent. of an area 24 times as great is altogether illogical and unsound.

The unreasonable demands of the by-law in this particular may be shown in still another way. For the column in the twelfth story down from the roof, after allowing for a full snow load on the roof and the weight of furniture, office equipment, safes, etc., on all floors, no less than 5,000 people would, in an average case, need to be massed about this column on the area contributing load to it in order to realize the load for which the Toronto by-law would require the column to be figured. The writer has estimated that even in a building with first-class elevator equipment it would take 3½ hours to distribute these 5,000 persons to the various floors, with none descending.

While the exacting character of these regulations respecting column live loads is less striking for columns nearer the roof than for the one forming the subject of the illustration, the waste involved is considerable, and what is more, entirely indefensible.

Corroboration of the conclusions expressed above may be had in the investigations of Messrs. Blackall and Everett, to which reference has already been made. In the three office buildings examined, while the greatest live load found in any room on any floor in any building was 40.2 pounds per square foot, the average of the maximum loads for all floors did not exceed 17 pounds per square foot in any one of the three buildings. It thus appears that the average maximum for *all* the floors is less than one-half of the maximum probable load on any one floor, and that columns in the lower stories of buildings, except storage warehouses, need not be designed for more than one-half of the specified maximum loads on the floors above. The proportion should, of course, gradually increase to 100 per cent. as the roof is neared.

That a much greater reduction of live loads on columns than is permitted in Toronto is sanctioned by good practice may be gathered from a study of the opinions and specifications of eminent structural engineers, and of the most recently revised building codes. Some years ago a notable paper on "The Structural Design of Buildings" was presented to the American Society of Civil Engineers by Mr. C. C. Schneider, one of the three engineers who are rebuilding the Quebec Bridge, and from the discussion of this paper by the ablest structural engineers of the continent it was shown that engineers are unanimous in their approval of live load reductions for columns much greater than are allowed by the Toronto by-law. This opinion was embodied in the authoritative "General Specifications for the Structural Work of Buildings" subsequently published by Mr. Schneider. Turning to the building codes, it is found that Chicago, Boston, Baltimore, St. Louis, Minneapolis, Providence, and San Francisco all allow greater reductions than are permitted in Toronto.

As a result of the severity of the Toronto by-law in the matter of column live loads the cost of columns in buildings over five stories in height is increased from 3 to 10 per cent. and the effect on the cost of the beams, girders and columns of the building is to increase their cost from three-quarters of one per cent. to two per cent. For a building in which these parts cost $100,000 for this particular item alone the waste involved would be from $750 to $2,000, depending on the number of stories.

REINFORCED CONCRETE CONSTRUCTION.

Pages 154 to 183.—Objection is made to the provisions of the present by-law respecting reinforced concrete on the following general grounds:

(1) The strength and reliability of this form of construction is underestimated.

(2) The necessary assumptions of design are, in a number of cases, not in accordance with those adopted by the best authorities.

(3) The regulations are incomplete.

That the section of the present by-law under discussion is not in accord with the best engineering practice of the day might easily be ascertained by any impartial technically-trained person. To do this it would merely be necessary to consult the recent literature of reinforced concrete, for example, the so-called Joint Committee Report, the most authoritative statement yet made in America of what constitutes good practice in reinforced concrete design and construction. This document is the result of the deliberations for a period of ten years of a Joint Committee formed of committees of the American Society of Civil Engineers, the American Society for Testing Materials, the American Railway Engineering Association and the Association of American Portland Cement Manufacturers. So satisfactory and manifestly sound are the regulations of this report that other large technical organizations have adopted almost identical specifications. At the present time the Canadian Society of Civil Engineers has in course of preparation a specification for reinforced concrete agreeing, in the main, with that of the Joint Committee.

With the authority of the great engineering societies behind them many cities of the United States have quite naturally adopted regulations for reinforced concrete closely conforming to the recommendations of the Joint Committee Report. In one case a state—Pennsylvania—has taken such a step.

In judging the character of the Toronto building by-law, with respect to the regulations of reinforced concrete construction, it is possible, therefore, to make a comparison with the provisions of a number of other building by-laws, with the assurance that the relation of the Toronto by-law to good practice will thereby be fairly disclosed. Such a comparison shows that the Toronto regulations are much more exacting than those adopted by most of the cities that have recently revised their building codes. New York, Chicago, Pittsburg, Detroit, Cleveland, St. Louis, and Minneapolis approve as perfectly safe reinforced concrete structures which, in some cases, are considerably lighter than those permitted in Toronto, and these cities are by no means the only ones that might be named.

It is of interest to note, also, that reinforced concrete structures built according to the specifications of the Ontario Government and the Works Department of the City of Toronto are considerably lighter than those which would result if the Toronto building by-laws were followed.

On account of the difficulty of estimating the relative severity of reinforced concrete specifications by comparing them, point by point, the writer has made careful designs and estimates of quantities and costs for an interior panel of a reinforced concrete building in accordance with the Toronto building by-law and three other specifications. The panel and its loading were so chosen that as many as possible of the important provisions of the various specifications would be brought into operation. To effect this a panel 21 x 21 feet, with beams heading into the girders at the third points and carrying a superimposed load of 250 pounds per square foot, including the floor finish, was adopted. As a result, it is believed a fair indication of the average requirements of each specification is brought out.

The three specifications chosen for comparison, in this way, with those of the Toronto by-law were the Joint Committee Report, and the recently-enacted reinforced concrete regulations of the New York and Chicago building codes. More reinforced concrete structures in America are designed to the Joint Committee regulations than to any other, or perhaps to any half-dozen other specifications, and because of the size of New York and Chicago their regulations should be regarded as possessing some weight, particularly since they represent very recent work on the subject. Taking the Joint Committee design as the standard, and letting quantities and costs for it be represented by 100 for each item, the following statement represents the comparative results of actual detailed designs, the assumed unit costs being the same in all cases:—

Comparison of Quantities and Costs for a Typical Floor Panel.

Specification.	Volume of concrete.	Weight of steel.	Area of forms.	Costs.
Joint Committee, 1913.	100	100	100	100
Chicago, 1911	94.4	101.1	98.7	97.9
New York, 1911	95.1	109.0	95.8	100.5
Toronto, 1913	116.0	99.9	105.1	109.3

It should be pointed out that this table does not indicate the full measure of severity of the Toronto regulations. The figures given do furnish a fair comparison of the cost of reinforced concrete floors and one tier of columns, but when the effect of increased load on the columns below and on the footings is taken into account, the much heavier dead load applied to the columns at *each* floor results in further increased quantities and costs. It is, therefore, very close to the truth to say that the exacting nature of the provisions of the Toronto Building By-law with respect to reinforced concrete, apart from all other considerations, makes the cost of the reinforced concrete work in buildings at least 10 per cent. more than it should be. In this city during the course of one year there is probably a million dollars worth of such work done, and on this basis at least $100,000 is taken out of the pockets of owners to no useful purpose whatsoever. If the effect of other objectionable sections of the by-law on the reinforced concrete portions of buildings be considered, the waste is very much increased.

On the ground of incompleteness a number of criticisms might be made of the sections of the by-law relating to reinforced concrete. One of these is prompted by the fact that no specification whatever is included for a form of reinforced concrete construction which has found long and satisfactory use in the United States, and which possesses marked advantages for long spans and heavy loads. This is the girderless floor or flat-slab type of construction. As a result of the omission of any reference to it in the by-law, and the absence of definite regulations concerning it, little effort has been made to introduce the system here, to the financial loss of those who erect reinforced concrete buildings.

THE PRACTICAL OUTCOME OF THE DEFECTS IN THE PRESENT BY-LAW.

One obvious result of the exactions of the present by-law is the high cost of building. In steel construction, experience has shown that the *total* cost of buildings is from 3 to 10 per cent. more than it should be. Reinforced concrete buildings cost at least from 5 to 15 per cent. more than they would if designed to a reasonable and at the same time perfectly safe specification. The waste involved in mill construction buildings is from 5 to 10 per cent. of the total cost. Taking all classes of buildings into consideration, it is on the side of safety to say that *there is an annual waste in the construction of buildings in Toronto of at least three-quarters of a million dollars.*

Other results which follow the high cost of building are the location of industries outside of Toronto and the limitation of building projects. Of these the Citizens' Committee, which made a thorough study of the defects of the by-law in 1911, found a number of instances, some of which were recorded in the Memorial addressed to the Mayor and Board of Control in May, 1911.

A most deplorable result of the present objectionable by-law is the premium which, in effect, it places on non-fireproof construction. Under average conditions outside of Toronto fireproof buildings can be built for from 10 to 15 per cent. more than mill construction buildings, but in Toronto the difference in cost is from 15 to 20 per cent. Rather than pay this, therefore, owners prefer to erect non-fireproof buildings and pay higher insurance rates.

SHIPBUILDING IN 1913 IN GREAT BRITAIN.

The following table and comparisons showing the general progress in shipbuilding in 1913, and particularly the advance shown in the United Kingdom, are extracted from an article of considerable length in *The Contractors' Chronicle*.—

"For the year 1913 record productions are shown in the leading shipbuilding centres of the United Kingdom. Remarkable progress has been made in other countries, but British yards continue to provide their old-time proportion of the world's tonnage. Returns of vessels launched in 1913 show a total in number of 3,936, and in measurement of 4,267,166 tons, while there is recorded a total of 4,924,799 i.h.p. In all these figures there are increases as compared with 1912—in number of vessels 325, in measurement nearly 500,000 tons, and in machinery over 677,000 i.h.p. In the United Kingdom there were launched 1,474 vessels of 2,263,933 tons, and there were manufactured marine engines of 2,661,260 i.h.p. These figures show increases over those of 1912 of 120 vessels, 183,762 tons and 388,994 i.h.p. Of these increases the credit for the additional number of vessels is due wholly to England, and that for the increased tonnage and horse-power principally to Scotland. England produced 133 vessels, 95,071 tons and 135,460 i.h.p. more than in 1912, while Scotland produced 15 fewer vessels, but 121,523 tons and 233,485 i.h.p. more, while Ireland turned out 2 vessels more, 32,832 tons less and 20,050 i.h.p. more than in the previous year. Comparing the work of the United Kingdom with that of other nations, we find that the United Kingdom produced just about one-third of the total number of vessels, nearly 320,000 tons measurement more than all other countries combined, and nearly 420,000 horse-power more. The apparent discrepancy in the lower number of vessels is explained of course by the fact that the vessels built in the United Kingdom are of much greater average size than those built abroad. The following table shows briefly the shipbuilding work of the world for the years 1913 and 1912:—

	1913.			1912.		
	Ves.	Tons.	I.H.P.	Ves.	Tons.	I.H.P.
England	945	1,322,306	1,300,445	812	1,227,235	1,263,086
Scotland	505	800,711	1,148,[illegible]5	5[illegible]	688,188	914,740
Ireland	24	131,016	11[illegible],500	22	164,748	9[illegible],540
U.K. totals	1,474	2,263,933	2,661,260	1,354	2,080,171	2,272,[illegible]66
Dominions	280	59,025	20,662	208	36,578	17,022
Foreign	2,182	1,944,158	2,242,877	2,049	1,648,310	1,957,606
Grand totals	3,9[illegible]6	4,26[illegible],11[illegible]	4,924,799	3,611	3,765,059	4,24[illegible],794

By March [illegible] the new factory built [illegible] Peterborough, Ont., by Henry Hope and Sons, Limited, will be ready for the manufacture of wrought steel sash, roof glazing and skylights. The building is all brick and steel, 200 feet long by [illegible] feet wide, and shows well the adaptability of steel sash and saw-tooth roof to the modern factory. Alex. Young, the superintendent and manager of the company, states that the machinery for this plant was specially designed, and embodies the latest improvements. The factory is fitted throughout with carrying tracks and travelling cranes.

REPORT OF THE TORONTO RAILWAY COMPANY FOR 1913.

Operation during 1913 was most favorable, according to the 22nd annual report of the Toronto Railway Co. The gross earnings of the company for the past year were \$6,049,018; charges for operating, maintenance, etc., \$3,123,308; and net earnings, \$2,925,710. From the net earnings was deducted the sum of \$2,158,472, distributed as follows:—Dividends, \$879,958; and bond interest, etc., \$188,806.

The gross passenger earnings show a big increase, these earnings amounting to \$5,980,695, compared with \$5,367,502 for 1912, an increase of \$613,193. The various charges against these earnings for operating, maintenance, etc., amounted to \$3,123,308 or 52.2 per cent. of the passenger earnings. The payments made to the city of Toronto shown in the report amounted to the sum of \$1,089,708, which, when compared with the payments made during the previous year, shows an increase of \$147,659.

Heavy expenditures on capital account were made amounting to \$1,064,857. In addition to various extensions and improvements to certain of the company's shops, car houses, etc., the following buildings were erected:—A storage battery building was completed in connection with the Harrison Street sub-station; a sub-station (No. 4) was erected in Queen Street East, opposite Logan Avenue; and a paint shop was built on Queen Street East on property running from Queen Street to Eastern Avenue. Large expenditure was made in the installation of a storage battery plant in the Harrison Street building, in the construction of additional rolling stock and the purchase of electrical equipment for same and in the extension of the track and overhead system in different sections of the city.

The growth of the business of the company since 1903 is clearly shown in the following table:—

	1903.	1913.
Gross income	\$2,172,087.85	\$6,049,018.92
Operating maintenance, etc.	\$1,200,823.39	\$3,123,308.55
Net earnings	\$ 971,264.46	\$2,925,710.37
Passengers carried	53,055,322	151,236,925
Transfers	18,654,344	63,083,118
Percentage of charges, etc., to passenger earnings	55.3	52.2

Compared with 1912 also, all these items show a large increase, with the exception of the percentage of charges to passenger earnings, which decreased 1.2 per cent. Dividends at the rate of 8 per cent. per annum were paid during the year.

The gross earnings of the Toronto and York Radial Railway Company amounted to \$584,490, compared with \$492,922 for the previous year, an increase of 18.5 per cent.

CONSIDERATION OF ROADS IN TOWN PLANNING.

A road conference was held in London, England, late in December, which was called to consider the necessity in town planning schemes of co-operation between the various local authorities and the central authorities for the purpose of suitable and proper roads. Speaking on this subject, Mr. Burns said that there were signs in every direction that popular taste, executive desire, and administrative necessity were all tending toward a greater grasp of the road and town planning problem. Now that the town planning act was available for roads, as well as for town planning, they ought to utilize the general sentiment and, in each particular case, unite the central and local authorities, so as to secure the best results. This was already being done in England and Wales, as was proved by the fact that 200 local authorities were town planning, whilst in Greater London there were 80 local authorities of whom 38 were at work on different stages of town planning and road making. To further local co-operation in the carrying out of these schemes of town planning and road making, Mr. Burns proposed that first of all local conferences of the authorities of adjoining districts should be held at once. To these conferences should fall the duty of deciding the character, the varying methods, and, above all, the alignment of local roads, and the cost and its division among the various authorities interested. To these local authorities co-operating among themselves would be given help, guidance, advice and perhaps some money for individual schemes from the central authority.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

CONTENTS.

BOOK REVIEWS.

Elementary Graphic Statics.—By J. T. Wight, A.M.I.Mech.E., Lecturer in Machine Design, Heriot-Watt College, Edinburgh: published by Whittaker and Co., London, E.C. and New York, N.Y., 227 pp., 5 ins. x 7 ins.: cloth: 135 illustrations: price, $1 net.

This is a text book specially written for students in search of a working knowledge of the application of graphical methods to the solution of the simpler problems met with in engineering and building construction. The writer presents the subject clearly and in language readily understandable. The symbols used are those almost universally adopted. The illustrations are recognized as having been carefully and specially prepared in connection with the points under discussion, while the subject matter of each chapter is well supplemented by carefully selected examples to be worked by the student.

The book begins with a very elementary treatment of the graphic representation of forces, proceeding to their composition and resolution. Chapter 3, deals with simple, practical problems of the foregoing, such as loaded platforms, frames, tripods, cranes, etc. Moments, followed by bending moment and shearing force diagrams, precede an entrance into the investigation of loads and pressures on beams, roofs, girders, retaining walls, etc. Chapter 9, takes up the study of centre of gravity and moments of inertia.

It is a book not to be merely read, but to be carefully studied with continual reference to frame and stress diagrams contained therein, and the conscientious working of examples. Thereby students can readily acquire a competent knowledge of elementary graphical solutions.

Economics of Interurban Railways.—By Louis E. Fischer, Consulting Engineer, Missouri; published by McGraw-Hill Book Co., New York and London; 116 pp.; 5 ins. x 7½ ins.; cloth; price, $1.50 net.

The lack of data of actual and proven information so compiled as to be useful to communities where electric interurban railways are being promoted or contemplated, evidently prompted the writer to produce a resumé of the actual economic results which have been obtained from the operation of such railways existing in the United States.

The subject is treated in the following manner:—

Chapter 1, Inception and Development of Electric Traction; Chapter 2, Classifications and Definitions; Chapter 3, Operating Revenue; Chapter 4, Operating Expenses; Chapter 5, Cost of Construction; Chapter 6, Economic Relations of the Foregoing; Chapter 7, Conclusion; remarks based upon the statistics analysed. It brings out the fact that there are a great number of electric interurban railways now in operation that are not the commercial successes they are generally considered to be, due probably to an insufficient study of existing conditions and factors underlying success.

The author assumes the classification of operating revenues and expenses, etc., as prescribed by the Interstate Commerce Commission for electric interurban railroads; and from the operating records that are available, he selects indiscriminately a few cases, analysing them and making deductions respecting the relations of the various factors.

The book is well written and easily understood. A few ungrammatical expressions exist, for example, "there are such a variety of local conditions" is used on page 13. Again there are slight inaccuracies in numerical computations in one or two instances, but not of such a magnitude as to alter the potency of the conclusions drawn therefrom.

Those who are seeking to comprehend the fundamental conditions essential to an economically successful road, as well as investors trying to discriminate between fundamentally good or bad electric interurban railway securities, will find this book of great value and assistance.

Questions and Answers Relating to Modern Automobile Design, Construction Drawing and Repair.—By Victor W. Page, M.E.; published by the Norman W. Henley Publishing Co., New York City; 622+32 pages; 4¾ ins. x 7¼ ins.; cloth, price, $1.50.

As the title implies, the subject matter of this book is arranged in the form of lessons consisting of questions and answers. From very elementary topics the reader is brought progressively into the intricate study of features of design and construction. Every mechanical contrivance that has come into common use in automobile building seems to have been included. The numerous illustrations convey the impression that they are largely from the catalogues of prominent manufacturers, which the writer acknowledges at the outset.

Engineers who resort to the automobile in business or for pleasure will find this book worth many times its price for the suggestions it contains respecting the design, construction and repair of cars, equipment and accessories, as well as for the useful instructions respecting operation. The book is very carefully indexed and its diagrams are clear and not excessively reduced, many of them being in the form of inserts.

Cranes and Hoists.—By Hermann Wilda, translated from the German by Chas. Salter; publishers, Scott Greenwood and Son, London, E.C.; 158 pages; 399 illustrations; 4 ins. x 7 ins.; cloth; price, $1.

This book is a useful compilation on lifting tackle of all kinds. It is published in two chapters, the first being a study of the mechanics and theoretical design of chains, ropes, pulleys, hooks, brakes, bearings, couplings, etc., and the second being descriptive of the types of cranes and hoists ordinarily used. Although the book appears to be over-illustrated, and some of the illustrations are complicated owing to over-reduction, they are quite necessary, nevertheless, for a clear understanding of the text, the greater part of which is presented in a most condensed form, the trans-

lator apparently endeavoring to produce in a small [illegible] the information to which one often finds a book approximately twice the size devoted.

The calculations that are submitted may not be found of value unless a thorough study of the mathematics connected with each is made, and engineers in general might be disposed to consider the book as unbalanced both with regard to illustrations and mathematical computations. It is a subject nevertheless which demands a thorough treatment in the matter of design, and those who are interested in the construction of mechanical contrivances for the lifting and handling of all kinds of industrial machinery and apparatus will find the volume one remarkably concise and carefully translated.

Autogenous Welding, Oxy-Hydrogen and Oxy-Acetylene.—By R. Granjon and P. Rosenberg, translated from the French by D. Richardson, A.M.I.M.E., Lecturer on the subject at the Northern Polytechnic; published by Chas. Griffin and Co., Limited, Strand, London; 234 pp. + 12 pp. advt.; 257 illustrations; 6 ins. x 9 ins.; price, $1.25.

"Autogenous welding is certainly the one process of construction and repairs that requires, from top to bottom of its application most reflection, intelligence and conscientiousness."—Author's preface. This handbook on the use of oxy-hydrogen and oxy-acetylene blow pipes contains a great deal of practical information for the welder upon the scientific use of his apparatus and the most approved methods of operation. It presents a reliable, though simple, technique in the art of autogenous welding and is notable for the omission of intricate scientific considerations relevant only to a more advanced study of the subject. The fundamental principles serving as the base for all applications of the science are well brought out. The authors do not claim that it is in any way perfect or final as the science itself is only in its infancy. A very valuable feature of the book is its concluding chapter which deals with the cutting of iron and steel with the blow pipe and an oxygen jet.

The book will be warmly welcomed by engineers and manufacturers interested in the process, there being no other work on the subject in the English language at present.

PUBLICATIONS RECEIVED.

Cement Gypsum and Lime.—The 1914 directory of manufacturers. A 214-page leather-bound pocket directory, published by the Cement Era, Chicago, Ill.

Gas Analysis.—Errors due to assuming that the molecular volumes of all gases are alike. Issued by the United States Bureau of Mines, Washington. 16 pages.

Report of the Department of Public Works.—A 1913 report of the Minister of Public Works, Ottawa, including reports of Deputy Minister, Chief Engineer, Chief Architect, Accountant, etc.

Metal-Mine Accidents.—A booklet of statistics compiled by A. H. Fay for the United States Bureau of Mines, covering accidents of this nature which occurred in the United States during 1912.

Magnetite Occurrences Along the Ontario Central Railway.—By E. Lindeman, M.E., issued by Mines Branch, Department of Mines, Ottawa. 24 pages; illustrated by 9 photographs and 20 maps.

Clay and Shale Deposits of the Western Provinces.—Report by Heinrich Ries and Joseph Keele.; Geological Survey, Department of Mines, Ottawa. Memoir No. 25, 108 pages, fully illustrated.

Geology of the Coast and Islands Between the Strait of Georgia and Queen Charlotte Sound, B.C.—By J. Austen Bancroft. Issued by the Geological Survey as Memoir No. 23, Department of Mines, Ottawa. 150 pages; illustrated; additional maps.

Montreal Water Works.—By F. Clifford Smith. A 54-page illustrated booklet containing a historical description of the development of the Montreal water works system from the year 1800 to 1912.

Railway Statistics.—A report for year ending June 30th, 1913, of A. W. Campbell, Deputy Minister Department of Railways and Canals, Ottawa, compiled from returns furnished by the various railway companies of Canada.

Basins of Nelson and Churchill Rivers.—Memoir No. 30, Geological Survey, Department of Mines, Canada. Geological report by Wm. McInnes on the area west of Hudson Bay, embracing part of the Province of Saskatchewan and part of the Northwest territories.

Minutes of Proceedings of the 33rd annual convention of the American Waterworks Association, held at Minneapolis, Minn., June 23rd, 27th, 1913; 210 pp., 6 ins. x 9 ins.

Transcontinental Railway.—The 9th annual (1913) report of the National Transcontinental Commissioners setting forth the receipts and expenditures in connection with the eastern division and containing the reports of the Chief Engineer and District Engineers.

Variations in Results of Sieving with Standard Cement Sieves.—Technologic paper No. 9, of the United States Bureau of Standards, outlining the variations in determinations of fineness of cement that are liable to occur when the standard routine method of sieving is used.

Metallurgical Coke.—By A. W. Belden, United States Bureau of Mines. Containing statistics of coke production in the United States, development of methods, preparation of coal or coking, fiscal properties and chemical composition of coke, by-products, etc. 148 pages illustrated.

Topographical Surveys Branch.—Annual report of the Surveyor-General of Dominion lands for the year ending March 31st, 1912, containing reports of surveyors, maps, profiles and illustrations. The report contains, as appendix No. 51, an article descriptive of the copying camera of the Surveyor-General's office.

Austin Brook Iron Bearing District, New Brunswick.—A 16-page bulletin compiled by Einer Lindeman, M.E., for the Mines Branch, Department of Mines, Ottawa, covering the work done in, and the general characteristics of the iron-bearing district of Austin Brook, New Brunswick. Illustrated by charts and photographs, supplemented by maps.

Tests of Permissible Explosives.—By C. Hall and S. P. Howell, United States Bureau of Mines. A 310-page book with illustrations and tables describing apparatus and methods for physical tests of explosives and results. It contains a classification also of permissible explosives, their rates of detonation and useful suggestions in selecting explosives.

Coal Washing in Illinois.—Bulletin No. 69, Engineering Experiment Station, University of Illinois. A 108-page booklet by F. C. Lincoln, Assistant Professor of Mining Engineering, describing the purification of coal by mechanical treatment with water; containing sections devoted to history of coal washing, impurities in coal, crushing and sizing, methods of washing, arrangement and results.

Electrolysis in Concrete.—Technoligic Paper No. 18, United States Bureau of Standards, Washington. A 140-page treatise by E. B. Rosa, B. McCollum and O. S. Peters; containing investigations relating to the nature and cause of the phenomena resulting from the passage of electric currents through concrete; possibilities of trouble from electrolysis in concrete structures under practical conditions; protective measures, and conclusions.

Report of Transit Commissioners, City of Philadelphia.—A comprehensive report, dated July, 1913. Volume 1, of 267 pages, recommends a rapid transit system giving general

design, estimates, present and prospective traffic, time saved by rapid transit, estimate of income account, effect of rapid transit on assessed values, examples, with statistics, in other cities; population and housing statistics, etc. 120 pages of tabulated statements of construction costs, etc. Volume II. comprises 69 maps and diagrams, devoted to comparisons of transportation facilities in different cities, traffic, plans, time-distance, charts, etc. A Merrit Taylor, transit commissioner.

CATALOGUES RECEIVED.

Portable-Mine Hoist.—An 8-page bulletin of the Chicago Pneumatic Tool Company, descriptive of this type of air hoist.

Indoor Cable Terminals.—Bulletin issued by Standard Underground Cable Co., Hamilton, Ont. 32 pages, illustrated, including dimension charts, etc.

Single-Phase Induction Motors.—A description of type K.S., manufactured by the Canadian General Electric Co. Fully illustrated. Bulletin A-4185.

Arm Improvements.—A 16-page pamphlet published by the Canada Cement Co., and devoted to the use of cement and concrete for rural roads and buildings.

Electric Fans.—A descriptive catalogue of the 1914 types of fans offered by the Canadian Westinghouse Co., illustrated with photographs, dimension diagrams, etc.

Plymouth Products.—A 12-page bulletin issued by the Plymouth Cordage Co., Welland, Ont., descriptive of Manila rope and including an article on rope deterioration.

Locomotive Ratios.—An article by F. J. Cole, Chief Consulting Engineer, American Locomotive Co., New York, issued as bulletin No. 1017, illustrated with charts and tables.

Air Compressors.—An interesting publication by the Canadian Ingersoll-Rand Co., Limited, Montreal, describing their steam and belt-driven, single and two-stage, air compressors.

Lackawanna Steel Sheet Piling.—A 48-page booklet issued as bulletin No. 106 by the Lackawanna Steel Co., illustrating numerous incidents of its use in caisson and cofferdam work.

Power and Steam Pumps.—Catalogue No. 9 of the Smart-Turner Machine Co., Hamilton, Ont., describing numerous types of reciprocating and centrifugal pumps. 32 pages, illustrated.

The Reid Incinerator.—A 16-page illustrated pamphlet descriptive of some of the Canadian installations of the Reid hot blast tube incinerator and its method of destroying garbage and refuse.

Q.E.F. Runways.—Bulletin A-12, issued by the Herbert Morris Crane and Hoist Co., Limited, of Toronto, descriptive of some interesting recent illustrations of the Morris overhead runways.

Portable Meters.—Circulation No. 1104 of the Canadian Westinghouse Co., Limited, Hamilton, Ont., descriptive of the Westinghouse types [illegible] alternating currents.

Micaspar Crystals (Formerly Granite Crystals).—A 46-page catalogue of the Crown Point Spar Company, of New York, descriptive of structures in which these crystals have been used in the coating of cement surfaces.

Heating and Ventilating a Large Factory, and **Heat Transmission Through Building Walls of Corrugated Iron.**—Reprint of articles from the Iron Age and Engineering News respectively. Issued by the Green Fuel Economizer Co., of Mattewan, N.Y.

Direct Current Generators.—Circulation No. 1156, the Canadian Westinghouse Co., Limited, Hamilton, Ont. A 28-page bulletin giving illustrated descriptions of type "R" and type "S" D. C. generators, containing also a section devoted to field rheostats.

Catenary Line Material.—Catalogue D.S. 843 of the Westinghouse Electric and Manufacturing Co., descriptive of and illustrating different types of insulators, hangers, strain cars, etc., together with spacing diagrams for wheel and pantagraph trolleys.

Water Towers.—A 24-page catalogue descriptive of steel water towers, stand pipes, etc., of the Chicago Bridge and Iron Works, Chicago, Ill. Contains many illustrations of structures in Canada and the United States. Contains also tables of frictional losses, fire stream data, etc.

Iron Ore Washing Plants.—Bulletin No. 1807 of the mining machinery department of the Canadian Allis-Chalmers, Limited, Toronto. This 16-page booklet describes several installations and contains, besides photographs, a number of plans and elevation drawings showing ore washer arrangements.

Mill Type Motors.—This bulletin, issued by the Canadian General Electric Company, describes motors for service in steel mills, etc., where they are subjected to severity of operation. Various types of mill motors are described, for instance, with open and enclosed, D.C. and A.C. Bulletin includes dimensions, etc

Standard Reinforced Spiral Pipe.—A 36-page catalogue (No. 4), dealing with reinforced spiral pipe, forged steel flanges, valves, cast fittings and specialities used in connection with them. Fully illustrated. It contains complete price lists, and gives examples and uses. Issued by Standard Spiral Pipe Works, Chicago, Ill.

Alternating Current Motors.—A 24-page booklet issued by Bruce Peebles and Co., Limited, Edinburgh, Scotland. In two sections, the first dealing with open type polyphase induction motors, and the second with another form known as the self-contained type. The catalogue contains tables of dimensions, speeds, efficiencies, etc.

Sewer Failures.—A cleverly arranged and attractively printed booklet intended to show, by camera and laboratory, the relative advantages of various materials for sewer construction. Distributed by the Clay Products Publicity Bureau of Kansas City, Mo. "Sewer Facts" is the title of another interesting booklet published for the same purpose.

Alternating Current Signals.—A 52-page booklet issued by the General Railway Signal Co., Rochester, N.Y., descriptive of alternating current block signals on Southern Railway; written by W. J. Eck, Signal Electrical Engineer, Southern Railway Co. Well illustrated with photographs, diagrams of construction, details and wiring, interlocking, etc.

Excavators.—A well-illustrated 48 pp. pamphlet descriptive of the Shearer and Mayer Dragline Cableway Excavator. Numerous photographs are presented giving a clear conception of the uses of this class of excavating machinery in the mechanical handling of material under special conditions and difficulties. Issued by Sauerman Bros., Chicago, Ill.

Electric Mine Locomotives.—32 pages, devoted to an illustrated description of the Baldwin-Westinghouse type of electric mine locomotives and their equipment. Fully illustrated to show mechanical construction and performance of this locomotive, in the manufacture of which Baldwin Locomotive Works and the Canadian Westinghouse Co. are associated.

The Industrial Harbor.—A well-bound volume of 152 pages under the title of "The Industrial Harbor," is being distributed by Deutsche Maschinenfabrik, A.G., Duisburg, Germany, whose Canadian agents are Messrs. Gerald Lomer, Limited, Montreal. The book describes practically all the lifting and transporting appliances that might be required by any harbor for handling any sort of material whatever. It is abundantly illustrated with photographs of installations that have been used [illegible] the world

Coast to Coast

Agincourt, Ont.—The huge water tank at Agincourt in course of construction by the C.P.R., was destroyed by fire on February 19. The loss is estimated at $15,000.

Berlin, Ont.—Another new industry has been opened at Berlin. The Dominion Tire Company, owned and operated by the Consolidated Rubber Company of Montreal, has completed and formally opened its new $1,000,000 plant.

Elderbank, N.S.—Work on the Halifax and Eastern Railway in the Musquodoboit Valley is progressing steadily; and it is stated that by spring the grading that is to be done by the sub-contractors will be completed, also that by July, rails will have reached the Valley.

Clinton, Ont.—Clinton is now using hydro-electric power, connection having been completed about the middle of this month. The Niagara Falls power is not only to be used for light for streets and buildings, but also for the town waterworks system. Connection with the street lighting and manufacturing plants is not yet entirely completed.

Calgary, Alta.—For the year ending December 31, 1913, the gross earnings of the Calgary Power Company amounted to $240,116.28; operating expenses, $52,055.69; leaving net earnings available for bond interest, $188,060.59. After paying interest of $100,034.33 a balance of $88,026.26 remained, equivalent to over 4¾ per cent. on the common stock.

Regina, Sask.—The new reservoir to be built at Regina, and for which a site is now being secured, will hold a reserve water supply of 5,000,000 gallons, will be 26 feet in depth, and will be constructed of concrete. The site which is likely to be recommended by the commissioners will necessitate the laying of a 42-inch main between the tank and the power house.

Fort William, Ont.—The incinerator at Fort William has been set in operation, two of the three cells being kept busy steadily. The incinerator is reported as working satisfactorily, the consumption being about one wagon load every hour for each unit, or approximately 48 loads per day. The additional air blast supplied by the new fan has made a great difference in the heat generated; and the clinker which is now raked out from the front of the furnace is hard and well burnt.

Smithers, B.C.—Extensive deposits of iron ore of great value in the Copper River district, a few miles west of Smithers, have been reported upon by Mr. John V. Rittenhouse, of New York City, consulting and mining engineer. The ore deposits are situated between the town and Copper City and are the property of the North Pacific Iron Mines, Limited. The company's locations cover 375 acres, and it is the engineer's estimate that there are 10,000,000 tons of iron ore on the property, which is brown hematite in character. The deposit is similar to the Alabama deposits of bog iron, and analysis shows it to be well within the Bessemer limit.

Brantford, Ont.—The annual report of the Dominion Power and Transmission Company gave the following facts concerning Brantford:—"At the present time the company is connected with 2,124 motors of an aggregate capacity of 55,199 h.p. Additionally, the railway capacities require 6,250 k.w., or 8,333 h.p., and our lighting systems 13,132 k.w., or 17,500 h.p. During the past year the work of reconstructing the 22 miles of street railway tracks has been continued almost to completion, and considerable work has been done in the construction of 11 additional miles for the accommodation of the rapidly increasing population in the easterly section of the city.

Montreal, Que.—According to authoritative report from Montreal, C.P.R. extension plans of last year and this year will involve a total expenditure of about $85,000,000. At the present time there are 133 miles of double track under way between Sudbury and Port Arthur, on the Lake Superior division, which alone will cost $6,000,000; 178 miles of double track between Brandon and Calgary to cost $5,000,000; 139 miles between Revelstoke and Vancouver, to cost $7,000,000. Before the C.P.R. has concluded its present programme of work in the west, including the irrigation works, double tracking, and new trackage, amounting to 1,200 miles, it will have spent approximately $450,000,000 since its inception.

Ottawa, Ont.—An interim report has been presented to the Dominion Government at Ottawa upon the construction work on the N.T.R. during the nine months ending December 31, 1913. The total expenditure during that period is shown to be $10,314,944, which brings the total expenditure from the formation of the commission in 1904 to $140,562,147. The complete mileage is given as 2,231 miles; and it is stated that at the end of last year, the bridges were 95.3 per cent. complete. The report, moreover, asserts that at the end of last year, trains were being operated on 1,160 miles of the total 1,804 miles between Moncton and Winnipeg, and could have been run on the remaining mileage had there been any necessity therefor.

Regina, Sask.—The city commissioners have adopted for this and future years the policy of laying storm sewers previous to paving. Hence, all the streets included in this year's paving programme will be provided first with storm sewers. It is proposed also to construct two new storm water mains, one of 57-inch diameter and the other, 45 inches; while in these will terminate laterals ranging from 9 to 22 inches in diameter. New later sewers will also be constructed to connect with the present main which has its outlet into the creek at Campbell Street in the northern section of the city. The proposed new sewerage mains will serve the southern portion of Regina. The estimate for the work to be carried out this year upon the above constructions—e.g., 8 miles of mains and laterals—is given by the city engineer as $170,140.

Fort William, Ont.—The laying of the new intake main across the dam at Current River has been completed. The double force main, 450 feet in length, was connected on the ice just as if it had been laid on land and then placed in a wooden frame while 14 bents were driven at equal distances across the stream to support the pulleys by which the mains were to be lowered. The ice, 3 feet in thickness, was sawed to open a channel for the main, and then the whole length was slowly lowered to the bed of the river. No supports nor flexible joints were required to prevent the pipe breaking on the bottom as the bed of the river consists of hard pan. The trench for the mains was prepared in the summer and the river bed was found so firm that blasting had to be done to remove obstructions.

Victoria, B.C.—City Engineer Rust has reported upon the recommendation, recently made by the city officials, in connection with procuring a municipal paving plant. Mr. Rust considered the advantages and disadvantages of alternative locations at Spring Ridge and Garbally road yards, estimated the cost of each, and concluded in favor of the Spring Ridge site. He reported that a quotation had been submitted from F. D. Crummer and Son for a semi-portable plant with a capacity of 2,000 yards of 2-inch top per 10 hours, for $[illegible], that this with other necessary charges,

would bring the cost of the plant to $20,000; and that the Crummer plant could be made ready for operation within four months. Before the question of location or purchase is decided, tenders are to be called and considered for necessary equipment.

Winnipeg, Man.—A preliminary report was made at the annual meeting of the Winnipeg Electric Railway Company, held recently, upon the possibilities of power development at Big Bonnet Falls. It was shown that these falls were capable of producing 150,000 h.p. of electrical energy at a very low cost per horsepower. In view of the fact that the Winnipeg Electric Railway Company's water power plant at Lac du Bonnet with a capacity of 30,000 h.p. and its auxiliary steam plants in the city of Winnipeg, with a capacity of 18,000 h.p., are being utilized to their full extent, the necessity of immediate development of the new falls was apparent and it was decided to commence exploration and preliminary work immediately. It is expected that if energetic measures are taken and the matter pushed, power can be obtained from the new site within two years.

St. John, N.B.—Mr. A. D. Swan, M.Inst.C.E., has reported to the Board of Trade upon the progress and general conditions of the harbor works being undertaken at St. John. Alterations of importance suggested by the harbor engineer are a change in the direction of the extension of the Negrotown Point breakwater to Partridge Island; a spur extension from the other side of the island as an experiment to note the effect upon currents, and as a protection to both the new wharves on the west side of the harbor, and to the entrance channel leading to Courtenay Bay; and a change in the direction of the channel to Courtenay Bay. In closing his report, Mr. Swan comments upon the detached nature of the wharf accommodation; and he suggests that some scheme be devised, such as a bridge at the head of the harbor, so that all the various railway companies have some direct access to the new wharves.

Nanaimo, B.C.—Without any cessation in operations, the entire plant of the Nanaimo Electric Light and Power Company has been replaced. During the past year, the company has installed a directly connected unit of 450 h.p., manufactured by James Howden and Company, of Glasgow. The new engine is connected to a Bruce Peebles generator of 300 k.w. capacity, in addition to which the company has put in a new 6-panel switchboard which now gives it three separate circuits throughout the city, whereas prior to this installation but one circuit was in operation. The company has also installed a Stillwell heater and a Worthington feed pump; has laid five miles of new line and erected over 100 new poles in the city. It is the intention of the company this summer to install a line throughout West and South Nanaimo. This work will be supplemented by an addition to the plant.

Halifax, N.S.—The contract which has been recently awarded to Foley Brothers, Welch, Stewart and Fauquier, for the construction of the first unit of the new harbor terminals at Halifax, calls for the erection of a pier and a landing stage, which will be unique in their solidity and massiveness. The landing stage will be of concrete and 2,000 feet in length; the pier will be 1,200 feet in length; and there will be a basin 300 feet wide built inside of an extensive filling in from the land. This will give a lineal distance for shipping purposes of 6,200 feet. The work is to be solid throughout, not a structure resting on piles. The pier foundations will consist of 2,500 celular blocks, 20 feet by 30 feet, and each weighing 60 tons. These will be laid one on top of the other. Then the celular apertures will be filled with cement and rubble, allowing for expansion and uniting one block on top of another, and steel rails also serving to reinforce the structure. The floor will be laid in concrete; and the front of the entire 6,200 feet will be faced with granite blocks from low water to the floor of the pier and landing stage.

Toronto, Ont.—The official statement issued upon road construction under the Colonization Road Department during 1913, shows a distance covered of 1,300 miles, and an expenditure entailed of $406,351. Of the three road districts of the province, the northern district received 292 miles of colonization roads and 205 miles of by-law roads. In the western district, 110 miles of colonization roads and 80 by-law roads were built; while in the rest of the province (excepting Timiskaming, which constitutes a separate district), 292 miles of colonization roads and 344 miles of by-law roads were constructed. In the Timiskaming district, the work of the Colonization Road Branch was confined to the region south of Englehart, the northern part being under the supervision of the special roads commissioner, Mr. J. F. Whitson. In the part of Timiskaming covered, 85 miles of colonization roads and 113 miles of by-law roads were constructed. Finally, extensive work was carried out upon trunk roads, the Sudbury-Sault Ste. Marie road being almost completed. It is expected that this road will be ready for traffic this summer.

Victoria, B.C.—The plans for a retaining wall along the harbor front of the old Songhees Reserve, as prepared by Engineer Valiquette of the Department of Public Works for the Dominion Government, have been approved. It is estimated that the work will cost $147,773. A considerable quantity of rock and earth will have to be excavated outside of what will be the face of the wall. An immediate start on the erection of a creosoted pile wharf and the gradings of the actual site on the Songhees Reserve to the north of the proposed Johnson Street bridge will be made as soon as the contract is awarded for which tenders are being called by the Dominion Government. The plans show a wharf fronting on the channel 420 feet in length and running shorewards 224 feet, giving an approximate total of 650 feet of piling; and which, when completed, will be 5 feet above high water level. The total area to be excavated and levelled off is about 4 acres. It is understood that by the time the preliminary contract is completed, tenders will be called for the erection of the new Marine and Fisheries depot which is to be located at the Songhees Reserve facing south on the proposed bridge.

Winnipeg, Man.—Some interesting data has recently been published, showing the excellent result of an experiment started in Winnipeg nearly 15 years ago—e.g., its civic owned paving plant. When that city decided to purchase the first asphalt paving plant from the contractors and proceed with its own work, it at first experienced much difficulty in securing a full supply of material, owing to what was known as the "asphalt trust." However, in 1910, the city secured its first portable plant with which "No. 2" pavement is laid; and to-day, about 3,000 square yards of paving can be done each day. As the system is operated, the plant is in the position of a contracting firm financed by the city. The pavement is inspected as it would be were a contracting concern laying it. While the initial cost is somewhat higher, the results have proven excellent, especially when the question of repairs is concerned, this work being done more rapidly and the disputes relative to guarantee being eliminated. The average cost to the city per yard, on business streets, has been about $2.65; but on the business streets a pavement consists first of 3 inches of gravel ballast, then 6 inches of concrete base, 1½ inches of binder course and 3 inches of asphalt wearing surface. Broken stone drains every 50 feet are also included in the cost. The city advertises every job as open to competition, the engineer putting in a bid; but the strictness of the specifications are such that contractors claim they cannot compete with the city.

NEWS OF THE ENGINEERING SOCIETIES

Brief items relating to the activities of associations for men in engineering and closely allied practice.
THE CANADIAN ENGINEER publishes, on page 94 a directory of such societies and their chief officials.

ONTARIO LAND SURVEYORS' ASSOCIATION.

Annual Meeting Held in Toronto, February 17th, 18th and 19th, 1914.

The morning session on the 17th was devoted to meetings of standing and special committees and meeting of the council of management.

In the afternoon, the president, Mr. J. S. Dobie, delivered his address, which was a resumé of the past year's history on matters of interest to the association. It contained many useful suggestions for the future, all of which were heartily endorsed by the meeting.

Reports of council of management, board of examiners, secretary-treasurer, committees on legislation and on publication, were presented and dealt with.

Mr. H. T. Routly of Toronto, presented his paper on "Contour Survey on Abitibi River," which evoked considerable interest. The contents of the paper were made clear and described by means of a large copy of the plan of survey.

Mr. H. O. Dempster of Gananoque, Ont., gave an interesting description of survey work in British Columbia, the different systems of survey and the conditions under which these are made.

Mr. E. W. Neelands of New Liskeard, Ont., had a paper on water power development and the transmission of electric power in Northern Ontario.

8 p.m.—Professor L. B. Stewart, of the Faculty of Applied Science, Toronto University, presented a very interesting paper on the Inter-provincial Boundary between Ontario and Manitoba, describing the different astronomical problems and the calculations involved in the question, as well as the method of procedure in defining the line on the ground.

Mr. J. F. Whitson, entertained the convention for some time with lantern slide pictures of the work of road building and colonization in Northern Ontario, and also many pictures of natural scenery in the northern and western parts of Ontario.

Wednesday Session.—Mr. C. J. Murphy, Toronto, chairman of the committee on land surveying, presented his report including answers to the question drawer, which involved the solution of many intricate points regarding the legal method of procedure in certain surveys.

Mr. T. B. Speight, Toronto, read a paper on "Surveys in Certain Townships in the 640 acre Sectional System," and some of the difficulties to be worked out where the original survey was lacking in accuracy.

Mr. A. G. Ardagh, Barrie, read a paper on difficulties arising from surveys made in double front concession townships, and pointed out several cases where the procedure under the Survey Act was not definite.

In the afternoon, Mr. G. A. McCubbin, St. Thomas, chairman of committee on drainage, presented the report which outlined improvements necessary for the good of the public and the benefit of drainage engineers.

Mr. Alan M. Jackson, Brantford, read a paper on "Permanent Street Grades," which was heartily endorsed. He advocated the fixing of permanent levels in new subdivisions in order that a builder might rely on having a fixed level of street before constructing buildings on the adjoining lots.

Mr. E. D. Bolton of Listowel, presented a valuable paper on the "Working of the Ditches and Watercourse Act," describing the difficulties arising in proceeding and carrying out drainage under this Statute.

Banquet.—The annual dinner of the asociation was held on Wednesday evening, at the Engineer's Club, and was one of the most successful dinners in the history of the association. The guests included Hon. W. H. Hearst, E. Douglas Armour, Frank Arnoldi, R. F. Stupart, F. C. Mechin, J. S. Bach, E. J. Zavitz.

Responses to the different toasts were both eloquent and humorous, and the evening was enlivened with songs by Messrs. Boyd, Phillips, LeMay, Leigh and Bartram.

On Thursday morning the association concluded its meeting by pasing resolutions, vote of thanks to all those who helped to make the convention a success. Matters of new business and unfinished business were attended to and the election of officers. The following were elected:—

President, J. W. Fitzgerald, Peterborough; vice-president, E. T. Wilkie, Toronto; secretary-treasurer, L. V. Rorke (re-elected), Toronto; council of management (2 to be elected by letter ballot), J. M. Watson, Orillia; E. D. Bolton, Listowel; Jno. H. Shaw, North Bay; G. B. Kirkpatrick, Toronto; J. J. McKay, Hamilton; auditors, Jno. VanNostramd, Toronto; A. E. Jupp, Toronto.

The meeting of the association is held on the second Tuesday in February each year in Toronto.

TORONTO BRANCH, CAN. SOC. C.E.

Toronto branch of the Canadian Society held a very important and well-attended meeting, Wednesday, February 25th, in the Chemistry and Mining Building, University of Toronto. Mr. C. N. Monsarrat, C.E., chairman and Chief Engineer of the Quebec Bridge Commission was the speaker. He gave an illustrated address on the foundation work in connection with the construction of the new Quebec bridge. The paper was most interesting, and brought forth some very complimentary discussion.

The following meetings for the Toronto branch are announced:—

Thursday, March 5th—Discussion on the "New Specifications for Reinforced Concrete."

Thursday, March 12th—Luncheon.

Thursday, March 26th—Address on "The Proposed Terminal of the T. and N.O. Railway System on James Bay," by J. G. G. Kerry, C.E.

Thursday, April 16th—Luncheon.

Thursday, April 23rd—Paper on "The Clays and Clay Industries of Canada," by J. Keele, B.A.Sc., of the Geological Survey of Canada.

The luncheons will be held at 1 p.m., and the evening meetings at 8 p.m.

Members will be notified by mail as to the place of meeting.

VANCOUVER BRANCH, CAN. SOC. C.E.

At the meeting of the Vancouver branch of the Canadian Society of Civil Engineers on February 18th, there was a discussion of the proposed Second Narrows dam and the Pitt River Canal. The discussion brought out a variety of opinions, as to the desirability, cost and effects of the proposed works.

Mr. J. H. Kilmer, engineer of Coquitlam, opened the discussion, being familiar with both the projects and having at different times studied plans and specifications for the dam as well as much data dealing with the canal, having himself made one report on the latter. The canal, he said, was an historic enterprise, having first been broached by Col. Moody, over 40 years ago. The scheme was again resurrected some 20 years ago by Mr. David Oppenheimer and associates, a company was organized for the undertaking and full surveys made with complete details of construction. These unfortunately had been lost but sufficient data remained on which to base conclusions.

The canal could be constructed either with locks at either end or with the placing of a dam at the Second Narrows which would obviate the necessity of a lock at Port Moody. The completion of either or both would make available large areas suitable for industrial sites with rail and water shipping facilities.

Others took part in the discussion including Messrs. Cartwright, Cameron, Webster, Creer and Matheson. In references to the canal, excessive cost in relation to the benefits were spoken of, and also the danger of it filling up from silt from the Fraser. Cost, too, was a feature in the dam construction with added difficulty from the depth of water over a hundred feet in mid channel, and the debris swept down by the mountain torrent which the Seymour Creek becomes at times.

Its effect on the lower inlet was also regarded as an important feature. Opinion differed as to the effect the dam would have on the tides, but the preponderance of ideas seemed to favor the theory that the dam would lessen the scour of the outgoing tide through the First Narrows and consequently increase impediments to the channel there.

PAPER ON SUBSTRUCTURES.

On Thursday evening, 19th inst., John W. Doty, A.M.Can.Soc.C.E., M.Am.Soc.C.E., of the Foundation Company, New York, read a paper at a meeting of the general section in Montreal of the Canadian Society of Civil Engineers. The subject was "Building Structures, Built by the Pneumatic Method."

ENGINEERING SOCIETY—UNIVERSITY OF MANITOBA.

At its regular meeting on the 9th inst., papers were read by Messrs. J. R. McColl and F. V. Woodman, members of the society. The latter spoke on "Elevator Construction at Fort William" and the former on "Construction of the Canadian Pacific Railway Red River Bridge." Both speakers are members of the second year in engineering, University of Manitoba.

ORGANIZATION IN ROAD BUILDING.

The Sanitary and Highway Club of the University of Toronto, a club of fourth year men in these two courses in the Faculty of Applied Science and Engineering, were addressed at their semi-monthly meeting on the 21st inst., by W. A. McLean, C.E., Provincial Roadway Engineer and a member of the Ontario Public Roads and Highways Commission. Mr. McLean spoke on the essentials of organization in road building, outlining the duties of the various members of a road staff. Some time was taken up in discussion after the lecture. Mr. J. A. P. Marshall is president of the club.

THE DEFINITION OF "CIVIL ENGINEER."

A deputation representing the civil engineers of British Columbia waited on the provincial executive council a few weeks ago with a protest against that clause in the Municipal Act which practically gives the municipalities of the province the right of interpretation of the term "civil engineer."

They suggested that the definition of civil engineer should be one who is a member of the Canadian Society of Civil Engineers or of the sister organization in Great Britain, or some society for which the qualifications for admission to membership were recognized by these two parent societies. The Premier promised that the matter would receive the consideration of the executive council.

COMING MEETINGS.

CANADIAN MINING INSTITUTE.—Sixteenth Annual Meeting to be held at Windsor Hotel, Montreal, March 4th, 5th and 6th, 1914. Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

AMERICAN WATERWORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Deven, 47 Slate Street, Troy, N.Y.

CANADIAN AND INTERNATIONAL GOOD ROADS CONGRESS.—To be held in Montreal, May 18th to 23rd, 1914. Mr. G. A. McNamee, 909 New Birks Building, Montreal, General Secretary.

PERSONAL.

H. G. HUNTER, resident engineer for Canada of the New York Continental Jewel Filtration Co., has been elected to full membership in the Canadian Society of Civil Engineers.

ANGUS McDONNELL, who has recently gone into large contracting work on the Pacific Coast has, according to announcements, secured from the Dominion Government the contract for the harbor works at Victoria, B.C.

J. C. DUFRESNE, M.Can.Soc.C.E., M.Can. Mining Institute, at present field engineer for Cummins and Agnew, Vernon, B.C., has resigned from the latter firm and is re-establishing his private practice at Penticton, B.C.

P. B. YATES. of Toronto, has been appointed engineer and manager of the Hydro-Electric Power System of St. Catharines, duties to commence on March 15th. Mr. Yates has been connected with the Hydro-Electric Power Commission of Ontario for the past five years, previous to which he was in the employ of the Gould Storage Battery, Chicago.

ARTHUR H. BLANCHARD, M.Am.Soc.C.E., Professor in Charge of the Graduate Course in Highway Engineering at Columbia University, on February 14, 1914, delivered illustrated lectures at the University of West Virginia on the subjects:—"Park Boulevards," "Bituminous Surfaces and Bituminous Pavements," "Wood Block and Stone Block Pavements" and "Modern Developments in Highway Engineering in Europe."

GEO. D. MACKIE, formerly city engineer of Swift Current, Sask., has secured the long-deferred appointment of City Engineer of Moose Jaw, Sask. Some 40 applications were received last fall and the work of selection has been slowly, but carefully, proceeded with. Mr. Mackie has had some 13 years' experience in municipal work. He was with the John Galt Engineering Co., at Winnipeg and Calgary before taking office at Swift Current. A greater part of his municipal training [illegible] in [illegible] and Clydebank

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

21351—February 12—Extending, until the 15th day of May, 1914, the time within which to complete the spur for the Renfrew White Granite Co., Limited, township of Ross, Ont.

21352—February 9—Ordering the C.P.R. to appoint a permanent agent at Millett Station, Alta.

21353—February 12—Extending, until the 21st May, 1914, the time within which to construct switching lead in the city of Toronto, Ont.

21354—February 12—Approving revision in the location of a portion of the C.P.R. Co.'s Columbia and Western Line at mileage 0.45, Granby Subdivision, through Lot No. 1494, Group 1, and Lot No. 332, Group 1 (Provincial Government Survey, District of Yale, B.C.).

21355—February 12—Authorizing the G.T.P. to carry traffic on the said portion of its main line of railway east of Prince Rupert, B.C., between mileage 301 and mileage 337.

21356—February 12—Approving, temporarily, G.T.P. Standard Freight Mileage Tariff, C.R.C. No. 21, incorporating and superseding C.R.C. No. 19, by an extension of the mileage thereof, to apply between stations in the Province of British Columbia, between Prince Rupert and Wordsworth, inclusive.

21357—February 9—Granting leave to the Hydro-Electric Power Commission of Ontario to erect, place and maintain its line across the wires and across the track of the C.P.R. on Main St., Chesterville, Ont.

21358—February 13—Approving Plan "A," showing G.T.R. bridge No. 63, mileage 152.51 from Black Rock, over public road at Golmesville, Twp. Goderich, Ont.

21359—February 14—Authorizing G.T.R. to reconstruct bridge No. 52, at mileage 127.75 from Black Rock, on the 20th District of its line of railway, Twp. Fullarton, Ont.

21360—February 13—Authorizing the C.P.R. to construct a highway diversion in the S.E. ¼ of Sec. 26, Twp. 3, Rge 29, W. 3 M., Sask.; and to construct, by means of a grade crossing, the tracks of its Weyburn-Stirling Branch Line across the highway between Secs. 25 and 26, Twp. 3, Rge. 29, W. 3 M.

21361—February 14—Authorizing the C.P.R. to construct highway diversion in Sec. 1, Twp. 23, Rge. 2, W. 4 M., Alta.; and to construct, by means of a grade crossing, the tracks of its Bassano Easterly Branch Line across said diversion at mileage 111.3.

21362—February 14—Authorizing C.P.R. to construct highway diversion in Sec. 9, Twp. 23, Rge. 1, W. 4 M., Alta.; and to construct, by means of a grade crossing, the tracks of its Bassano Easterly Branch Line across said Diversion at mileage 114.7 on said Branch line.

21363—February 13—Authorizing C.N.Q. Ry. to construct, maintain and operate siding into sand pit at mileage 16.90, west of Joliette, for E. Dupuis, St. Julienne, Co. Montcalm, Que.; and to cross with such siding the said public road to Bissonnette, at Station 66.70.

21364—February 13—Authorizing the C.P.R. to construct, at grade, the tracks of its Swift Current Northwesterly Branch Line, at mileage 169.89, across the tracks of the C.N.R. Co.'s Goose Lake Branch at Mileage 210.12, in Sec. 29, Twp. 28, Rge. 5, W. 4 M., upon certain conditions.

21365—February 13—Authorizing the Township of McKim to construct and maintain a highway crossing over the Algoma Eastern Ry. in Lot 11, Con. 4, Twp. of McKim.

21366—February 14—Authorizing the C.P.R. to construct, maintain and operate branch line of railway, or siding, for the Conger Lehigh Coal Co., Limited, Toronto, Ont., on subdivision Lots 12, 13, 14, 15, 16, 17, 18, 19 and 20, lying northerly of Vine St., Toronto, Ont.

21367—February 17—Amending Order No. 21172, dated January 7th, 1914, by striking out word "Broadview" in third last line of recital to said Order, and substituting word "Brandon."

21368—February 17—Authorizing Kettle Valley Ry. to carry traffic over portion of railway from Penticton Wharf, in westerly direction, a distance of 17 miles, B.C. And that portion extending northerly and northwesterly from Carmi to mileage 76.5, Prov. B.C., a distance of 30 miles.

21369—February 16—Rescinding Order of Railway Committee of Privy Council of Canada, dated Sept. 1st, 1899.

21370—February 17—Authorizing C.P.R. to construct spur for Henry Hope & Sons, of Canada, Ltd., in Park Lot 4, Tp. Lot No. 13, Con. 12, formerly Tp. of Monaghan, now City of Peterborough, Ont., subject to certain conditions, and rescinding Order No. 21232, dated Jan. 19th, 1914.

21371—February 17—Directing that C.N.R. reconstruct its station building at Aberdeen, Sask., work to be completed by first day of July, 1914.

21372—February 17—Authorizing C.P.R. to construct road diversion in Sec. 26-21-5, W. 4 M., Alta., at mileage 88.9 of Bassano Easterly Branch Line.

21373—February 17—Authorizing C.P.R. to construct diversions of East and West road allowance in Sec. 2-22, and Sec. 34-21-7, W. 4 M., Alta.; and construct, by grade crossing, Bassano Easterly Branch Line across North and South road allowance between Secs. 2 and 3, Tp. 22 and Secs. 34 and 35, Tp. 21, Rge. 7, W. 4 M.

21374—February 17—Authorizing C.P.R. to construct highway diversion, as revised, in Sec. 20-21-8, W. 4 M., Alta., and to construct Bassano Easterly Branch, by means of grade crossing, across said diversion at mileage 66.39.

21375—February 17—Granting leave to C.P.R. to carry party of mining students of McGill University at special rate of $40.00 per capita for trip from Montreal, Que., to Rossland, Phœnix, and Greenwood, B.C., and return, or at $50.00 per capita from Montreal to Vancouver, B.C., and return, including side trips to Rossland, Phœnix and Greenwood, B.C. 2. Granting leave to carry such party, if desired, over lines from Sudbury to Sault Ste. Marie and back at rate of $2.75. And that any other parties desiring to travel for same purpose to British Columbia or any other mining district, be granted equally favorable terms, until otherwise ordered by Board.

21376—February 19—Authorizing C.P.R. to construct Bridge No. 62.8 over Magnetawan River, near Byng Inlet, Ontario.

21377—February 18—Authorizing C.P.R. to use and operate Bridges Nos. 25.7, Laggan Sub. Div., Alta.; 92.3, Boundary Sub. Div., B.C., Div., B.C., and 176.9, Calgary Sub. Div., Alberta Div., Alberta.

21378—February 18—Making Montreal Warehousing Co. a party to application of Montreal Board of Trade for an Order directing G.T.R. to put into effect at its Montreal Elevator the same charges and conditions for elevation, storage, and loading of grain into cars as are in force at its elevators at Georgian Bay ports.

21379—February 19—Authorizing G.T.P. Branch Lines Co. to construct road diversion in S.W. ¼ Sec. 24-1-3, W. 2 M., Sask., at mileage 151.5 on Regina-Boundary Branch.

21380—February 19—Amending Order No. 21161, dated Jan. 7th, 1914, by striking out words, "and G.T.R. Co., as set out in letter of McCarthy, Osler, Hoskin & Harcourt to Chrysler & Bethune, dated Jan. 6th, 1913," in 3rd, 4th, 5th lines of recital to Order, and by adding at end of said recital words, "and the G.T.R. Co. of Canada, under a reservation of its rights, if any, as a riparian proprietor, not objecting."

21381—February 19—Amending Order No. 21139, dated December 31st, 1913, by striking out word "Saskatchewan," where it occurs in said Order, and substituting word "Alberta."

21382—December 12—Authorizing C.N.R. to construct across nine (9) highways on its Alsask Southeasterly Line in Saskatchewan.

HIGHWAYS AND HIGHWAY SURVEYING

FURTHER POINTS ESSENTIAL TO A SCIENTIFIC APPLICATION OF SURVEYING PRACTICE TO HIGHWAY WORK—SUGGESTIONS PERTAINING TO LEVELLING

By **DANIEL J. HAUER**
Consulting Engineer and Construction Economist

[*Note—This article on levelling in connection with highway surveying follows directly the subject matter of another which appeared in February 19th issue under a similar heading. The plotting and some other features of highway surveying will be dealt with in a later article.—Editor.*]

The Work of Levelling.—The taking of levels over the surveyed area is of great importance and should be done with care and judgment. If possible, a bench mark established above tide water should be obtained to start the levels. This can frequently be done from some railroad company or government survey. If this is not possible, and the surveys start near tidewater, a gauge should be put on the beach, and mean tide or mean low water obtained. The value of this is evident. On extensive surveys all sections of the work can be checked if the levels are on the same datum line. These levels can also be used for any work, and it is always of value to have them based on tide water. However, if it is not possible to get such an elevation to start the levels, an assumed elevation can be used, taking care that it is large enough to prevent any minus elevations.

With a bench mark to start from, the first work to do is to run a set of benches over a part of the surveyed line. This is one difference between highway surveying and railroad surveys. On highways the line of the survey is known, while on railroads it is not. Thus benches can be run ahead of the transit party. With a set of benches run, they can be checked as the line levels are taken, thus the levels are checked as they are taken. It is customary to run the levels as the benches are established, afterwards checking the benches. By this method, if errors are discovered, either a long line of levels must be run over or else two elevations from a bench mark must be used, one in each direction from the error, which is a great inconvenience and may lead to other mistakes.

If the benches are run first and then checked the levels can be kept right, it seldom being necessary to run over more than 1,000 ft. By all means, no matter how they are run, have the levels and bench marks checked. This is the only proper method and will save much confusion later, as well as time and money.

Levels should check within a few hundredths between benches and within a tenth for a mile. If they do not, they should be re-run until they do. Bench marks should be established about every 500 ft., making about 10 per mile. In very level country they can be farther apart, but even then not more than 1,000 ft. It is very little trouble to make benches, and to have them close together means the saving of much work on locations and construction. They should always be established near cross roads and bridges. If the bridge is high there should be one at the road level and one near the stream, so that work can be done from one set up on any part of the structure. If the bridge is a long one, a bench should be on each side, and these should be checked within one hundredth of a foot.

Bench marks can be made on the knots of trees. These are most permanent and can be used for some years. Door steps and curb stones in towns and villages can likewise be used. When trees or stones are not convenient, heavy spikes can be driven into telephone or telegraph poles along the road. Any heavy spike will do if it is driven securely, leaving only enough of the head projecting to the bear level rod. A railroad spike gives the best bench mark of this kind.

Many poles have to be removed to allow of road improvements, so it is often necessary to transfer bench marks from one pole to another. Other expeditious ways of making bench marks will suggest themselves. If the work is extensive enough and the cost will warrant it, permanent stone or concrete monuments can be set for some of the bench marks. These should have a copper tack or plate set in them, and if of concrete the elevation should be cast in the concrete.

If possible, all bench marks should have their elevations marked on them. A description of each should be entered in the note book with its location described in reference to the transit line. A list of bench marks, their elevations and description should be entered in the back of each level note book for quick reference.

In taking levels, each station should be taken on the transit line and at each break in the ground. When the transit line is not the same as the centre line of the road the centre must also be taken. These two elevations are most important. In addition to them the elevation on the sides of the roads should be taken. If the ground dips or rises much beyond the sides of the roads, enough elevations should be taken to show the character of the ground to about the limit of the right-of-way of the road. From such notes it is possible to plot cross-sections of the road.

It is evident that with the large number of levels to be taken and with checking the bench marks, the work of levelling on highway surveys goes much slower than the work of running the transit line. Thus every help

possible should be rendered the leveller and his rodman. Plus stations marked on poles, fences, stakes, culverts and bridges will all aid in making measurements. If the road does not vary much in elevation from one side to the other and if the ground on the sides is about the same, it is evident that quicker progress can be made by only taking side levels every 200 instead of 100 ft. Other opportunities of saving time will present themselves to the leveller. The successful levelman is he who is so watchful that he does not waste time by taking useless notes and at the same time makes his notes so complete that a profile can be made of the transit line, of the centre line and of each side of the wagon road; and any cross-section that will show decided cutting and filling in widening the road.

work, both in recording the notes and in plotting them. This is to place all the rod readings in one column and the elevations in another, and on the opposite page show by notations the places where these levels were taken. This is shown by a sample page, Fig. 1.

The second method is similar to keeping cross-section notes. The rod reading for the transit line and its corresponding elevation is recorded, as usual, in the columns on the left-hand page and the rest of the readings on the right-hand page, as shown in Fig. 2. It is possible to set down the elevation directly instead of the rod readings, by doing some extra work in the field. Thus, above the break shown on the page, the top figures are rod readings and the bottom figures distances out from the transit line. The letter "C" denotes the centre

Fig. 1.—Ordinary Level Book, With Notes.

At cross roads levels should be run down the centre of the roads for such distances as to show the grade of these roads and how they may be affected by changes to be made. This may mean 100 ft. or more. On private roads and entrances to farm houses, levels should be taken for at least 100 ft. or to the houses. At culverts and bridges, in addition to levels taken in the road, the elevation of the banks of the stream, the surface and bottom of the water should be ascertained, and any other elevations that may affect the building of a new bridge or culvert.

The Levellers' Note Book.—The keeping of level notes is not a difficult problem, but unfortunately the manufacturers of note books have not kept abreast of the times, there being no special book for highway surveys. The one in common use is well adapted to railroads, but is poorly suited to highways as it causes much extra

of the wagon road. The figures written vertically are the elevations of the points alongside of them.

Below the break in the page (Fig. 2) the top figures are the elevations and the bottom figures, distances out. In this the rod reading is not recorded except for the reading on the transit line. Thus, at Station O (zero) the rod reading is 6.2 on the transit line, the instrument height being 67.5; the elevation as recorded is 61.3. Now, keeping the rod 6.2 on a piece of paper, as the mean rod for that cross-section, the reading at the centre of the road, being 6.2, gives an elevation of 61.3, which is set down on the right-hand page as 2 ft. on the right and at centre. The reading at the edge of the road, 8 ft. out, is 6.4, being 2 tenths lower than the transit, making an elevation of 61.1, which is so recorded. At 12 ft. out the rod reads on top of the side of the cut 4.1, making a difference of 2.1 with the mean rod, thus adding 2.1 to

the elevation on the transit line, making 63.4. The same is done on the left, and at each station the operation is repeated. The notes are thus made complete in the field and a large number of levels can be taken and recorded on a section. Although some time is saved in the long run, yet in cold weather it is difficult to do this in the field, and the chance of errors being made is considerable.

Fig. 3 shows a method of keeping level notes that is less work than that shown in Fig. 1, is very accurate, and can be used by a leveller of limited experience. A cross-section book for plotting contours can be used and ruled up in any manner desired. For standard use the writer uses the ruling shown in Fig. 3. The columns for rod readings are made narrower than for elevations for two reasons, as so much space is not needed, and the recorder can find them more easily. The figures in circles with the rod reading tell the distance out to the right or left of the transit line. With this method the notations necessary in Fig. 1 are eliminated by the columns and the elevations except for the turning points, bench marks, and instrument heights, can be marked up in the office. The writer is a firm believer in keeping the elevations mentioned marked up in the field, and checking them each night by addition and subtraction.

It is evident that plotting the notes shown in Fig. 3 any line or profile can be plotted with little trouble. The elevations of the transit line, the centre line of the road, the sides, etc, are all in single columns, except where the transit line coincides with the centre of the road only the elevation of the transit line is shown.

Each night, or on stormy days, all elevations should be marked up and the notes plotted.

COMMERCIAL RED LEAD FOR PAINTING STRUCTURAL STEEL.

By A. Gordon Spencer,

Chief Chemist, Canadian Inspection and Testing Laboratories, Limited, Montreal.

RED lead is one of the best-known and most widely used pigments at the present time for painting steel for structural and railway purposes, but very few of the consumers seem to realize the great difference in quality of the red leads sold by the manufacturers and jobbers, nor the effect of the ingredients upon the quality and durability of the paint in service.

Red lead as sold on the market is mainly a mixture of two oxides of lead, true red lead and litharge. It is made by roasting, or oxidizing, pure metallic lead in reverberatory furnaces in two stages. In the first stage the lead is melted down on the flat hearth of the reverberatory while a strong current of air is passing across its surface. Litharge, or the monoxide of lead, is formed under these conditions as a skin or crust upon the surface of the molten metal and is pushed to the back of the furnace, continually exposing fresh metallic lead to the oxidizing action of the air. Finally, all the lead becomes changed into brown-colored scales of litharge, which on grinding produce the reddish-yellow litharge of commerce. The second stage in the process consists in the further oxidation of the ground litharge in the same or a similar reverberatory furnace to true red lead. The temperature and other conditions have to be carefully controlled or, otherwise, the bright red color will be spoiled and the quality of the pigment impaired. If the oxidation is not carried far enough considerable litharge will still remain and the color will be pale. If carried too far the red lead becomes more dense and crystalline, and hence is more difficult to mix with oil into a paint and is liable to run or streak. If the temperature becomes too high, the red lead is decomposed to litharge again and a partial fusion of the material will result. The final product should contain no grains of metallic lead nor fused particles, but after grinding very fine should be of a brilliant red color and with only a small quantity of litharge.

The chemical composition of true red lead is considered to be a compound of two parts of lead monoxide and one part of lead dioxide, but the commercial product always contains litharge in varying proportions as the analyses given in Table I. will show.

Red lead containing a large percentage of litharge when mixed with oil sets into a cement in a comparatively short time. This makes it difficult to work and uneven in application. A pure red lead, on the other hand, is more inactive to oil and brushes out more smoothly. This allows the painter to cover more surface with the same quantity of paint with less exertion and in a shorter time, so that the increased cost of a high-grade red lead is more than repaid by the economy in application, as well as in the increased beauty and durability of the paint; not to mention the better protection of the steel work obtained. Fineness of grinding is, of course, an essential characteristic, as otherwise even a high-grade red lead would run and alligator.

In view of the wide variation in the purity and quality of the commercial article now on the market it would, therefore, seem advisable where large contracts are concerned and where durability and uniformity of the painting is necessary, to buy it under specifications and to rigidly inspect and test all shipments received. The following might be suggested as a specification for this purpose:—

Specification for Dry Red Lead.—The dry pigment must be of the best quality, free from all adulterants, and shall contain not less than 85 per cent. by weight of true red lead (Pb_3O_4), the balance to be practically pure lead monoxide (PbO). It must contain less than 0.1 per cent. of metallic lead, and is to be of such fineness that not more than 0.75 per cent. remains after washing with water through a No. 19 silk bolting-cloth sieve. It must be of good, bright color, and be equal to the standard sample in freedom from vitrified particles and in other respects.

Samples of one ounce of the dry red lead must be submitted to the..............Company's Chemist for analysis for each new order for the materials. No material shall be shipped until the above sample has been approved by the Chemist. Shipments must be uniformly in accordance with the specification. Further samples may be taken at any time after delivery, and if the material is found not to be in accordance with the specifications, all the materials represented by such samples shall be rejected.

Standard samples of dry red lead will be furnished on application to the..............Company's Chemist.

Wherever possible it should be arranged to have the shipments of red lead sampled before shipment, so that all trouble, delay and possible disputes may be avoided by reason of the shipment being rejected after delivery had been made. The buyer, or his representative, could then get an unbiased average sample of the different barrels of material, seal them with his own private stamp, taking note at the same time of the numbers and marks of the barrels. If the analysis proved satisfactory the latter could then be checked up and identified upon delivery. In this way no further delay nor trouble should result and both buyer and seller would be equally satisfied.

* Percentage.

SOME FEATURES IN THE DESIGN OF SEWER SYSTEMS.

THE design of a sanitary sewer system for a town having a combined system serving approximately 2/3 of its area and 9/10 of its population and the subsequent construction of parts of the system and of some storm sewers is the subject of a paper read recently before the Association of Civil Engineers of Cornell University and appearing in the February number of The Cornell Civil Engineer. Mr. C. F. Fisher, of the Fairport (N.Y.) Sewerage System, is the author.

In the particular case which Mr. Fisher selected the existing sewers had been built without regard to any particular outfall, and the problem was that of combining them into a system which should serve the entire community and deliver the sewage at some outfall convenient for the treatment of the sewage.

Before proceeding to the actual design of a sewer system, the factors of future growth of the town, the character and quantity of its sewage, the conditions of its present sewers and the local topography must be considered. In estimating future growth not only the corporate area should be included, but the areas which are liable to be developed during the period it is assumed to care for. The railway facilities will usually indicate in what direction new industrial works may be expected to grow up, but the development of residential districts does not admit of such accurate forecasts. In the smaller cities and towns the main highways which are susceptible to improvement as state roads are the more likely avenues of development.

The character of the sewage will govern somewhat in the selection of the minimum grades to be used. Where manufacturing wastes of a fibrous or a gritty character occur it will be necessary to provide for a higher velocity of flow, preferably not less than three feet per second, than where domestic sewage only is expected. This requirement becomes more important where the discharge is periodic in sewers maintaining only a small normal flow. A dilute sewage admits of a lighter grade than a heavy one, and more especially so if its diluteness is due to the infiltration of ground water in old sewers, since that fact insures a steadier flow. In a separate system the problem of street grit can be eliminated by the use of tight manhole covers, or, if perforated covers are necessary to provide ventilation, by the use of dustpans in manholes.

In estimating the amount of sewage per capita per day to be expected recourse will be had to the records of water consumption for the community in question. These records, if pumping records, or records made at the intake of the water system, will show a consumption which will be in excess of the flow of sewage by the amount of leakage in the waterworks lines. However, other facts concerning the water supply may be large factors in the expected sewage flow. At Fairport, N.Y., the water consumption from pump records for the winter months, when sprinkling, etc., was zero, was 65 gallons per capita per day. This water is obtained from shallow wells in shale and is highly mineralized. In consequence, the use of cisterns to catch roof water is universal. No records were available showing what the actual per capita consumption of this roof water was, and in the absence of any definite data, an allowance of twenty gallons per capita per day was made, as being sufficient to cover general domestic uses. The cisterns in which this water is collected drain into the sewers, which will form a part of the sanitary sewer system, and, during heavy rains, all the overflow from the cisterns will pass through the sanitary sewers. The amount of this overflow is difficult of estimation. A computation of the amount to be expected by means of roof area and rainfall data, assuming that only 10 per cent. of the cisterns would overflow at once, gave an amount of water manifestly too large to provide for in sanitary sewers. It was not possible in this case to observe the increase in flow due to rains because a great many surface laterals were connected to the sewers and contributed to their flow. It was advisable to make some allowance for this water because of the limited extent of the storm water system and the probability that it would not be extended to cover the town for some time. The total amount of sewage proper to be expected was determined as 80 gallons per capita per day and the maximum flow on the maximum day as 170 gallons. An allowance of 100 gallons was made for cistern overflow in addition to the sewage flow. This amount seems liberal, and the sewers were not designed to carry this amount flowing half full but practically three-quarters full. In case future experience should show this amount to be too small an allowance for cistern overflow, the remedy will lie in connecting the overflow to the storm sewers, whose construction should be assured before the main trunk sanitary sewers carry the flow from the full estimated population for which they were designed.

The condition of the existing sewers is sometimes hard to determine, especially where no maps have been filed or manholes built along the line. The grade of many of them is an indeterminate thing as they have frequently laid over an uneven bottom. The fact that they are discharging sewage is presumptive evidence that they are in fair condition. However, when it is designed to lay pavements over them, it is necessary to dig up the sewer at several critical points before assuming its efficiency, and manholes should then be built along the line.

The proper layout of the system to take advantage of the local topography, can only be finally determined by making actual estimates of cost of the best of the apparent locations. The inclusion of the old sewers complicates the problem as they were frequently built in short sections at a time, following the growth of population, and do not take advantage of the steepest grades available. Theoretically, the most economical type of layout is that in which the main trunk sewers follow the steepest grades, since the smaller laterals seldom carry their full capacity, even on light grades.

Before proceeding to the layout of any comprehensive sewer system it will be economical to make a good topographic map of the area to be sewered and any probable extensions to that area. Such a map should include all probable sites for disposal plants and all areas contributing surface drainage. A scale of 100 feet to the inch shows detail enough for fairly smooth country where the slopes do not exceed 10 per cent., but in rough topography and in locations which a preliminary examination shows to be likely routes for intercepting sewers a scale of 50 feet to the inch is preferable. A contour interval of 2.5 has been found satisfactory in smooth country, and ten feet is close enough for long, steep slopes. It is advisable to write in the actual elevation at street intersections and abrupt changes of slope. The amount of detail it is advisable to show on these maps depends somewhat on the probable time of construction. If the investigation is only preliminary in character and actual construction is liable to be long deferred it is useless to take a large amount of detail, which may change materially before actual construction. But where it is expected to build shortly, it is a matter of economy to locate the houses and all structures, even if they do not actively govern the location of the sewer. From these large scale maps a map of a smaller scale, 200 or 300 feet to the inch, can be prepared as an index map, or for

filing purposes. It is helpful also, where the topography is complex, to have a small scale map to bring out the general features of the country more prominently than is possible with several separate maps. In transferring topography to the small scale map it is essential to transfer the street lines and main drainage lines and divides with a fair degree of accuracy. The absolute correctness of intermediate points is not so essential since final locations and estimates will be made from the large scale maps. These maps will be of great value in future municipal work if they are filed in the city offices so as to be available.

The method of preparation of these maps will depend largely on the tastes and previous experience of the engineer in charge of surveys. It is possible to make fairly good maps by the method of transit topography and a draftsman to plot the transitman's notes, but the cheapest and most accurate method is by plane table surveys. By this method there is so much less detail left to the draftsman's imagination. It is necessary to use the transit and level to secure adequate control for plane table surveys, and distances, such as length of streets, should be chained unless accurate maps showing such lengths are available. In open country a transit survey to locate control points not less than 1,000 feet apart should be made and level bench marks established every 1,000 feet in distance and at least every 20 feet in elevation. With the control points plotted on plane table sheets about 20" by 30" and a party consisting of topographer, recorder and rodman, maps can be made which will be superior in their general accuracy to maps made by the transit method, and will be almost as cheap.

In these maps all existing sewers should be located and their exact elevations determined, even if it is necessary to dig them up to do so. Attention needs to be given to the grades of water and gas mains parallel to the new sewers, since they may interfere with the house laterals.

Before proceeding to lay out a system on these maps it is necessary to consider whether a storm sewer must be built in the near future in streets now served by existing combined sewers, if no storm sewer is to be built the old sewer will be used if possible as a part of the new system. If a storm sewer needs to be built, the question arises whether the existing sewer is of sufficient capacity to serve as a storm sewer for the area. The fact that it has so served is not evidence that it will continue to do so under new conditions incident to prospective street improvements, etc. In this case, in order to obtain the best design, it becomes necessary to practically lay out a storm sewer system for the town. It will usually be found that the old sewers are too small to be used for storm sewers. In a case in mind in only one instance was the old sewer of sufficient capacity to provide proper drainage. Here the old sewer was used for a storm sewer and a new sanitary sewer built. Questions of the efficiency of the existing sewers as sanitary sewers also affect the design. It is possible that they are entirely too large to be self-cleansing when the drainage of the street no longer enters to periodically flush them. This fact, combined with the infiltration of ground water, may be serious enough to warrant the construction of a new sanitary sewer. Unless the street is to be immediately improved, or the use of the old sewer makes a considerable detour in the direct route of the new construction necessary, however, it will be best to use the old sewer for a sanitary sewer if its grade permits. In case it develops into an active nuisance a new sewer to take its place can always be laid later.

A further point deserving of more consideration than it usually receives, especially in small communities, is the securing of proper ventilation of the sewers. The common method in large cities is by the use of ventilating ducts through the houses to the roof. In small communities it will be found, however, that a large proportion of the houses have house-traps, which prevent the circulation of air through the sewers and ventilating ducts. In such cases it is necessary to secure the passage of an ordinance prohibiting house-traps or ventilate the sewer through perforated manhole heads. It is usually easy to secure the passage of the ordinance, but where the town does not have a plumbing inspector it is a difficult matter to enforce it. The enforcement of such an ordinance is, however, so essential to prevent nuisances from foul-smelling manholes that every effort should be made to secure competent inspection of the installation of house fixtures.

For sewers of small sizes the use of vitrified clay or tile pipe is universal. Vitrified pipe, however, is so subject to breakage, due to the unyielding character of the material and the imperfect bedding of the pipe usually secured, that more attention should be given to the prevention of breakage than is commonly done. It is a common practice to place a concrete or timber foundation under sewers where the bottom is soft. The restriction of this foundation to soft bottom indicates an intention to provide against settlement rather than against breakage. In this connection it is interesting to note a discussion of the strength of sewer pipe by Dean A. Marston and A. O. Anderson, of Iowa State College, in which they conclude from their observations that (1) it is impossible to prevent cracking of the larger sizes (over 15") of pipe by precaution as to bedding and laying the pipe or refilling the ditch; (2) that pipe cracks more readily on hard, unyielding bottom than on soft bottom; (3) that it is necessary to require the contractor to carefully shape the bottom of the ditch to conform to the surface of the under half of the pipe; (4) and to carefully bed the pipe in sand or granular material; (5) that sewer pipe cracks from such slight distortions as compared with the yielding of the most solidly packed earth filling that it is not possible to prevent cracking by side-tamping at the mid-height; and (6) that when the above precautions do not prevent failure it is necessary to bed the pipe in concrete up to its mid-height or else use stronger pipe. These conclusions are not verbatim as given in the Record, nor do they comprise all of their conclusions, but they state the gist of their conclusions as to prevention of failure by care in laying pipe.

Their statement that pipe cracks more readily on hard bottom than on soft is illuminating when regard is had to the practice of placing concrete foundations on soft foundations only. Their conclusion (3) as here enumerated is practically impossible in hard and stony soils, and is almost never done in any soil. In any soil such a requirement entails an amount and quality of inspection rarely given to pipe sewer construction. Conclusion (4) seems more possible of attainment, but would require that the trench be excavated larger and deeper than the outside of the pipe and the granular material placed and tamped around and under the pipe. Their conclusion that "sewer pipe cracks from such slight distortions as compared with the yielding of the most solidly packed earth filling that it is not possible to prevent cracking by tamping the ditch filling on each side of the pipe at mid-height," indicates the equal impossibility of preventing cracking by excavating the bottom of the ditch to a cylinder true to the line and grade of the outside of the pipe. An attempt to secure this condition will result in leaving narrow cavities under the pipe too small to be tamped full of earth, and "slight distortions" of the pipe will be very apt to occur.

It appears that the statement "that when failure occurs in spite of the careful observance of the other precautions, the only effective remedy is to bed the pipe in concrete or use stronger pipe" indicates the advisability of laying all large pipe in concrete or else using double strength pipe. In the absence of experimental data as to which of these alternations is the stronger construction, the concrete is to be preferred, since it lends itself to the making of tighter joints, particularly where cement joints are used or in wet trenches. All sewer pipe up to, and including 12" diameter, commonly conforms to the accepted specifications for double strength pipe.

Concrete for this purpose need not be expensive. During November and December of 1913, 47 cu. yds. of a 1-5 hand-mixed gravel concrete was laid under about equal lengths of 15" and 20" pipe for an actual cost, including excavation for same, of $4.00 per cu. yd. Here the gravel cost $1.07 per yd. and cement $1.50 per barrel, delivered. Labor was 20 cents per hour. Very little foreman's time was included in the cost, since the work required practically no additional supervision. This cost does not include the removal of the excess material from the street, since in this case the earth was sold for the cost of removal. This figure would need to be increased in deep trenches where the cost of excavation was high or where the concrete could not be shovelled directly in place.

This sewer formed part of a storm sewer, the main outfall of which was 27" in diameter. On the outfall the cut was so shallow that it was feared a tile sewer would be broken under the weight of heavy rollers which it was expected to operate over the street preparatory to laying a pavement. Part of the sewer passing under railway tracks also required a stronger construction than tile. A concrete sewer 27" inside diam., 6" walls, with six ⅜" square bars placed longitudinally and spaced equidistant in the walls, was used as giving a stronger section. The structure was built of 1:4 gravel concrete and the interior was painted with grout. Some criticisms of this section were made by bidders as being too small to build economically of concrete. The cost as tabulated below indicate that the concrete sewer was built considerably cheaper than a single strength tile sewer laid on concrete could have been. The entire section of the sewer was run at one pouring, leaving no joints except at the end of each day's run.

Cost of 27" Concrete Sewer.

Item.		Amount.	Unit Cost.
	Labor.		
Laborers, Exc. and backfill,	677½ hours @ 20c.	$ 135.50	0.472 per cu. yd
Laborers, concreting.	510 " @ 20c.	102.00	1.46
Foreman, exc. and backfill,	58½ " @ 40c.	23.40	0.081
Foreman, concreting,	40 " @ 40c.	19.40	0.28
	Total	$280.30	$ 0.72 per ft
	Materials.		
Gravel,	70 cu. yd. @ $1.07	74.90	
Cement,	105 bbls. @ 1.50	157.50	
Forms,		64.85	
Miscellaneous supplies,		13.00	
	Total	$310.25	$ 0.82 per ft
	Total Labor and Material		1.52 per ft.

Results of hydrographic surveys conducted throughout the summer under the auspices of the naval service department, lead to the conclusion that first-class harbor facilities are to be found in James Bay in the vicinity of the mouth of the Nottaway River. Good shelter, ample room and a sufficient depth of water have been found and very little silt is in evidence to necessitate dredging. Soundings indicate plenty of water right out into the bay.

THE FUNCTIONS OF THE ENGINEERING SOCIETY.*

By L. K. Sherman,

President, Illinois Society of Engineers and Surveyors.

THE constitution of almost all engineering societies state that "the objects of the organization are the exchange of technical knowledge and experience and the advancement of the engineering profession." The benefits derived from the presentation of papers and the exchange of professional experience are of themselves ample reason for membership in the society, and incidentally they are large factors toward the professional advancement of engineering.

In my opinion, however, the time is now ripe when the engineering societies should enlarge their field of endeavor from the purely technical and literary functions to engage directly in efforts promoting the material status of the engineering profession and the individual members thereof.

I am not advocating this effort to promote the material status of engineers because of any alarming conditions. Engineering has advanced from a trade to a profession. Figures gathered by engineering societies, records of the graduates of technical schools and pay rolls of corporations show that the average annual income of the civil engineer to-day compares moderately well with similar statistics of the lawyer and doctor.

The field of the engineer has broadened, especially in lines of sanitation, highway construction and reclamation of lands. His position before the public is better recognized. Engineers are being placed as town managers, on public commissions, as investigators for financial corporations, and as constructors, instead of letting the work by contract.

It is, however, not our place merely to accept what the conditions of the times offer; it is our duty to take advantage of and to push those conditions which result in our rightful material welfare. This can be accomplished only through organization. This is the day of organization—individual effort fails. In business, consolidations alone survive. If engineers are to progress and to retain their rightful sphere they must do so through organization. The legal and medical professions are strongly organized to guard and advance their interests in legislation and in public relations. The architects of this State have an able organization, which legislated a certain kind of structural work out of our hands into theirs. Almost all lines of business have their lobbies. However much we may disagree with the methods of the building trades union we have to admire the efficiency of such organization. Some factors that have contributed toward the delinquency of engineers furthering their material welfare are their modesty, the fact that they are migratory animals, their false sense of dignity and too much conservatism. One of the unavoidable handicaps of the civil engineer arises from the very nature of his work. His work ends when the particular structure which he may be engaged on is completed. He then must seek other and often remote fields where new construction is to be started. These intervals between jobs are often of frequent occurrence. Thus the engineer is a migratory animal. I do not mean to underrate the desirability of maintaining the dignity of engineering as a profession, but dignity should not interfere

*Presidential address to the annual meeting of the society.

with business progress with us any more than it does with law or medicine.

I once heard of a secretary of an engineering society who was so conservative that he did not believe in any co-operation with the societies and in fact scarcely believed in a meeting of his own society.

The Illinois Society of Engineers and Surveyors has been one of the few engineering associations to enter the field of promoting material professional welfare. This society originated a movement to demand justice for a member engaged on a government bureau at Washington. Our action and his vindication were highly commended by the technical press, but the conservative constitutions of many engineering societies preclude this sort of work. During the past year a proposition was submitted at Springfield to place the State Geological Survey under the Board of the State University. This matter was brought to our attention and after consideration by the trustees and officers of this society it was decided that the proposed change would be detrimental to the efficiency of the Geological Survey, and communications were sent to a number of legislators at Springfield to that effect. The change was not made and the Survey maintains its separate existence.

After the passage of the law creating a State Public Utilities Commission, this society presented a petition to the Governor urging the appointment of an engineer upon said commission. Our membership is now honored with a member of the State Public Utilities Commission. In a number of instances the society has had special committees working in the interests of legislation affecting surveys and matters pertaining to land drainage and special assessment work.

The technical press of the country during the past year contains more communications than in any previous period on: "The Status of the Engineer"; "Compensation of Engineers"; "Engineers' License Laws"; "Code of Professional Ethics"; and "The Consolidation of the Engineer's Work in Large Engineering Corporations," etc. An association of consulting engineers in New York has been actually formed to handle these matters. The formation in Chicago of a Technical League, a union of engineers, associated with the American Federation of Labor, is a recent and most radical development. All of this is an indication that the engineering society is not entirely meeting the problems of material professional welfare.

Among the plans, projects and suggestions presented for advancing the status of engineers are: The licensing of engineers and surveyors; civil service laws; legal compensation for city engineers, etc.; trade unions; code of professional ethics; standardization of fees; and employment bureaus operated by the societies.

I cannot attempt here to consider the various arguments for and against these plans. What I am advocating here is that it is the proper duty and function of the engineering society to consider such plans, and to have an organization which possesses the necessary executive machinery to act upon those measures which are of benefit, and to circumvent those which are detrimental to the engineer and his allied works.

I recommend that the trustees and officers of this society be authorized to act as an executive committee in the name of the society in all matters of legislation and public relationship, and to receive, consider and act upon, or report upon, any complaint or suggestion presented by any member of the society. I also advocate the appointment of a committee on legislation whose duties it is to follow and to report to the executive committee any proposed state or municipal legislation which might be of interest.

The local or state engineering society is the logical organization to initiate such measures as are conducive to the material betterment of engineers. The efforts initiated by the local society should in turn be supported by the action of the interstate or national engineering societies.

The ability to accomplish practical results will to a large extent depend upon the numerical strength of the society. The voice of the society should be the representative voice of all engineers in the state. I believe that if the state society would acquire the reputation for action in measures affecting the status of the engineering profession and especially of its individual members there would be an immediate and large addition to its membership list.

POWER DEVELOPMENT AT GREAT FALLS, MAN.

Mr. Gano Dunn, president of the J. G. White Engineering Corporation of New York, was in Ottawa recently conferring with the Dominion Water Power Branch regarding the development of water power at Great Falls, on the Winnipeg River, in the province of Manitoba. This company has been retained by the Winnipeg River Power Company to design and construct a 100,000 horse-power plant at Great Falls. It is desired to have construction work commenced as soon as possible after the spring break-up, and an initial installation of 40,000 horse-power completed for use within three years.

The engineers of the Dominion Water Power Branch have recently completed an elaborate investigation of the Winnipeg River powers, and general conclusions have been arrived at with respect to the best method of concentrating the several natural falls of the river in order that there may be no portion of it left unused. As the Great Falls development must form a component part of the comprehensive scheme of concentrations arrived at by the Water Power Branch engineers, the J. G. White Company have made a thorough study of the Government investigations, and have decided to recommend to their clients, the Winnipeg River Power Company, that the Great Falls development should conform to, and be a component part of the Government proposals. Engineers of both the Water Power Branch and the company are in conference at Winnipeg and Ottawa in connection with the whole project with a view to having the necessary plans, specifications, etc., required by the Dominion regulations, submitted to the Department of the Interior for approval at the earliest possible date, in order that construction work may be commenced early.

The hearty approval by the J. G. White Corporation of the conclusions arrived at by the engineers of the Dominion Water Power Branch is a well-deserved tribute to the good work done by them in connection with important power possibilities of the Winnipeg River. This work has attracted a great deal of favorable attention, and the complete report of the investigations which will be published in the coming summer is awaited with great interest by all those interested in power development in Canada.

It is stated that the Western Railway of Buenos Ayres will eliminate all existing grade crossings and will electrify its suburban zone for a distance of about 25 miles from the terminal.

METHOD OF WELDING JOINTS IN CONTINUOUS STEEL GAS AND WATER MAINS AND OIL PIPE LINES.

THE material most commonly used for jointing water and gas mains is lead. For cast iron pipes, except where turned and bored joints are used, lead still holds the field undisputed excepting by a few patented lead compounds. Since the introduction of steel pipes with bell and spigot joints, lead has also been used for jointing steel pipes.

Since the perfection of oxy-acetylene welding, several attempts have been made to weld steel pipes together into continuous mains. Probably the most successful experiments of this sort have been those conducted by Stewarts and Lloyds, Limited, of England. This firm has patented a method of welding steel pipe joints that seems to have passed the experimental stage and to have become a commercial success.

Their joint consists of a spigot with a slight taper, which is drawn tightly into a faucet with a corresponding taper (see Fig. 5), the welding being effected by fusing soft Swedish charcoal iron wire with the metal of the spigot and faucet by the oxy-acetylene process. The close fit of the tapered surfaces of the spigot and faucet relieves the actual weld of any bending stresses which may come on the pipes.

Fig. 1.—Welder working underneath the joint.

The end of the faucet is slightly bellmouthed, and this bellmouth serves the threefold purpose of facilitating the entry of the spigot into the faucet, of affording a long contact surface for the weld, and of enabling the joint to be safely and easily made from either above or below the pipe without endangering the person of the welder.

Fig. 3.—Welder at work in position where it has been impossible to turn pipe so as to keep welding portion at the top. A recess was made to allow the welder sufficient space to work all around the joint.

The welding outfit consists of a supply of compressed oxygen, usually confined in steel cylinders holding 100 cubic feet, and an acetylene generator and gas holder, fitted with a purifier. To the oxygen cylinders are attached a reducing valve and two pressure recorders, one for recording the pressure in the cylinder, the other for recording the pressure at the outlet of the reducing valve. The carbide for making the acetylene is supplied in air-tight drums containing 100 lbs.

The acetylene generator, gas-holder and purifier and the oxygen cylinders are mounted on a small trolley which can be wheeled from joint to joint along the trench as the welding progresses.

In districts where few cross-pieces are encountered in the trenches it is usually most convenient, in dealing with pipes up to 6 in. and 8 in. internal diameter, to weld the joints above ground over a couple of trestles or timber triangles (see Fig. 4), one about 18 in. and the other

Fig. 2.—Stretch of pipe being lowered into trench after pipe has been welded above ground.

Fig. 4.—Six-inch pipe welded on trestles, then settling by its own weight into trench.

about 36 in. high, shifting the trestles forward a pipe length at a time, as each weld is completed, and allowing the finished part of the pipe line to settle down into the trench by its own weight, the pipes and joints being strong enough to make this method practicable.

Where the pipes must be threaded into position among numerous cross pipes, electric conduits, etc., the above method is impracticable. Under such circumstances some or all of the joints must be made in the trenches, without turning the pipes round, and to do this a recess about 6 feet long and 12 inches to 15 inches deep, under and in line with the pipe, must be provided at each joint for the welder, as shown in Fig. 3.

Where the trenches are straight and free from bracings it is practicable to weld up 6 to 12 pipes, depending on the diameter and conditions, either above ground (see Fig. 2) or in the trenches, without having a recess at every joint for the welder, the pipes being turned round as the welding of the joints proceeds. Two or more stretches having been welded up in this manner, these stretches can be welded together in the trenches, recesses for the welder being necessary, of course, at such welds, as shown in Fig. 1.

Joints occasionally occur in awkward positions, amid a labyrinth of other pipes. Welded joints in such positions may offer considerable difficulties, but the same applies to lead joints, the main difference being that to make a lead joint it is not always necessary to see it, but it is necessary to have sufficient space for the free use of the caulking tools and hammer. With welded joints, on the other hand, such clearance is often unnecessary, provided the welder can see the joint all round the pipe.

After welding, the joints can be tested with water or compressed air (see Fig. 6) before being put into service. In short lengths of main, or mains of small diameter, this can be done by means of a hand-operated pump, but where this would be too slow, a power-driven compressor can be employed.

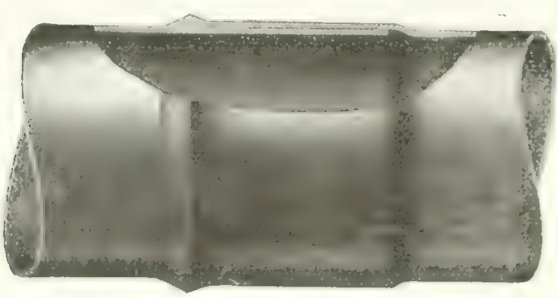

Fig. 5.—Welded socket and spigot joint.

When a main is being laid, the work is not delayed by the welding, as the welder, with his burner and rubber tubes, his gas outfit, a few bottles of oxygen and a small quantity of iron wire, will weld up at the rate of 150 feet of 4-inch main per hour, the pipe being in 20-foot lengths.

The cost of the joint under favorable conditions is said to be about the same as that of lead joints.

One of the objections commonly raised against welding long lengths of pipe into a continuous piece is that expansion and contraction due to variations in temperature may damage the joints.

In this connection interesting experiments were conducted by the patentees. A long straight pipe, held longitudinally and transversely against deformation, will be stressed to the extent of 2,240 lbs. per square inch of pipe section for every 10° F. variation in temperature. Tests of the patented joints showed a tensile strength of over 20 gross tons per square inch of pipe section. Under actual tests, variations of 80° F. did not affect the joints.

Fig. 6.—Testing main with compressed air to thirty pounds per square inch. Part of trench has been filled in, leaving only joints exposed.

A continuous stretch of these welded pipes, 4 inches internal diameter and 350 feet long, was embedded in a trench between two heavy concrete blocks and subjected to an air pressure of 100 lbs. per square inch, both ends being sealed. Throughout its entire length the temperature of this pipe was varied from day to day over a range of 80° F. for a month, the pipe ends meantime being kept rigid by the concrete abutments. At the end of the month the joints were as tight and sound as when first made.

Regarding the permanence of the joint under vibration, two 20-foot lengths, welded together and set horizontally, were vibrated by means of an eccentric with a 6-inch lift, revolving 300 to 400 times per hour, day and night, for a period of three weeks. After this severe treatment the joint was tested and was found sound and tight at 100 lbs. pressure.

When welding round the joint and coming back to the starting point, a small portion of the first weld is remelted to secure continuity in the weld. If this is not done a leak may develop at that point.

Steel pipes are coated outside and inside, or outside only, as required. The usual practice is to wrap the pipes, after the outside coating has been applied, in jute cloth saturated with solution. But, to avoid discomfort to the welder, the pipes are left free of coating and cloth for a distance of about 6 inches from each end, and a sufficient quantity of special solution for applying cold and hessian cloth for wrapping the joints after welding,

is supplied with each installation. The mains are thus not only welded up into one continuous length, but they are also provided with a continuous coating of anti-corrosive material, reinforced by a continuous envelope of cloth soaked in the same rust-resisting compound.

Steel pipes with this type of joint have been supplied for gas and water mains, and also for oil pipe lines, laid under water. In the latter case the pipes were paid out like a cable from a barge as the joints were made, and in a certain instance were welded on the bank and drawn in one length across a river a mile wide.

They have also been used for pump delivery mains in vertical pit shafts, the welding being done in the shaft, and in some cases on the pit head; the main, in the latter cases, being let down, a pipe at a time, as each joint was completed. The tensile stress on the joint, due to the weight of a vertical line of pipes 1,000 feet long, is equivalent to about 1½ gross tons per square inch of pipe section. As the joints have been found by tests to bear fifteen times this stress, the patentees state that this method of jointing may safely be adopted even for very deep shafts.

THE RELATION OF RAINFALL TO RUN-OFF IN AMERICAN RIVERS.

In a paper, published recently in the School of Mines Quarterly of Columbia University, Mr. W. F. White, Jr., assembles the available data on the rainfall and run-off in the various drainage basins of the United States, in an endeavor to determine what definite relations there exists between them. The following extract from his paper brings out also the factors that influence these relations, with their nature and relative importance:

The subject is one to which little study has been devoted, and the scarcity of written information is surprising considering the importance of the questions involved, in the development of both water power and water supply. The subject, furthermore, has a vital bearing upon the floods, which are of frequent and disastrous occurrence in some sections of the country. In the Am. Soc. C.E. Transactions are several papers with lengthy discussions which afford much valuable information on the actions of several individual streams and of the proportion of run-off from their catchment basins. The United States Geological Survey has taken up the study of rain and run-off, and in one of its bulletins G. W. Rafter sums up what is known of their relations. In addition, several water supply papers on various areas have given figures for the per cent. of rainfall appearing in stream flow, but have not gone more deeply into the causes of the variations for different times and streams.

Sir John Murray has published an article (Scottish Geographical Magazine, Vol. 3) on the amount of rainfall and run-off of the large rivers of the globe, and from them has assumed the ratio of run-off to rainfall for the world. He estimates that ratio is as 1 to 4.499, or about 22.2 per cent. of the precipitation. An interesting paper, "Ecoulement fluvial et Denudation," by H. Baulig, bearing more on the problems of denudation by streams, and on the chemical side, has recently appeared; with this, the list of papers on the relations of rainfall and run-off in the United States practically ends.

For the calculation of the ratios in this paper, the measurements have been taken for the years 1906 to 1910 inclusive. In this 5-year period a very good average of weather conditions is obtained, especially in regard to the precipitation. Of the five, two were of rather greater rainfall than is the ordinary experience, viz., 1907 and 1909; two were of less than average rainfall, namely, 1908 and 1910; and one, 1906, was of nearly average amount. These statements can be made, however, only in a general way, and the mistake must not arise of assuming that any one section of the country had precipitation of more than average amount, because the country as a whole had a year of heavy rainfall. Thus, though the year 1907 had generally a much heavier rainfall than 1908, yet locally, as in the southeastern states, the latter year records the heavier precipitation. This goes to show that the rainfall is a very uncertain quantity, and makes difficult the task of determining the amount at one point of comparison with that of some other region.

The amount of rainfall even in one place shows surprising variation from year to year. In general, the maximum annual total is from two to four times the minimum. Thus, at Orono, Me., a record for 42 years gives a minimum annual precipitation of 28.5 in. in 1895, and a maximum of 58.7 in. in 1888, or a ratio of 1 to 2.1. At Boston a record for 74 years shows extremes of 27.2 in. and 67.7 in., or a ratio of 1 to 2.5, slightly greater than at Orono. The mean annual rainfall for the whole United States amounts to 29.4 in., but, due to the extreme variability for different places and times, gives no clue to the rainfall of any particular area.

The distribution of the rainfall through the year also varies greatly in different sections of the country. The precipitation may be fairly uniform throughout the year, as in the New England states, where the mean of a period of years showed that 12.2 in. of rain fell in spring, 11.4 in. fell in summer, 11.7 in. fell in autumn, and 11.7 in. fell in winter. On the other hand, the precipitation may be nearly all crowded into one period, as is commonly the case along the Pacific Coast, where, in the Sacramento Valley, 83 per cent. of the annual precipitation falls in the period from November to April.

When rain falls on the surface of the earth it may do one of four things: It may be evaporated directly by the sun; it may flow directly into streams or lakes; it may sink into the ground; or it may be taken up by vegetation or combine with minerals of the earth's crust. The part that is evaporated by the sun is lost, and no further consideration of it need be made. The quantity of water which finds its way directly to streams varies greatly with the time of year and the nature of the country. It is much higher in winter, when the ground is frozen, than in summer, when the rain has a chance to sink into the ground. This part constitutes what is known as surface flow.

That part which sinks into the ground is by far the greatest and most important, though it, too, varies with the nature of the soil. In a sandy, porous soil the amount will be very high, while in an impervious, clay soil it will be comparatively slight. This underground water serves as a source of supply in times of drought. It may reach the surface in springs, wells, or by seepage. This last is of the greatest importance, and, when it is considerable, serves to keep the flow of the streams uniform throughout the year. When it comes to the surface it is again exposed to evaporation and is partly removed in that way. With the exception of a negligible amount which sinks into the earth and is not recovered, this water finally is returned either as stream flow or evaporation.

Of the part that is consumed by vegetation, some is lost, but a considerable proportion is returned to the atmosphere by evaporation from leaves and other surfaces. Thus a very large part, which has been estimated

at over 99%, is ultimately delivered back in the form of stream flow and evaporation. It is with stream discharge, or the run-off from a catchment basin, that we have specially to deal. The amount of this depends primarily on the precipitation, for without this there could be no run-off; yet there are many other factors which influence the flow, and create very complex relations.

The flow of streams has been divided into the following periods: Storage, growing, and replenishing. The storage period for the eastern United States begins about December, though it may vary from year to year and in different localities, and concludes about May. During much of this time, evaporation is slight and the demands of vegetation are small, so that a large percentage of the rainfall reaches the streams. The growing period includes approximately the months from June to August, during which time both absorption by plant life and evaporation are at a maximum. As a result, the amount of rainfall that finds its way to the streams is small, and the streams have their minimum flow unless a very rainy season upsets the customary conditions. During this period, the drain on the underground water supply is severe and the level of the ground water falls. During the replenishing period, which lasts from September to November, the flow assumes more normal conditions, and the run-off is higher than during the growing period. The ground water regains its former height, and by the beginning of the next storage period everything is in favorable condition for a large stream flow.

The method used in calculating the precipitation of each basin was to select such stations of the United States Weather Bureau as were within it, and from them to pick out a number from the different sections of the basin, which would show the average conditions. From the records of these, it was possible to arrive at an approximation of the mean annual rainfall for the basin in question. The number of stations selected necessarily varied widely with different basins. In a small basin, with comparatively uniform conditions throughout, a few stations sufficed, while in a long basin, with widely varying conditions, such as that of the Columbia River, a greater number of records was required to determine the mean precipitation.

The stream measurements are those secured by the government at its gauging stations on the different rivers. The volume of the discharge is computed by securing a profile of the stream bed at the gauging point, and then placing on some permanent object a gauge which will read the height of the water. Daily readings are taken to ascertain the cross-section of the stream, while the speed of the current is determined with a current meter. After a number of discharges have been computed, a rating curve can be drawn which will give the discharge directly from the gauge height. Where the gauge is at a dam or weir, somewhat different methods are used, the flow being calculated by formula. Unfortunately, these gauging stations are rarely at the mouths of streams, and as the run-off for the entire drainage basin of the stream is not given, care must be taken to specify above what point the data apply.

Steam discharge is commonly given either as foot-seconds of flow, which is the number of cubic feet passing a given point in a second; or as the average total inches in depth of water flowing from the entire drainage surface during a stated length of time. This latter method has been followed in this paper, in order that the results may be directly comparable with the precipitation records.

Rainfall measurements are always given in inches of depth during a stated time, usually a year. Accordingly, the precipitation of an entire drainage basin is expressed in inches over its area.

The sources of error in precipitation records are several. In the first place, a rain gauge can cover only a few square inches of ground, and to obtain accurate results a large number of gauges in the same district would be necessary, which is usually impracticable. The elevation of the gauge above the ground also has an important bearing on the accuracy of the measurements. The gauges should be kept as near the ground as possible, whence records of rainfall taken on the tops of buildings are of little value.

The fact that many streams have their headwaters in the mountains adds to the difficulty of securing reliable records, as there are few stations in the mountainous regions, and these are generally confined to the valleys.

The accuracy of stream measurements depends upon the type of gauge used. If at a weir or dam, reliable measurements can be obtained, generally within an error of five per cent. At other gauging stations the results are not always so accurate, and the error may range up to 20 per cent. in exceptional cases. The main cause of this trouble is the constant shifting of the bottom, which renders the cross-section used in the computations inaccurate unless frequently corrected.

The data in the tables accompanying Mr. White's article were compiled in this manner: Following the name of the river comes that of the gauging station above which the data are computed. In the third column is stated the area of each river basin in square miles, and in the fourth the percentage which each basin constitutes of the whole drainage district. This is done for the purpose of giving due weight to the larger streams. The fifth column records the average annual rainfall of each basin, in inches, during the five years 1906 to 1910 inclusive, except in a few cases in which the average is based on only three or four of these years. The sixth column gives the annual run-off of each basin, averaged on the same five years; the figures represent inches in depth over the area of the basin above the gauging point. The ratio in the seventh column is obtained by dividing the average run-off by the average rainfall for the five years, not by averaging the ratios of the five years. The product in the last column is computed by multiplying the percentage area of each basin by its average ratio; hence the sum of this column represents the mean run-off ratio of the district.

It was found convenient to follow the divisions of the country made by the Geological Survey, and the streams have accordingly been grouped into the following districts: North Atlantic; South Atlantic and East Gulf of Mexico; Ohio River; St. Lawrence River; Upper Mississippi River; Hudson's Bay; Missouri River; Lower Mississippi River; Western Gulf of Mexico; Colorado River; Great Basin; Pacific Coast in California; North Pacific Coast.

From a study of the tables and a consideration of the basins of the individual rivers, some conclusions can be derived as to the various factors determining the run-off of a stream. The influences operating on the discharge of a river basin are too intimately associated and involved to allow an exact statement as to their respective importance, but certain general relations can be shown, and the relative importance of the factors judged approximately.

Run-off is, of course, primarily dependent on precipitation, but to say that the run-off varies directly as the rainfall is a broad statement which statistics fail to support. This is true, not only for different drainage basins,

but even in the same basin. Thus in the Penobscot River, above Millinocket, Me., in 1906, with a rainfall of 41.9 in., there was a run-off of 18 in., or 43 per cent., while during the next year, with a rainfall of 42.1 in., the run-off was 26.9 in., or a ratio of 64 per cent. Cases so extreme as this, however, are of unusual occurrence and are due to outside influences. Ordinarily it can safely be said that the per cent. of run-off in any particular stream will increase with an increase in rainfall. This is well illustrated by the Columbia River, which shows the following variation:

Year.	Rainfall.	Run-off ratio.
1906	21.5	45.6%
1908	24.2	49.0
1909	24.1	50.2
1907	26.1	52.1

Even though varying with the rainfall, the run-off is not directly proportional to it, but shows much greater variation than the rainfall ever does. The maximum annual rainfall rarely exceeds four times the minimum, while the maximum run-off may exceed the minimum by several times that amount. If the rainfall and run-off should be plotted for a period of years on an equal scale, the curve of the rainfall would be found to be much the more irregular, with far sharper changes. An example of this is given by the Oconee River, above Dublin, Ga.:

Year.	Rainfall.	Run-off.	Ratio.
1906	50.1	19.6	.391
1907	45.9	14.7	.319
1908	54.3	25.2	.464
1909	49.1	18.2	.369
1910	43.3	12.4	.288

Of even greater importance than the total amount of the rainfall is its distribution throughout the year. A stream which has its precipitation concentrated in a few months will yield a higher percentage of run-off than a similar one with its precipitation distributed evenly throughout the year. The causes for this are apparent. In the former case, evaporation has a smaller opportunity to act on the water, since in a rainy season evaporation is at its poorest efficiency. Also, as the ground can hold only a certain amount of water, when it becomes saturated the remaining water can flow off as a surface discharge.

An example of this principle can be found in the Merrimac of Massachusetts and the Kaweah of California. With nearly equal annual rainfall of about 32 in., the Kaweah has 33 per cent. higher run-off, the ratios being respectively 0.514 and 0.714. This is due to the concentration of 83 per cent. of its total rainfall into the months from November to April, while in the Merrimac basin the precipitation is distributed very nearly equally throughout the year, with 26 per cent. falling in spring, 24 per cent. in summer, 25 per cent. in autumn, and 25 per cent. in winter. This distribution of the rainfall is of the greatest importance, and special emphasis should be placed on it in calculating water supplies.

One reason for the increase in the ratio of run-off with higher rainfall is found in the evaporation, which remains nearly constant from year to year, irrespective of the amount of precipitation. The explanation of this is that conditions favorable for high evaporation, i.e., heavy rainfall and high temperature, rarely occur together. Due to this the evaporation of a wet year is about equal in amount to that of a dry, hot year. This uniformity of evaporation, so noticeable as between years, is not found as between seasons of a single year, when, on the contrary, great differences occur. In the basin of the Sudbury River of Massachusetts, evaporation during the summer is six times as great as during the winter, owing chiefly to the higher temperature and greater amount of sunshine during the former, and to the occurrence of ice during the latter season.

The evaporation of different streams varies widely, being dependent upon a number of separate factors. The most important of these is the temperature. Evaporation is directly proportional to the temperature, and will therefore be higher in warmer regions, other things being equal. It is even sufficient, in very hot regions, as some parts of the Great Basin, completely to exhaust the streams, leaving no flow in the river bed. The velocity of the wind also has an important influence on evaporation. Other factors of major importance are the roughness of the surface, the amount of sunshine, and the area forested.

Numerous attempts have been made to construct formulas by which to compute the run-off of streams from the precipitation records. Several of these are in use, but they are inaccurate and require important modifications for each stream. A formula for one stream may give fair results for a neighboring one of similar character, but to apply it to a stream in a different section of the country would be futile. The only reliable way to ascertain the run-off from rainfall data is to construct a curve for the particular stream from the records of former years, and use it as a standard.

The influence of topography on run-off is hard to gauge, as it is closely associated with other factors. It is probable, though, that this is one of the less important agents in determining stream flow. Roughly, it may be stated that in a steep basin the run-off will be large but very irregular, while in a flat basin the run-off will be less, but more uniform.

Two streams which flow over the same geological formation will be found to have a close resemblance in flow. The character of the soil and underlying rock is chiefly important by its ability to hold the rain in the form of ground water. Igneous and other massive rocks, such as the pre-Cambrics of the upper Hudson valley, give little opportunity for the rain to penetrate them, and therefore yield a relatively high run-off. At the other extreme, very porous rocks, as some sandstones and highly jointed limestones, yield little or no surface flow, but conduct the water at a deeper level, returning it to the surface at a lower point, possibly in some other drainage basin. These rocks afford a more regular flow to the streams, but the opportunities for loss are greater, and the ultimate total run-off is somewhat less than where denser rocks occur. Likewise a sandy surface soil yields a more uniform but smaller flow than where the soil is clay.

An interesting example of the influence of geological formation on the run-off is found in the basin of the Mohawk River, where those tributaries flowing from the granitic area to the north of the stream have a greater run-off than those coming from the Devonian shales to the south. It must not be forgotten, however, that the area to the north is much more heavily forested, and its greater flow is undoubtedly partly due to this influence.

The proportion of a drainage basin that consists of lakes and marshes has a modifying influence on stream flow, through the ability of these to store excessive rain-

fall and to distribute its flow over a longer period of time. On the other hand, due to increased evaporation over a water surface, lake area decreases the total run-off of a basin to an appreciable extent. An example of high evaporation is seen in the Oswego River basin, of which 10.6 per cent. consists of lakes and marshes, where the evaporation amounts to 28 in. annually. The equalizing effect of lakes on stream run-off is also well illustrated in the basin of the Androscoggin River, which has 69 square miles of lake surface.

Lakes and marshes are not the only means of storage, for over most of the country large quantities are stored in the form or ice and snow, occurring as loose drifts in the lowland, which will melt and will find their way to the streams at the first thaw, or as deep solid drifts on the mountain ranges, or more rarely in the form of permanent glaciers. Snow of the first type serves only to swell the already high streams of early spring, without having any beneficial character. If of the latter types, the melting period is much later and more protracted, which is of great service in maintaining flow during the summer months when all other agencies are working toward the reduction of the discharge. It is a general rule that streams which have their sources in the mountains maintain a more constant summer flow than those rising in the lowlands. Nowhere is this better illustrated than in the streams of the Pacific Coast, where the mountains of the Coast Range are close at hand, and contain the headwaters of most of the streams.

That the vegetation of a drainage basin is of great importance in determining the amount of run-off is generally accepted, but whether the forests increase annual rainfall, as commonly believed, has not been proved. Indeed, it is now considered very doubtful whether any difference in rainfall can be traced to the influence of vegetation. The real value of vegetation, and particularly of forest growth, is in restricting the evaporation of the rain that does fall. Plants somewhat counterbalance their effectiveness in this direction by the water which they consume themselves, but the balance is well in their favor; and if, of two similar watersheds, one is heavily forested and the other is not, the run-off from the forested basin will exceed that from the other.

The effectiveness of the vegetation depends largely upon its character. The best type is old coniferous forests which allow little wind and less sunshine to penetrate their depths. Where extensive areas of such forests occur the run-off is sure to be high. Deciduous growth is not so influential, yet is still of value, and even cultivated fields are of some, though limited importance. The means by which the increased run-off is produced are several. First is the restriction of evaporation, due to the inability of the wind to circulate freely among the trees, to the maintenance of lower temperature and higher humidity during the summer months, and to the protection which the foliage gives from the sunshine. Aside from the lessening of evaporation, forests provide conditions favorable for the accumulation of snow drifts and their preservation until after the time of the spring floods. The ground-water circulation is also increased by forests. Examples of high run-off from heavily forested regions are common, but the Machias, Mohawk and Umpqua Rivers are excellent illustrations.

In spite of the prominence of forests in governing the run-off from an area, other factors may combine to overcome its influence; as a result, some basins show low or irregular run-off notwithstanding their being heavily forested. This is well shown by the streams of western Oregon and Washington, which, although well protected by forests, are subject to floods, due to heavy and concentrated rainfall.

The recent disasters in Ohio and Indiana have brought the general subject of floods prominently before the public mind, and the study of their causes and occurrence is of special interest. It has been noticed of late years that floods have been increasing in frequency and a study of the records of almost any stream subject to floods will prove this. On the Allegheny River, during the period from 1874 to 1890, floods occurred in only three years, while during an equal period, from 1891 to 1907, there were ten years when floods occurred. Likewise, on the Savannah River, from 1876 to 1890, there were three years with floods; while during the years 1892 to 1906, there were five years with floods. These rivers indicate fairly well the change in conditions throughout the eastern states.

The explanation of this increase must lie in a change of one of the influences governing run-off. Records show that rainfall and temperature have not changed; the topography and geology of a river basin are permanent, for this discussion; artificial agencies tend to check rather than encourage floods; hence the prime cause must be a change in vegetation, chiefly deforestation. The records sustain this supposition by proving that it is those very basins that have been most denuded of their forests which record the greatest increase in the number of floods. Thus, on both the Allegheny and the Savannah river basins large lumbering industries have been at work during recent years, and the increase in the number of floods can be traced directly to this cause.

In conclusion is should be emphasized that the solution of the problems herein discussed is not final, because reliable records over long periods of time are not available, and little attention has yet been paid to this important subject.

In a report made by State Engineer Bensel, it is announced that New York State will have invested in its barge canal, when complete, $86,000,000, an increase of nearly $10,000,000 over the original estimate in 1913. He recommends also that the United States federal government be asked to deepen United States waters at Oswego, Albany and Whitehall; and favors also the conversion of all old canal lands into boulevards and parks.

L. R. Grabill, superintendent of suburban good roads, Washington, D.C., considers that the prime factors which should determine the selection of a type of road surface, when selection is not limited by any necessity for giving undue preference to any factor, are; first, the volume and nature of the probable traffic over the pavement; secondly, conditions incident to the location of the pavement; including the character of the adjacent land and improvements, the character of the foundation, the kind of adjoining pavements, the ruling gradients, the climatic conditions and especially the availability and cost of different materials at the work; thirdly, the characteristic of the surface which will adequately meet physically, hygenically and aesthetically the conditions expressed in the two factors first named; and last, the quotient obtained by dividing the total estimated traffic to be carried per unit of width into the cost per unit of area of the pavement during its probable life; including first cost and interest on the same, special surface treatment for dust suppression or other purposes, and any necessary repair until replacement; but not including the cost of cleaning.

WATER POWERS OF MANITOBA.

THAT Manitoba is richly endowed with numerous water-powers has been generally known, but previous to the investigations of the Water Power Branch of the Department of the Interior of Canada, their extent and magnitude have only been approximated. Recognizing the great value of such powers, and with a view to the power requirements of both the present and future, a complete study has been made of certain power rivers, and is being made of all other power rivers throughout the province. In such studies it is the aim of the Department to form a comprehensive scheme contemplating the maximum development of the total head available upon a river.

A general summary of the water-power resources of the province forms a part of a report prepared recently by the Department for the Public Utilities Commission of Manitoba. The information given here is extracted from the report. *The Canadian Engineer* for February 12th, 1914, published another portion dealing with the power possibilities of the Winnipeg River as a part of the same investigations.

The preparation of the material in the report, with the exception of that relating to the Winnipeg River, was commenced by Mr. D. L. McLean, Chief Engineer of the Manitoba Hydrographic and Power Surveys. Owing to his resignation in October last, most of the work devolved upon the assistant engineer, Mr. S. S. Scovil, whose enthusiastic co-operation made possible the speedy completion of the whole, in order that it might be in the hands of the Public Utilities Commission by December 15th, 1913.

The great power possibilities of Manitoba are due to the geological and topographical features of the province. The central portion of Manitoba acts as a collecting basin for the waters from an immense drainage area. This vast area extends from the Rocky Mountains practically as far eastward as Lake Superior; it also comprises a great portion of the Northern States and reaches into the northerly lands of Western Canada.

As these waters reach the central portion of the province, a depression occurs between the prairie steeps and the Laurentian plateau, through which an extensive fall is available for power development. Lake Winnipeg forms the reservoir into which is collected practically all the runoff from the above drainage area. From this lake to Hudson Bay the flow is concentrated in the Nelson river, on which a drop of approximately 700 feet occurs.

It is thus apparent that the major portion of the powers throughout the basin are concentrated within the lower portion of the drainage area, or more particularly in Manitoba.

The powers are naturally separated into two divisions, viz., those occurring on the rivers draining into Lake Winnipeg, which are situated in the older or southern portion of the province; and secondly, the powers which occur in the northern portion lying in the drainage from Lake Winnipeg. Under these two divisions the estimated powers of the province are tabulated below.

It should be noted that while on many rivers, possible power concentrations have been investigated, and an estimate of the available power is given for various sites, yet, as future investigations will show, further power may be available on such rivers. Again, in the case of other rivers, no surveys to determine the extent of concentration available have as yet been made, and in these cases where a record of the flow has been obtained, an estimate is made of the power available per foot head. In many cases the power has been estimated both for the extreme minimum flow and for the lowest monthly mean flow of the highest six months of the year as obtained from the present record of discharges.

The horse-power has been calculated for a turbine efficiency of 80 per cent., while no estimate has been made as to the power available during short periods of high or peak loads, since this would be impossible without a knowledge of the circumstances for which the power might be desired. The powers on the Winnipeg river have been considered on a 75 per cent. efficiency basis for reasons set out in the treatment of that river. (See *The Canadian Engineer*, February 12th, 1914.)

The data for these tables, and also for the more detailed description of the rivers as given in the following chapters, has been secured in the field by the Manitoba Hydrographic and Power Surveys, and office compilation in Winnipeg and Ottawa.

The following tabulation of the powers in the province is not intended to fully cover the subject, as many rivers are as yet to be investigated:—

POWERS OF SOUTHERN AND CENTRAL PORTION OF PROVINCE.

Table No. 1.—Existing Water Power Developments.

River.	Plant.	Power developed. H.P.
Winnipeg	City of Winnipeg*	20,800
Winnipeg	Winnipeg Elec. Ry. Co. ..	26,500
Little Saskatchewan.	Brandon Elec. Light Co..	500
Little Saskatchewan.	Minnedosa Power Co. ..	500
Shell	Assessippi	50
	Total	48,350

*The city of Winnipeg's plant can ultimately supply, with a regulated river, 76,800 24 hr. power.

Table No. 2.—Possible Water Power Developments.

Winnipeg River.

Upper Long Spruce Rapids	181,150
Upper Long Spruce Rapids	235,495
Upper Limestone Rapids	149,450
Lower Limestone Rapids	185,680
	2,548,505

During 1912, a thorough study of the advisability of paying close attention to the air consumption of the machine drills in a mine, especially where power is purchased, as shown by the experience of the Central Mining-Rand Mines group on the Transvaal (Journ. So. African Inst. of Eng., November, 1913), was made; and the new methods of handling the machines was adopted. The air consumption for all purposes underground was reduced to units of 3¼-in.-piston drill shifts. The average number of such units was between 75,000 and 80,000 per month over the year. The air was purchased in so-called air units, representing energy to the extent of 0.641 kilowatt-hours. The consumption of these units was about 11,500,000 per month and the average consumption per machine shift was reduced from 163 to 138. This represents a clean saving of $0.25 per machine shift, over $225,000 in a year's time. This would seem worth while.

CONSERVATION OF COAL IN CANADA.

The Commission of Conservation has now in press a report on the conservation of coal, according to the address of Hon. Clifford Sifton, at the last annual meeting of the Commission. This report catalogues briefly the methods followed in operating the principal coal mines of Canada. Emphasis is laid on the advantages of the leasehold system of granting coal areas which is in vogue in Nova Scotia, and the adoption of a similar system is recommended in other provinces, more especially in Alberta, with a view to stopping the wasteful methods of mining coal which obtain in certain districts.

Attention is also directed to the advantage of briquetting coal, in order to prevent the waste of slack; and the advantages of the by-product coke, even over the type generally in use, are set forth.

The fact that the practice of briquetting coal has not yet been followed on any considerable scale in Canada is an illustration of the difficulty of securing the introduction of well-proved, economic methods which have been in use in older countries for many years. It is hoped that a beneficial change in this respect will come about in a short time.

In addition to visiting the different mining plants for the purpose of getting information upon which the report respecting the conservation of coal is based, W. J. Dick, B.Sc., Mining Engineer of the Commission, in acting as guide in connection with the visits of the International Geological Congress to the coal mines of western Canada, had the benefit of gaining the opinions of foreign scientists in regard to the conduct of the coal mining industry.

NEW PULP MILL ON THE ST. LAWRENCE.

On the south side of the Gulf of St. Lawrence, about sixty miles back from the end of land, the St. Lawrence Pulp and Lumber Corporation is erecting a plant which, when finished, will represent an investment of close to a million dollars. There is an irregular group of buildings, mostly one-story, and measuring something like 900 by 200 ft. in plan, forming a complete pulp mill for making high-grade bleached sulphite pulp, together with a digester building covering digesters reaching 160 ft. above the ground. All of this is now being built by the Aberthaw Construction Company, of Boston, and is to be finished by next September. The buildings have concrete exterior, the interior structure being largely of structural steel, with yellow pine roofs.

There is to be an independent steam turbo-generator plant, giving power for both the pulp mill and a saw mill, which is being erected separately. A private railroad is to supply the mill with logs from the extensive timber and pulp-wood limits of the company, aggregating some 500 square miles. The Dominion Government has undertaken to develop a harbor for safe wharfage for ships up to 6,000 tons burden.

Canadians may praise the condition of English roads, but the following facts show the Englishmen see plenty of room for improvement. Proceeds of the petrol tax are enabling seven counties to spend $4,000,000 this winter, on road making, with the object of creating a smooth, waterproof, dustless surface. The road board, which Mr. Lloyd George created, has already made grants of $22,500,000 from the imperial taxation for strengthening the main roads to meet the requirements of modern traffic.

CONTENTS OF THIS ISSUE.

OTTAWA'S TEST FOR INTELLIGENCE.

A plebiscite on a question of civic concern cannot be said to achieve its purpose unless the voter has a clear conception of its fundamentals in order that he may poll his vote in accordance with his convictions created thereby. To be able to vote intelligently is the chief desire of every enfranchised citizen. A city council should assist the ratepayer to a clear understanding of the projects it may have under consideration, especially when it contemplates acting according to the vote of the citizens. Perhaps a more illustrative instance could not readily be found of a city council taking for granted that the man on the street can weigh and judge, with competence, questions which tax the agile and discriminating capabilities of the experienced engineer, than that which has appeared in connection with the Ottawa water supply situation. The city's serious position has brought forth reports from engineering experts on five separate proposals. They have appeared at intervals during the past 3½ years. Each in turn was subjected to a round of discussion and criticism which left the layman in such a quandary that the water supply situation has continued substantially unchanged.

On March 9th, the citizens will vote upon the acceptance of any one of the five schemes or the rejection of them all. The reports upon them are being presented in their entirety through the medium of the daily press. They occupy 4½ closely printed newspaper pages. The ratepayer is supposed to select the scheme best adapted to the needs, and likewise the finances, of the city. He is obviously expected to appreciate the significance of each, to differentiate between considerations of purification, precipitation, run-off, pipe line construction, pumping installations, future population, annual operating costs, fixed charges, etc. Then he is supposed to place himself on record as being in favor of one and against the others, influenced only by his own intelligent comparison.

Rather than subject each ratepayer to an ordeal which he is quite incapable of satisfactorily accomplishing, how much better it would have been for the City Council of Ottawa to have engaged a consulting engineer to condense and standardize the voluminous reports so that the citizens could then make an intelligent comparison and understand the meaning of their vote. This, however, is what the City Council considered and decided not to do.

THE KINEMATOGRAPH IN SCIENTIFIC RESEARCH.

Professor Anderson, of the University of Toronto, has favored us with an interesting description of the newly installed kinematograph which will add materially to the facilities at the University for exhaustive scientific research. The article on page 415 of this issue will doubtless be found very instructive by our readers, many of whom can realize at once the important bearing such an apparatus will have in many of the studies which enter into university training.

The very great importance of visualization in teaching is so universally recognized that projecting lanterns form a most important part of the equipment of every scientific institution in the country, and every lecturer who wishes to make his subject clear and attractive feels bound to provide plenty of pictorial illustration. However, it must be admitted that while the stationary picture

forms an invaluable adjunct to a description of an object, be that what it may, that picture fails to convey any adequate idea of a process, of an event, of machinery in motion, of people in action, in short of life in general. The photograph exhibits all life and motion as instantly arrested—a sort of cold-storage representation, if one may use the expression.

With the kinematograph, however, all is different, and we see representations of events taking place, of processes being carried on, of machinery in motion and of people moving about as in actual life. Perhaps it is not too much to say that the kinematograph is as great an advance on the stationary lantern slide or photograph as the latter was on the laborious written descriptions that preceded the discovery of photography.

There is not a branch of scientific work in which this facile method of illustration may not be used with the greatest advantage. In elementary education where the child learns most readily through observation, we may use moving pictures to teach history and geography, to illustrate manual training and handicrafts of all sorts. In more advanced work, engineering in all its branches offers a fruitful field for this method. In the laboratory we may take records of tests of all sorts and study every phase of the reaction at leisure afterwards; industrial plants may be photographed and exhibited in action in the class room; field operations of all kinds may be similarly shown. In the domain of medicine there is also abundant scope for the moving picture, whether we are dealing with objects of large size or minute organisms that are only visible through the microscope. In military operations or naval manoeuvres there is likewise an ample field of usefulness for this method. The naturalist will welcome the kinematograph as an unrivalled method of studying and illustrating the habits and motions of animals and the growth of plants. Many other possibilities will no doubt occur to the reader, but enough has been indicated to show the universality of the motion picture in educational work and it is not too much to predict that we shall soon see every technical school and university equipped with a paraphernalia for this work as the University of Toronto has been equipped.

ELECTRICITY IN BLASTING OPERATIONS.

Electric ignition in the blasting of charges in mining, tunnelling and similar operations, has greatly assisted in the prevention of accident and disease by permitting the withdrawal of operators from the sphere of danger. Not only from the explosion itself but from the dangerous gases which follow perfect or imperfect detonation, does it afford more and better opportunities for safety, thereby becoming a factor of great importance. When blasting gelatine has been properly detonated the products are chiefly CO_2, H_2O and N_2. If it is merely burnt the products of combustion are CO_2, CO, N_2 and NO. In either case the carbon dioxide causes asphyxiation; carbon monoxide is a strong poison, and the nitrogen compounds, if inhaled, cause intense irritation of the air passages, bronchitis and pneumonia.

In a properly organized system of electric ignition, blasting accidents are reduced to a minimum, and the underground worker is requested to withdraw to a place of safety before a single shot is fired.

The introduction of the ignition of blasting charges by electricity is a subject that appeals to engineers, it being associated with the history of electrical engineering itself. After the discovery of the primary cell by Volta, the thermal effect obtained by interposing in the circuit of a Voltaic battery a short piece of wire of high resistance was noticed by Professor Hare about 1822. This discovery was immediately used as a means whereby blasting charges could be exploded.

The discovery by Dr. Oerstedt in the year 1820 that a magnetic needle tended to place itself at right angles to a current of electricity, and the subsequent development of this discovery by Faraday led to the introduction of magneto exploders. According to records obtainable from about the year 1840 onwards the progress of the art alternates between improvements in the apparatus for producing the necessary current, and the means of starting the explosion.

While British and American engineers developed apparatus which depended upon the heating effect of current for its operation, European engineers, chiefly in Austria, sought efficiency in systems of ignition by sparks, from which were evolved the two distinct methods known as high and low tension systems. In the former, the terminal wires are bridged by combustible as well as electro-conductive composition of fairly high electrical resistance. In the low tension exploder-fuse the terminal wires are metallically connected and surrounded by highly combustible mixture.

LETTER TO THE EDITOR.

Micrometer Method of Surveying Water Routes.

Sir,—The article by R. B. Sinclair under the above heading in your issue of February 12th, will bear some elucidation. In the past the micrometer has not been used very extensively and to many surveyors of to-day is practically unknown; consequently, a brief description of the instrument and the principles of operation may not be out of place.

For the micrometer measurement of distance a gradienter attachment on the vertical arc of a transit might be used in conjunction with an ordinary or target levelling rod, but the stadia method is preferable. It is, however, the double-image micrometer that is now under consideration.

There are two types of instruments in use, the Rochon, used by the Dominion Geological Survey, and the Canadian modification of the Luguel, introduced by Jas. Foster, of Toronto, some years ago.

The first consists of a long telescope fitted with thick double refracting prisms. The angular measurement is small and is read on a graduated scale from a pointer sliding longitudinally in a slit in the telescope by a rack and pinion motion. Too much light is absorbed by the prisms in this type of micrometer, and there is a consequent dimness of the images which is the reverse of what is required in a good instrument. The other type of instrument has a split objective, one cut diametrically in halves and each half fixed to a metal frame holding each semi-objective. Motion is communicated by a shaft screw of which one-half is left hand and the other, right. Each part turns in a corresponding nut fixed to the frame thereby moving the objectives in opposite directions.

Targets and Base.—Without expanding on the operation of the instrument as explained by Mr. Sinclair, there are a few important points which he does not touch in his description. When the vernier reads zero objects appear identically the same as if viewed through an ordinary inverting telescope. Two targets attached to a rod will appear as four targets as soon as the split objectives are moved vertically by the screw. This motion

is continued until the two central images coincide, when the angle is read in terms of revolutions of the micrometer screw.

The product of the target base and the micrometer reading is a constant. Thus, after checking a few readings at different distances, a table can be compiled to suit individual requirements. Targets may be attached with screw eyes to any pole cut in the bush—a dry tamarack serves the purpose well—and the longer the target base the better. When the pole is held vertically the lower target should not be closer than 5 or 6 feet from the ground, hence, a pole with base longer than 15 links or 10 feet will be found very inconvenient to handle from a canoe.

The style of target is important. Bevelled rectangular frames fitted with ground glass have been used, but glass is fragile at best. Translucent celluloid answers the purpose better. The frame should be at least 15 x 8 inches. Japanned galvanized iron is better than wood, because the latter will not stand rain. The object in using a translucent target is to allow the sun's rays towards evening to penetrate the marginal frame, otherwise the targets cannot be seen when pointing the telescope towards the sun. The writer has had satisfaction using an enamelled metal disc with one half white and the other half one-third red and two-thirds black. With these targets a long horizontal line can be obtained by slightly rotating the telescope, thus securing perfect superimposition. The object in using the red is to find the targets more readily when snow is on the ground, and particularly at long range.

Results.—A comprehensive paper on the "Micrometer Measurement of Distances," by Wm. Ogilvie, D.L.S., appeared in the 1887 Proceedings of the Association of Provincial Land Surveyors of Ontario (O.L.S. since 1893). Mr. Ogilvie points out that the errors would probably be in the inverse ratio of the lengths of base used, were it not for the fact that atmospheric moisture, density and temperature are varying quantities which constitute the greatest barrier to reasonably uniform results with any form of micrometer.

With a 15-link base and fair atmospheric conditions, distances of 40 chains can be determined within five or six links of error. The error, however, may be ten times that amount on a bad day even though we use our utmost care. Refraction affects the lower disc more than the upper under certain atmospheric conditions. Other hindrances, sometimes impossible to remedy, are improper light and shade and bad background.

By taking shots not exceeding twenty chains equally good results can be obtained for shore line traverses where chaining would be tedious and inconvenient. In very rough country better and quicker results are obtainable if the micrometer is used in preference to the chain.

For exploratory work such as river and lake traverses, the writer has used the micrometer with satisfaction in conjunction with transit, compass and plane table for azimuth or bearing. On a river traverse, where two canoes were used and the entire camp equipment carried along, six miles of traverse per day was the average work accomplished. The river in question was the Wanapitei, a stream full of rapids after turning south, necessitating numerous portages. The courses averaged 8 per mile or 10 chains each, and the error in distance did not exceed two chains across a six-mile township. On larger streams it would be quite possible to traverse ten miles per day.

W. R. ROGERS, Topographer.
Bureau of Mines, Toronto, February 28, 1914.

THE KINEMATOGRAPH AT THE UNIVERSITY OF TORONTO.

By G. R. Anderson,
Associate Professor of Physics.

THE evening of February 6th, witnessed the first public use of the new moving picture installation at the University of Toronto. The occasion was that of a lecture by F. N. Speller, B.A.Sc., Engineer of the National Tube Company, of Pittsburg, on the manufacture of steel tubes and pipes, delivered to the Engineering Society of the University and the Central Railway and Engineering Club of Toronto. The exhibition included all phases of the work, from the mining of the ore to the testing of the finished product, and was unique from an educational point of view, and thoroughly appreciated by the large audience present.

In view of the widespread interest evinced in this method of illustration, a general description of the various parts of the installation may be of interest to readers of *The Canadian Engineer*.

The camera for the taking of films is illustrated in Fig. 1. It consists of a leather-covered body containing the usual film-boxes, each capable of holding 60 metres of film. The lens is an anastigmat of focal length (2 in.)

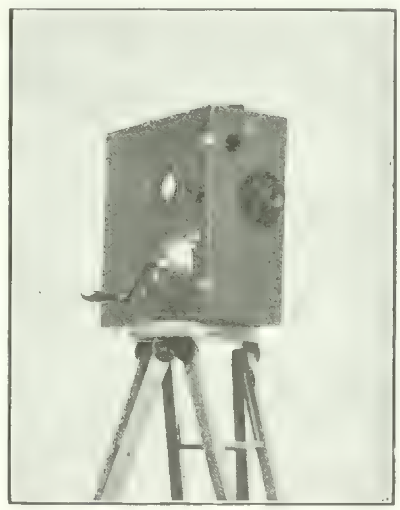

Fig. 1.

and having an aperture of 3.5, thus permitting of exceedingly rapid exposures. The finder is large, and so placed that the field may be observed throughout the exposure. The film is ordinarily driven by a crank, but provision is also made for motor driving when desirable, as will be seen by the triple-step pulley, shown in the illustration. An indicating dial on the side of the camera shows the amount of film being used.

The equipment also includes the apparatus necessary for the animated photography of microscopic objects, such as bacteria, for which purpose the parts are arranged as shown in Fig. 2. The stand is entirely of metal, and sufficiently heavy to be perfectly rigid. The camera is attached to a pair of vertical rods in such a way that by loosening the lever L it may be instantly swung to one side, leaving the microscope in position for eye observation, and as quickly returned to place. The lens of the camera is removed and connection with the microscope established by means of a small leather bellows, while an adjustable lens inserted in the side of the camera permits the observer to watch the microscopic field at the same time that the photographs are

being taken. The film in the case of microscopic work is preferably driven by a motor operating against a worm gear, whence the motion is transferred by a belt to the camera. The motor is controlled by a foot-switch, so that the operator has both hands free to take care of the adjustments of the microscope and lamp. The light for the illumination of the microscopic field is furnished by a small arc lamp, the light from which passes through

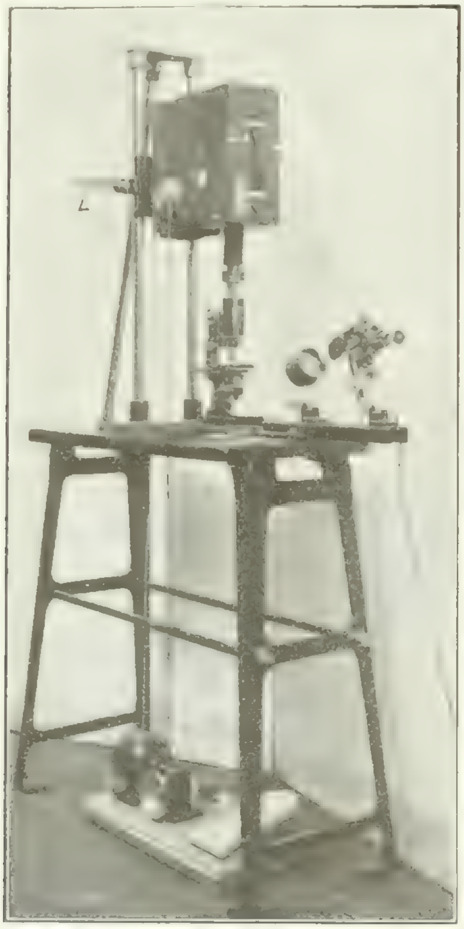

Fig. 2.

a condenser and a liquid cell to absorb the heat and, if necessary, the violet and ultra-violet rays. All these accessories move on a planed optical bed and are readily adjustable to suit requirements.

The microscope is a Zeiss of the large barrel type, specially designed for photo-micrography. It has a photo-micrographic stage, adjustable by rack and pinion in two directions, its position being indicated by verniers reading to 1/10 mm., and furnished with an achromatic substage condenser, which can be instantly swung out if not required. The optical equipment consists of 4 apochromatic objectives and 6 compensating oculars, giving magnifications ranging from 31 to 2,250. Provision is also made for using polarized light if required.

The projector (Fig. 3) for exhibiting the finished films is of particularly substantial construction to insure steadiness and rigidity. The stand is of metal, and has a tilting top with a range of about 17°, permitting of both elevation and depression. The lamp-house is constructed of sheet iron lined with asbestos, ventilated by means of a rising roof provided with a wire guard and closed at the rear by an asbestos curtain. The lamp is of the right angle type, provided with adjustments for tilting, raising and side-swinging the arc. The condenser is open-mouthed, of hard water white glass, and can be instantly lifted out of its bearings. The film fire-guard, G, is a distinctive feature of this projector. It is of two-ply steel, enclosing an interlining of asbestos, and extends from the upper magazine wall above the film exit to the base, so that there is no possibility of the film coming into contact with the lamp. The magazines are large and of very solid construction, consisting of spun steel without joints and lined with asbestos; the doors are securely locked, so that it is not possible for them to become unfastened accidentally. The film emerges from the upper magazine through a film-way of metal, closed by a clasp, and which is so narrow that in the event of the film taking fire the flame cannot pass up through this throat and set fire to the reel; the same construction is, of course, followed at the lower magazine. The winding of the film on to the lower spool is effected by a metal driving-rod geared to the main shaft. This is much more reliable in its action than the usual belt drive. Fig. 4 shows the left side of the machine with the cover of the Geneva movement removed. The special features of this

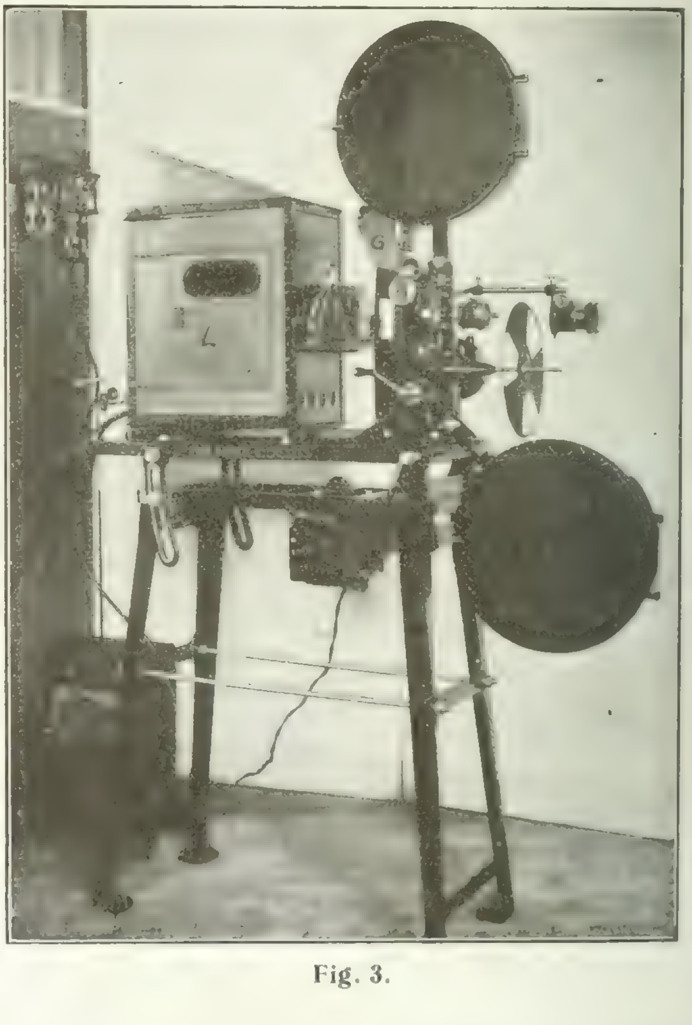

Fig. 3.

vital part of the mechanism are the extra large Maltese Cross and the roller bearing for it to operate on (ordinarily this roller is merely a pin); this eliminates friction, noise and wear of the parts; further, the whole movement is enclosed in an oil bath.

The machine is driven by a motor bolted to the framework and provided with a speed regulator, so that absolute steadiness of the film is secured over a wide range of speeds. The lamp-house slides on two planed rails, so that it can instantly be pushed over to the end

for the purpose of showing ordinary slides. These are inserted in a double carrier attached to the frame on which the condenser rests, and one slide may always be left in place while the film is being shown. There are two projection lenses of large aperture and flat field, one for the projection of the film and the other for the slides, the focal length of the former being 5 inches and of the latter 15 inches, so that the images from film and slide are of equal size. The adjustment of the mask to fit the film is accomplished by a rack and pinion movement operated by a large milled head, shown at A, Fig. 3. This permits

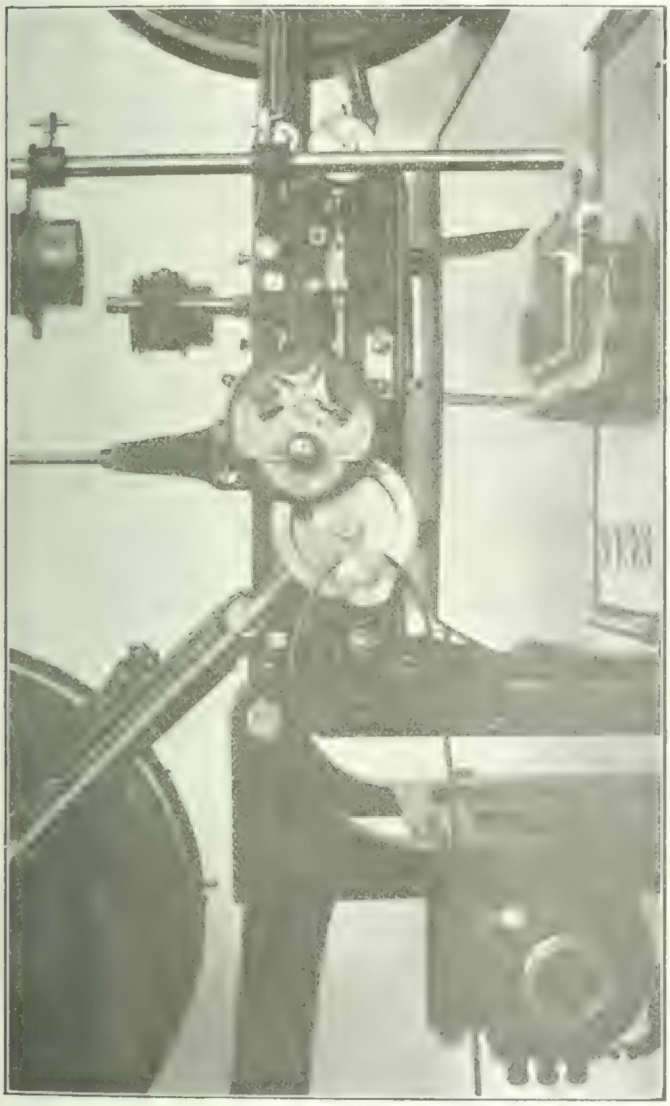

Fig. 4.

of the film being correctly placed without interfering with the position of the projecting lens or the mask, an exceedingly convenient arrangement in practice. The workmanship throughout the entire installation is of excellent quality, the gears are carefully cut, and the machine runs lightly and steadily with a minimum of noise.

A recent publication at Sydney, N.S., announces that the output at the several collieries of the Dominion Coal Company for the month of January was 347,000 tons. This is about 38,000 tons less than the output for January, 1913. The company's officials anticipate an increased output for this month, however, and it is believed the total will run over 400,000.

REPORT ON OTTAWA RIVER AS SOURCE OF SUPPLY FOR CITY OF OTTAWA.

On March 9th the City of Ottawa will take a plebiscite vote to ascertain the will of the citizens in the choice of water supply. The difficulties which the city has experienced in coming to a decision in this matter has been frequently commented upon in this journal. A new report has been submitted to the city council covering the latest scheme to be included in the vote next Monday. Mr. Arch. Currie, City Engineer, was requested by resolution of council a month ago to prepare a report on a proposal to derive the supply from the Ottawa River from a point not higher up than Britannia Bay on Lake Deschenes by an all-land pipe line route on the Ontario side of the river, to the present pumping station, the system to include a low-service reservoir and a rapid sand filtration plant.

The other four schemes are: The Thirty-One Mile and Pemichangaw Lakes, as reported upon by Sir Alexander R. Binnie and Dr. A. C. Houston; McGregor Lake, as reported on by Mr. Allen Hazen and others; mechanical filtration of the Ottawa River water, as reported upon by Mr. Allen Hazen; Lake Deschenes, without filtration, as reported upon by Arch. Currie, City Engineer.

Mr. Currie was instructed to report upon the feasibility of a plan to take the Ottawa River water from a point above the present intake and purify it by means of a modern rapid sand purification plant; to estimate the capital cost of providing such a purified supply, based on an average daily use of 25,000,000 Imperial gallons per day; to estimate the annual operating costs and fixed charges for pumping and purifying a supply of 25,000,000 gallons per day; and to estimate also the additional annual operating costs and fixed charges which would be incurred over and above present conditions.

The report states that in the vicinity of Ottawa the Ottawa River has a minimum flow known to be many times greater than the requirements of the city for a public water supply. The quantity available for this purpose may therefore be considered as unlimited.

The water of the river is colored yellow or brown by organic matter. It is a soft water having a slight odor and taste. The turbidity varies from month to month but for most of the year is not serious. It is also somewhat polluted, especially below the Chaudiere Rapids and Lemieux Island. Above these points the pollution is and always will be much less, and as far as natural rivers are concerned it is one of unusual purity for public water supply.

Mr. Currie refers then to a special study which he has made of the available data on the purification of waters similar to that of the Ottawa.

During his regime as city engineer of Westmount, the Montreal Water and Power Company installed a purification plant which has been in successful operation for the past few years. This plant supplies a colorless, purified water of excellent quality and at the rate of 25,000,000 gallons per day to the customers of the company, among whom are the citizens of Westmount. The water purified by this plant is, during a considerable part of each year, almost identical in character and quality with that of the Ottawa River at Ottawa, and is, in fact, almost entirely Ottawa River water.

The plant upon which Mr. Currie has estimated is of similar character and has operating conditions very like the plant at Montreal.

There are other purification processes which could be used for the water of the Ottawa River, but none of them are, for various reasons, so well suited to the local conditions as the type mentioned. In order to avoid the large amount of pollution in Nepean Bay and the necessity of delivering purified water under this portion of the Ottawa River if the purification plant be placed on Lemieux Island, the report recommends that the intake be placed at some point above the Little Chaudiere Rapids, with the purification plant on the mainland, and estimates were made accordingly.

General Description of Proposed Works.—The intake pipes, two in number, extend out into the river between the Little Chaudiere Rapids and Remic's Rapids. This point of intake reaches a part of the river where the conditions are favorable for minimum pollution. The water passing through the natural sedimentation basin of Lake Deschenes is partly purified by nature during this process and the point of intake has been selected with the object of taking full advantage of this fact. When the Georgian Bay Canal will have been built the purification due to this natural sedimentation basin will be even better owing to the larger area of lake created by the building of the canal works.

On the shore near the end of the intake pipe is situated the pumping station. This should contain electrically driven, low-lift turbine pumps of sufficient capacity to supply the purification plant at its maximum rate of working with provision for some spare machinery in case of breakdown. The low-lift pumps at present in use at Lemieux Island may perhaps be found suitable for part of the equipment after some modifications, in which case the estimated capital costs could be reduced accordingly. The electric current for the regular operation of these pumps could best be derived from hydro-electric units installed in the main pumping station.

When the Georgian Bay Canal will have been built it will be necessary to remove the pumping station from its first location to one above the elevation of the new water surface. This is not a serious matter and involves no special difficulty or great cost. The proposed location for the pumping station under these conditions is indicated on the plan. Under these future conditions the power required at this station will be reduced appreciably.

The transmission lines from the main pumping station to the headworks pumping station may well be carried on cedar poles treated to prevent decay. They should consist of 3-phase circuits in duplicate at a suitable voltage.

The estimates are based upon the use of steel pipes from the headworks pumping station to the purification plant and reservoir, and thence to the main pumping station. The quantity of water required under maximum conditions is such that an effective cross-sectional area of about 19 sq. ft. is desirable in the pipe line in order to provide for this quantity with some capacity for future growth. The smallest single pipe which should be used for this purpose is one of 60 in. in diam. My estimates are based upon using two pipes each 42 in. in diam., having an area equivalent to that of the 60-in. pipe, but giving a greater flexibility in operation and a good insurance against breakdown. The two 42-in. pipes will cost somewhat more than a single 60-in. pipe, but the extra expenditure is justified by the advantages gained. Cross-connections at intervals are provided for from one 42-in. pipe to the other, thus insuring flexibility in operation. In case of trouble occurring in either pipe line, or in case inspection or repairs be required, it will be necessary to shut down only a comparatively short length of

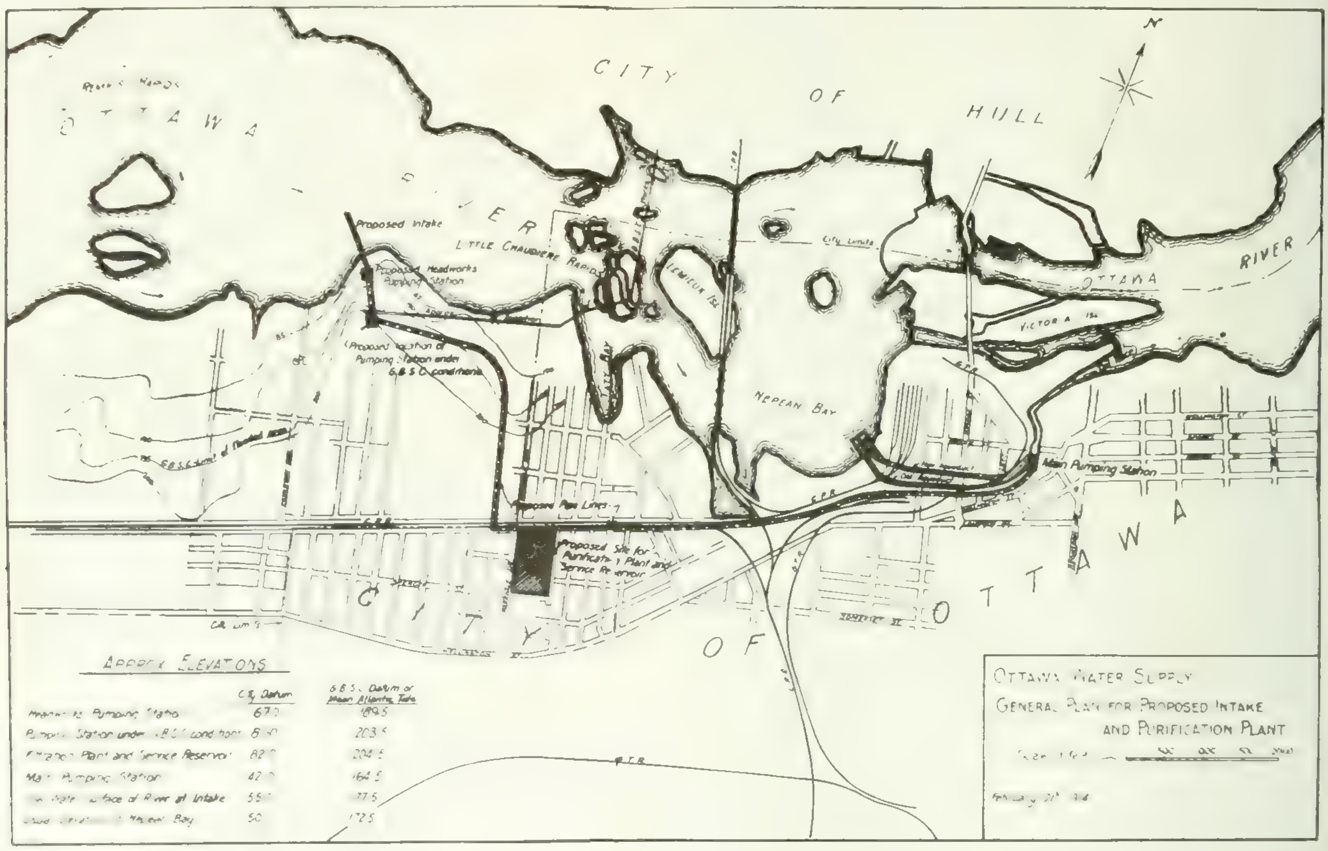

Fig. 1.

one pipe at a time, a proceeding which will effect the gross capacity of the pipes by only a small percentage.

Purification Plant and Reservoir.—The purification plant should consist of comparatively large sedimentation and coagulation basins designed with baffle walls to cause the water to flow slowly enough through the basins so that a large part of the impurities will be deposited in them. From the coagulation basins the water should flow by gravity to the filter beds and down through the sand in these to the clear water reservoir beneath. The coagulation basins, filter plant and clear water reservoir should all be covered on account of our climatic conditions and to prevent local pollution. Such additional machinery and appliances as are necessary in and about the purification plant require very little space and are simple in character. Two or three men per shift operate such a plant without difficulty.

The average daily output of water, 25,000,000 gallons, is much less than the nominal capacity of the plant estimated upon. The proposed plant can filter satisfactorily over 35,000,000 gallons per day and many of the parts have been so proportioned that the capacity of the plant may be considerably increased at a comparatively small expense either for capital cost or yearly operating charges.

The clear water reservoir has been designed to hold 10,000,000 gallons of filtered water, which is ample to provide for very heavy fire requirements in addition to the maximum draft under ordinary conditions of use.

Main Pumping Station.—Certain work is necessary at the main pumping station on Queen Street in order to develop the best efficiency. While it is possible to use all of the present pumping equipment for some time to come, the report advises discarding some of the present pumps and substituting for them modern machines of a different type and of sufficient capacity to serve all needs with ample spare units. If this be done, the present building is sufficiently large for the installation of several new pumping units. A certain amount of work is necessary in the headrace and some remodelling of the wheelpit and tailrace is essential. Certain new drains and a proper spillway should also be constructed. The draft tube arrangements must also be modernized. Where the pure water comes into the pumping station provision should be made for a standpipe and a header or for a common suction well so that all the pumps may obtain a sufficient supply of water, which they do not get at present. On the delivery side of the pumps a common discharge header should also be installed so that any part of the distribution system of the city may receive water from any of the pumps.

Two hydro-electric units should be installed of sufficient capacity to generate current to be transmitted to the headworks pumping station and to the purification plant for the operation of the pumps at these places. There is sufficient hydraulic power available at this pumping station site for this use with a good allowance for future extensions beyond the daily average use of 25,000,000 gallons.

In the time allotted for the preparation of the report it was impossible to determine the best course to adopt in connection with the main pumping station. The above discussion is only indicative of one general programme which would be highly advantageous compared to the present state of the old plant.

The distribution system is not dealt with in the report as it has already been covered in a previous one.

Estimated Capital Costs.

1.—Intakes, cribs, two suction pipes each 54 in. x 850 ft. complete ....$	67,000
2.—Headworks pumping station, pumps and equipment, electrical apparatus and transmission lines from main pumping station..	54,000
3.—Costs of moving station and equipment to suit new elevation of Georgian Bay Canal, with new connection	25,000
4.—Two 54-in. pipe lines, as far as future pump house site with reducing and cross-connections, complete, 650 ft. each, in one trench and suitable for future suction conditions	43,000
5.—Two 42-in. pipe lines from pump house to purification plant, and thence to main pumping station, 11,300 ft. of double line in one trench, making 22,600 ft. of pipe, with valves, cross-connections and so forth, complete	356,000
6.—Real estate and right-of-way, headworks pumping station sites, reservoir and filter plant site at 10c. per sq. ft. and $10,000 for right-of-way, say	45,000
7.—Purification plant, nominal capacity 37,000,000 gallons per day, and based on average daily use of 25,000,000 gallons per day with large coagulating basins and 10,000,000-gallon clear water reservoir, complete	705,000
8.—Remodelling present pumping station, replacing units 1, 2, 3 and 4 with four 10-million-gallon turbine pump units connected to new power turbines, changes in headrace, tailrace, wheelpit and draft tubes, new suction arrangements with tank, new delivery header, two hydro-electric generating units	159,000
	$1,454,000
Add for engineering, contingencies and miscellaneous costs, say ....$	246,000
Total..........................$	1,700,000

Annual Operating Costs and Fixed Charges.—The annual operating costs and fixed charges of the system outlined include everything down to the beginning of the distribution system. The annual costs have been estimated on the same conservative basis as the capital costs. The number of men allowed for is sufficient for any contingency and will probably be less in actual practice.

The treatment necessary for the Ottawa River water requires the use of sulphate of alumina and carbonate of calcium with a final treatment with a minute quantity of sodium hypochlorite if found necessary. The amount varies from month to month, depending on the changing character of the water, but the figures given in the table below are more than sufficient to treat any condition of the Ottawa River. For protracted periods it will be unnecessary to use a final treatment. A liberal amount has been added for the item of maintenance and repairs, while oil, waste, fuel, packing, small tools and other supplies have also been provided for in the same generous degree. The charge for power should be very small. The costs of power generated in the pumping station will only be the fixed charges on the machinery equipment itself, as the labor, supplies, repairs and so forth

of the electrical equipment are included with the figures for the pumps. To provide for interest and sinking on the total capital invested, a figure of 6½ per cent. has been assumed, which should be more than ample.

Estimated Annual Operating Costs and Fixed Charges.

Wages and Salaries—	
Intake pumping station (3 operators and 3 assistant operators)	$ 5,500
Reservoir and filter plant (1 chief chemist and superintendent, 1 assistant superintendent, 3 operators, 3 assistant operators, 1 spare man)	10,000
Main pumping plant remodelled (3 assistant engineers, 3 operators, 3 assistant operators, 3 winter men, 1 spare man)	11,500
General (1 patrolman inspector, emergency help and proportion of time of waterworks engineer, say)	3,000
	$ 30,000
Supplies—	
Oil, waste, fuel, packing, small tools, and chemicals for headworks, station, purification plant and main pumping station	43,000
Repairs and Maintenance—	
Intake, pipe lines, filters and reservoirs, main pumping station, aqueduct, transmission lines, headworks pumping station and miscellaneous	16,000
Power—	
Main power service is included in operation and fixed charges	
Fixed Charges—	
Interest and sinking fund, say, 6½ per cent. on whole amount of $1,700,000...........	110,500
Total..............................	$199,500

The report concludes with the following summary: For the City of Ottawa the intake would best be placed between Remic's rapids and the Little Chaudiere Rapids. The general plan considered to be best suited consists of an overland steel pressure pipe line from the intake to a purification plant situated at the intersection of Scott Street and Parkdale Avenue. From the purification plant the pure water will collect in a service reservoir at the same site, whence it will flow in a steel gravity pipe line to the present main pumping station remodelled. The requisite power will be obtained from the present aqueduct. The system outlined above can be constructed and put in operation within two years.

The estimated capital cost of the above plant based on the average daily use of 25,000,000 gallons is $1,700,000.

The annual operating costs and fixed charges on the same basis will not exceed $200,000.

The additional annual operating costs and fixed charges which would be incurred over and above present conditions would not exceed $145,000.

After 9 years of labor the last barrier was broken on January 10th in the Catskill Aqueduct tube, the longest water tunnel in the world. It extends 111 miles, from the Ashokan dam at Esopus, N.Y., to Brooklyn; and when in operation, will supply New York with 500,000,000 gallons of water daily. The tube for the most part is 500 feet beneath the ground, and in spots dips to more than 700. It varies in diameter from 11 to 17 feet.

ONTARIO GOOD ROADS ASSOCIATION.

The twelfth annual meeting of the association was held in Toronto on February 24, 25 and 26th. Several hundred delegates, were in attendance from all parts of the province. The papers and discussions were, in the main, upon subjects bearing upon administration and financing, although a few dealt with engineering aspects of road work. Among the latter were "City and Town Streets," by A. B. Macallum, City Engineer, Hamilton; "Bridge Construction," by L. E. Allen, Belleville, Engineer, Hastings County, and others. C. A. Macgrath, Ottawa, chairman, Ontario Highway Commission, gave an address during one of the sessions on the work of the Commission.

MODERN CONCRETE CONSTRUCTION.

Some very interesting concrete work has just been completed by the American Cyanamid Company of Niagara Falls, Ont. The construction was started last October of a Silo Building, 90 feet high, having 184 corners to its 16 columns. The columns are connected by 16 very large triangular lintels, which are heavily reinforced. They support nine 18 x 18 feet bins, 50 feet high, each have a suspended concrete hopper.

These bins carry a weight of ten thousand tons of cyanamid. The entire building, from foundation to roof, was built with the Blayney system of steel forms, manufactured by the Standardized Steel Form Company, Niagara Falls, Ont. With a slight change, the column forms were used as wall forms right to the roof.

1914 WORK IN MEDICINE HAT.

The following work is contemplated for the coming season in Medicine Hat, Alta.:—

Surface and stearm sewers	$ 60,000
Extending and improving waterworks	175,000
Parks and other municipal purposes	14,000
Extending and improving electric plant, light system and power system	150,000
Extending gas system and drilling gas wells	50,000
Grading and gravelling streets and purchase of road construction plant and machinery.........	50,000

A paper was presented by G. E. Lygo before the Junior Institution of Engineers in England, showing that plants in which all kinds of wood waste, from sawdust to pieces 6 inches in diameter, as well as cotton seeds, cocoanut shells, coffee husks and many other kinds of refuse, can be used for the manufacture of producer gas are now being manufactured in England. In designing a plant for this purpose many changes must be made from the coal producer. The surface area required is determined by the nature of the fuel used and its size, but will average 2.5 times that required with coal. The depth of the fuel bed will depend upon the size and density of the fuel. A deep bed is necessary where the pieces are large; whereas a shallow bed is preferable with small fuel like sawdust. A vaporizer is not required. The gas must be cooled and washed immediately upon leaving the generator or else the heavy tar in suspension is deposited and will choke the piping. The calorific value of wood when air-dried is approximately 6,000 British thermal units per pound. The amount consumed in generating a horsepower-hour depends upon the moisture, which varies from 10 to 20 per cent. in air-dried wood to 30 or 50 per cent. in fresh wood. Fuel containing an excess of moisture must be dried until it is reduced at least to 60 per cent.

MONTREAL WATER SUPPLY CONDUIT

REPORT OF THE BOARD OF EXAMINERS OUTLINING DEVELOPMENT OF CITY'S WATER SUPPLY AQUEDUCT, CONDITION OF THE CONCRETE CONDUIT, GENERAL CONCLUSIONS AND RECOMMENDATIONS.

THE following is from the report to the Board of Commissioners of the City of Montreal covering the result of the investigation of Messrs. J. A. Jamieson, R. S. Lea, and G. R. Heckle, Board of Engineers, as to the cause of the accident to the city waterworks conduit*; the measures necessary to provide, as far as possible, against any further damage; and the condition of the entire conduit as shown by inspection of its interior, and the exterior condition of the aqueduct bank adjacent to and overlying it:—

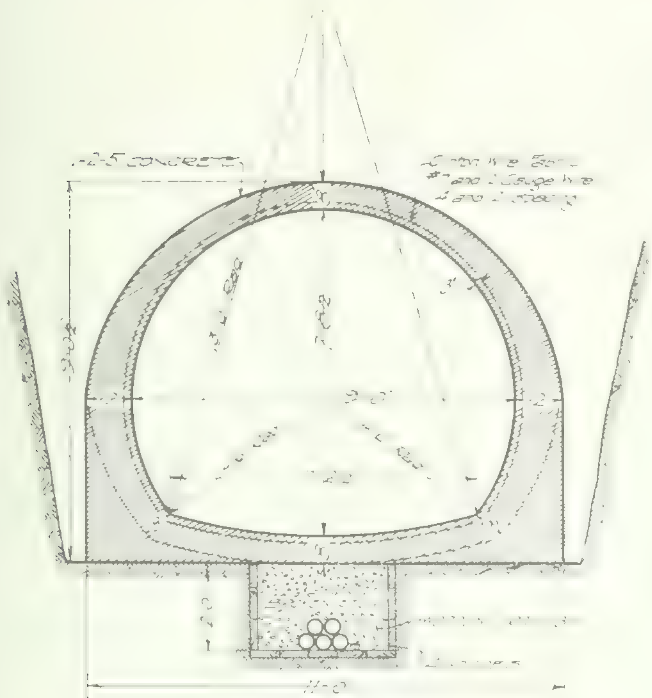

Fig. 1.—Cross-Section of the Conduit.

Description of the Water Supply System.—As the question of the conduit is intimately associated with the enlargement of the aqueduct, a brief history of the more important events in connection with the city's water supply is necessary to give a more complete understanding of the subject.

*See *The Canadian Engineer*, January 8th, 1914, Page 151.

The City of Montreal has, for many years, obtained its water supply from the St. Lawrence River through an open canal, or aqueduct, as it is locally known, extending from a point some distance above the Lachine Rapids, and running in a northeasterly direction nearly parallel to, but a considerable distance from, the river to the pumping station located at the junction of Centre Street and Atwater Avenue.

For a number of years following its construction, this aqueduct supplied water for city consumption, and also furnished hydraulic power for pumping the water into the city mains and reservoirs. As the population and water consumption increased, the hydraulic power became inadequate, and a supplementary steam pumping plant was installed. Eventually the hydraulic power available from the aqueduct represented such a small proportion of the total requirements for pumping purposes as to be almost negligible.

The question of enlarging the aqueduct to a size sufficient to supply power for pumping the total quantity of water required for city consumption had been investigated and reported upon by various engineers from time to time, and in 1907, based on a report submitted by Mr. Geo. Janin, Chief Engineer of Public Works of the City of Montreal, it was decided by the authorities to proceed with the enlargement referred to above.

The conduit which failed on December 25th, 1913, was built to protect the city water supply against surface pollution between the river and the pumping station, and also to provide continuous service while the aqueduct was being enlarged, during which period it constituted the only source of supply.

This conduit extends from the St. Lawrence River to the pumping station, and is located in a trench along the north bank of the aqueduct. The water flows through it by gravity under a head varying from six to twelve feet. It is constructed of concrete lightly reinforced with Clinton wire fabric. The plans and specifications were prepared under the direction of Mr. Janin. Fig. 1 shows the cross-sectional plan. The contract for its construction was awarded to Mr. P. McGovern, under date of October 3rd, 1907, and the work was completed about two years later.

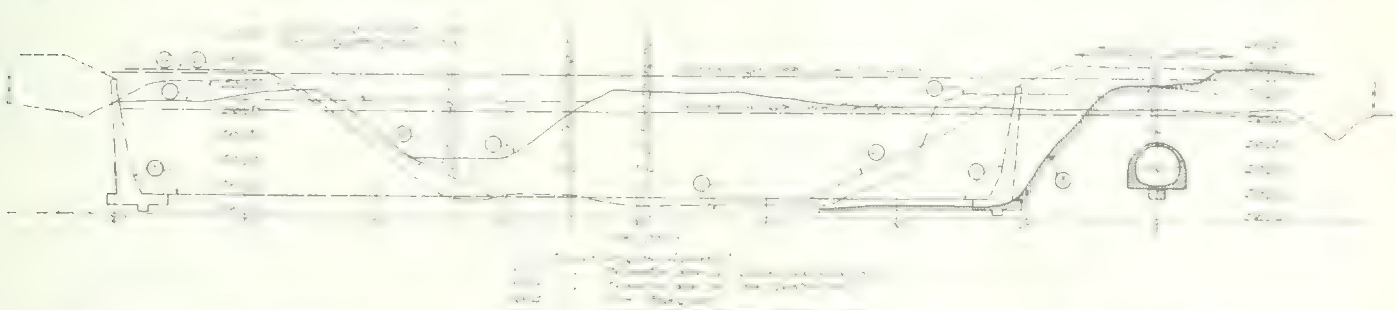

Fig. 2.—Section Showing Relative Size of Old Aqueduct, Enlargements 1 and 2, and Location of the Conduit.

On October 12th, 1909, a contract for the enlargement of the aqueduct was awarded to Messrs. Quinlan and Robertson. This is now known as Enlargement 1. The enlarged section was estimated to carry sufficient water to produce 2,500 h.p. during the winter months, with a probable 5,000 h.p. during the summer, to be used for pumping the city's water supply.

Before the work covered by the above contract was entirely completed, it was decided by the city authorities to still further enlarge the aqueduct in order to obtain sufficient power to generate electric current for lighting purposes in addition to pumping the city water. This is now known as Enlargement 2, for which the plans and specifications were also prepared under the direction of Mr. Janin. Fig. 2 shows the relative size of the old aqueduct, enlargements 1 and 2, and the location of the conduit.

To obtain the necessary cross-sectional area of aqueduct, and, at the same time, to keep as nearly as possible within the limits of the property owned by the city, the plans for Enlargement 2 required the excavation to be carried much closer to the conduit than under contract 1.

The contract for Enlargement 2 was awarded by the city to the Cook Construction Company, under date of July 17th, 1913. This company, in carrying out the work under their contract, employed drag-line excavators for the earth excavation. These machines, which weigh 120 tons each, operate from the top of the banks, moving along on skids and rollers, and perform their work by swinging 3-cu.-yd. drag-buckets into the excavation by means of cables and boom. This drag-line bucket is then drawn towards the machine by a cable and digs into the earth as it is hauled up the slope, depositing the excavated material on the bank. The location and operation of this heavy machine (See Fig. 3) over the conduit imposed a heavy live load on it concurrently with the removal of its lateral support on the aqueduct side. The effect of this was to cause a readjustment and sliding of the bank which tended to produce excessive stresses in the conduit.

During December, one of these machines was working eastwards along the north bank over the conduit, and between Sta. 119 and 129 the excavation was carried so close to the conduit that an earth slide partially exposed its side between Sta. 123 and 124, about 100 ft. east of the Asylum bridge. Inspection showed that considerable water was leaking from the conduit at this point through cracks in its side, and attempts were made to stop the leaks and support the conduit, but without success. At about 4.30 p.m. December 25th, the side of the conduit burst out for a length of about 60 feet, as shown in Fig. 3.

As this break in the conduit entirely cut off the city's water supply, emergency repairs were planned by Messrs. Janin and Lesage, and the Cook Construction Company's plant and organization were called upon to execute the work. These repairs were made and the water again let into the conduit on January 2nd. Since then the supply has not been interrupted.

Fig. 3.—Montreal Waterworks Conduit Break as it Appeared on December 27th, 1913. (Drag line excavator has been moved up from point of operation at extreme right of photo, to be used in excavating the earth around the break).

Examination of the Conduit.—On December 28th, Mr. J. A. Jamieson was retained as consulting engineer, and during the following 48 hours made an inspection of the interior of the conduit, accompanied by Messrs. Janin and Lesage. On December 30th, Messrs. R. S. Lea and G. R. Heckle were retained, on which date they, accompanied by Messrs. McKillop and Ommaney, Canadian Pacific Railway engineers, inspected the interior of the conduit.

The condition of the conduit as disclosed by this inspection was as follows:—

The concrete was found to be of good quality and workmanship throughout the entire length. The conduit from the intake end at river, Sta. 270 + 50 to Sta. 220, was found to be practically free from cracks or other defects. Along this part of the conduit the depth of the overlying earth is only 6 to 8 ft.

At about Sta. 220, there is a coffer-dam built across the aqueduct. From this point to the river the water stands in the aqueduct at the river level, while from the cofferdam eastward to the pumping station, the aqueduct has been unwatered to permit the enlargement to proceed.

Between Sta. 220 and 214, a distance of 600 ft., a serious crack was found in the crown of the arch. This crack was about ⅜-in. in width, and in places the roof on one side has sunk down about ⅜-in. further than on the other. There are also corresponding cracks in the invert, and signs of strain along the springing line on both sides. These cracks clearly indicate a distortion of the conduit from an overlying load.

An inspection of the interior disclosed the fact that along the cracked section excavated material had been dumped directly over the conduit up to about El. 58, making the overload about 25 ft. above the crown, plainly accounting for the cracked and distorted conditions found. The east end of the cracked section corresponds with the point where the conduit passes from earth into rock.

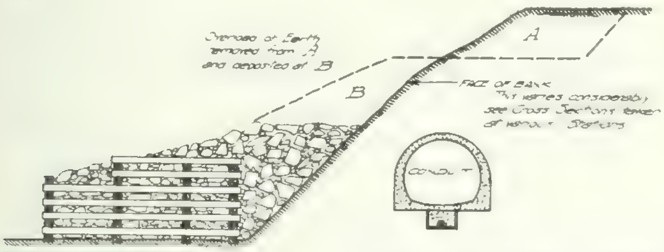

Fig. 4.—Method Adopted to Support Bank and Conduit.

A subsequent inspection along the aqueduct bank showed a very considerable leakage of water from the conduit along the cracked section between Sta. 220 and 214. For the most part, this water finds its way into the aqueduct through gravel strata, and shows no signs of transporting any of the clay material; and the conduit is located at this point approximately 40 ft. back from the aqueduct bank.

Between Sta. 214 and 133, the conduit is located partially or wholly in rock, and was found to be generally in good condition.

Between Sta. 133 and 120, there are cracks along the crown, both sides, at about the springing line of the arch, and in the bottom, but as a rule these are not open to any extent. They indicate considerable stress, however, and some distortion in the conduit. It is in this section, between Sta. 123 and 124, that the break occurred, and an inspection made after the conduit was filled with water disclosed the fact that, at several points along the bank, water was leaking from the conduit and finding its way into the aqueduct.

Between Sta. 69 and 120, there is a light crack along the crown for a considerable part of the distance, but for the most part this crack is comparatively small. An apparent leak has been found in this section near Sta. 94, but the water was running out through gravel strata and was quite clear, indicating that the leakage is probably not endangering the conduit at this point.

Between Sta. 69 and 50, the conduit is cracked along the crown and in the invert, these cracks being open for the most part about ⅛ in., and by cutting into the concrete at certain points it was found that the reinforcing wires were broken in the crown. There are also some cracks at about the springing line of the arch. Along this section it was found that the original fill over the conduit was only 5 ft., but that during the operations under the Quinlan and Robertson contract, excavated material from the aqueduct had been deposited along the bank over the conduit up to approximately El. 45, making the fill about 15 ft. higher than the top of the conduit. This fill, however, is not generally over the centre of the conduit, but south of it, thus producing an unbalanced load. A close examination would indicate that these cracks were not of recent date.

Between Sta. 50 and about 30, the conduit was in good condition, showing no evidence of anything beyond occasional fine cracks. It was impossible to proceed further east with the inspection on account of the depth of water.

An inspection was made of the existing head gates at the entrance of the aqueduct, and where the section has not been disturbed by either Contracts 1 or 2. It was found that the aqueduct had been provided with both head gates at the entrance from the river and regulating gates further down, but that in both cases the gates were in very bad repair, and entirely useless at the present time.

As there should be a means available at all times for controlling the flow of water in the aqueduct, it is urged that the Cook Construction Company proceed at once with the construction of the coffer-dam at the entrance as covered by their contract, also that the necessary gates and sluices for controlling the flow be included in the structure.

Recommendations After First Inspection.—On the night of December 30th, after completing the above inspection of the interior of the conduit, the Board of Engineers met Controller Godfrey, Messrs. Janin and Lesage, and Mr. Herlihy, of the Cook Construction Company, at the city's office near the break, and verbally made certain recommendations, as follows:

1. That rip-rap be placed against the toe of the slope along the weakened sections in the vicinity of the break as rapidly as possible.

2. That, when the water was turned into the conduit, it should not be allowed to run more than ¾ full, and kept below that depth if possible.

3. That the overload of earth be removed from the top of the conduit for a considerable distance east and west of the break.

4. That the overload on the section lying approximately between Sta. 214 and 220 be also removed as soon as possible.

5. That the excavation work on the north side of the aqueduct be suspended, and that for the present no blasting be allowed in the rock section on the north side.

These verbal recommendations were confirmed and further emphasized in a written report addressed to the Board of Commissioners under date of January 7th, in which certain other additional recommendations were made, including the construction of a rock-filled timber crib along the toe of the bank at the weakened section both east and west of the break, to support a fill in an endeavor to reproduce the original conditions of loading.

In accordance with the recommendations of the interim report, an arrangement was made by the Board with the Cook Construction Company to proceed immediately with the carrying out of the work involved. The most important measure, namely, placing rip-rap along the toe of the slope at the weakened section on both sides of the break, between Sta. 119 and 129, to be followed at once with the construction of a rock-filled crib, was proceeded with first, night and day shifts being employed. Mr. J. R. Dorrance was placed in charge of the work by the city, as resident engineer, and Mr. F. S.

Pearson, as superintendent. While the above-mentioned work was being carried out, the very difficult matter of securing the conduit at both ends of the steel pipe at the break was being done. This work required the utmost care as it was found that cavities had been eroded on both sides of the conduit and directly underneath by leakage, which, of course, made the situation a very serious one. Blocks of concrete were placed in sections underneath the conduit where the foundation was scoured out, and the leaks in the side were caulked and afterwards encased in concrete. The water draining through the conduit in both directions towards the break and at other points on both sides was carried in troughs to the aqueduct, so that no further scouring would occur.

Fig. 4 shows a cross-section through the rock-filled crib, and the conduit, and gives a general idea of this work.

When the protection work adjacent to the break was well under way, a force was started removing the excessive load from the top of the conduit between Sta. 214 and 220, a wedge-shaped section being taken off to El. 47, approximately, thus removing about half the load over the crown. It was considered advisable to do this work entirely by hand labor, on account of the danger of using machinery adjacent to this cracked section.

At this time it was thought advisable by the Board, and with the approval of Mr. John R. Freeman, to lay a pipe connecting the Lachine canal with the present pump-well; this work being at once proceeded with. This precaution was justified by the possibility of another break in the conduit which might expose the city to the danger of a conflagration. It should not interfere in any way, however, with measures being taken as soon as possible for furnishing the city with an alternative supply of pure water, and that water from the Lachine canal should not be turned into the city mains except as a last resport.

Details of Design and Construction of Conduit.—Fig. 1 shows a cross-section of the conduit used in soft soil. The dotted line below the springing line of the arch shows the form used in firm soil or rock. In both the latter cases, the reinforcement was to be omitted below a point 12 in. below the springing line. In firm soil, the earth was to be excavated to the neat line of the bottom and the side walls. In rock, any excess excavation was to be filled with lean concrete composed of 1, cement; 3, sand; 8, 3-in. broken stone.

Article 18 of the specifications covers the character and location of the reinforcement. It reads as follows:

> The reinforcing material of the conduit shall consist of expanded steel No. 6 with 6-in. mesh; or of other reinforcing metal which shall be known to have an equal degree of resistance. In the case of tenderers wishing to substitute a different material than No. 6 expanded steel with 6-in. mesh, they will have to clearly specify the nature and weight of the reinforcing material they propose to make use of. The reinforcing metal shall be set at about 3 in. from the interior surface of the conduit, and each sheet of metal shall be lapped over the adjoining one, to the width of one mesh to form a continuity of joints, but only in the crown of the conduit shall the adjoining sheets of metal be attached together with wire.

As will be noted in Fig. 1, Clinton wire cloth was substituted for the expanded metal specified.

With regard to the design of the conduit. From the information which we have obtained from the city, the maximum depth of fill over the crown would be approximately 25 ft. Engineering practice in concrete conduit design exhibits a considerable variation in the sections of concrete and the percentage of reinforcement used. While there are examples of as light, or possibly lighter, types of similar structures in existence, we consider the concrete sections employed in the Montreal conduit are lighter than are warranted by safe engineering practice. We feel, moreover, that the percentage of steel used and the position in which it is placed does not constitute an adequate reinforcement against the stresses to which the structure is subjected. The above statements are particularly pertinent having regard to the fact that this conduit represented the only water supply line to the city.

The weight per sq. ft. of the reinforcement called for in the specifications is not stated therein, and as expanded steel of this particular class is not now commonly manufactured, we have not been able to definitely compare the relative weights of the steel fabric specified with that actually used. So far as our information goes, however, it appears to us that the reinforcement does not represent an adequate equivalent for the expanded steel referred to in Art. 18.

So far as our inspection of the conduit enables us to report on the matter, we consider that the concrete is of good quality and that in general the work has been well executed.

The soil through which the aqueduct is being excavated and in which the conduit is embedded for the greater part of its length, is largely composed of boulder clay or rock powder. When comparatively dry, or well drained, it will stand in a bank with practically vertical face, but when fully saturated with water tends to flow a horizontal surface, and is easily eroded and transported by running water. This latter property has a very direct bearing on the safety of the conduit, in view of the proximity of the aqueduct excavation.

Water leaking from the conduit under pressure tends to find an outlet through the intervening bank into the adjacent aqueduct, the bottom of which is about 5 ft. lower than the invert. This water erodes and transports the soil surrounding the conduit, removing its lateral support, and the leaks are a serious source of danger, so long as the aqueduct remains unwatered.

The only practical way to stop these leaks, in the opinion of the Board, is by filling the cracks from the interior. This, however, can only be done by unwatering the conduit. Under existing conditions, however, this latter cannot be done within a reasonable time owing to the fact that there is only one 12-in. pipe through which the conduit can be drained. The suction pipes of the pumps at the pumping station do not extend sufficiently low by several feet to permit the conduit being unwatered by pumping. We would, therefore, recommend that the installation of a new suction well or gallery, at least 6 ft. lower than the existing one, should be immediately constructed, and the suction correspondingly lowered. This arrangement would permit the conduit to be quickly unwatered, and the work of interior repairs proceeded with during short periods, and would also permit the conduit being run partially full of water.

Work on the Aqueduct.—Referring to the contract of the Cook Construction Company for the widening and deepening of the aqueduct, it is found that the contractor is required to construct reinforced concrete retaining walls along both sides of the aqueduct in the earth section, and plain concrete retaining walls in the rock section.

While the contractor is, in his contract, called upon to use extreme care and diligence in his work in order

not to endanger in any way the water supply conduit, and is particularly cautioned regarding the sections between Stations 10 and 14, and from 80 to 85, it is not found that there is any particular provision made by which the contractor is obliged to follow up his earth excavation immediately with the construction of the retaining walls. Moreover, the contract provides that the contractor construct test sections of the wall when ordered by the engineer and before proceeding with the general construction. This would seem to indicate that the city engineers did not expect the contractor to follow up his earth excavation very closely with the retaining walls. It also seems to indicate that the city engineers themselves were not quite satisfied that the wall as designed was sufficiently strong for the purpose intended.

It is obvious from what has already occurred and from the present condition of the north bank in the earth section, that unless the wall construction followed the excavation very closely, the conduit would be greatly endangered, as there are points east of where the break occurred where the plans show that the excavation was to be carried much closer to the conduit than at points already excavated.

As one of the recommendations, made immediately after the first inspection of the conduit by the Board and confirmed by its interim report, was to the effect that all work on the north side of the aqueduct should be suspended by the contractor for the time being, we have felt obliged, in preparing this report, to make an analysis of the design of the reinforced concrete retaining wall which the Cook contract provides shall be built in the earth section. From this analysis we have found that the wall would not be stable for the loads which we believe it prudent to assume it would have to sustain.

Another apparent weakness in this design is that the bottom of the concrete base is only 1 ft. 9 in. below the bottom of the canal. If the structure were left exposed during construction in the winter time, or if, at a later period, the canal should be emptied of water in the winter time, there would, we believe, be great danger of frost penetrating under the base, causing serious damage to the wall.

Conclusions.—From a review of the features which have been described in this report, we have arrived at the following conclusions:—

1. That the plans and specifications of the conduit did not call for sufficient reinforcement, nor is the steel properly placed in the concrete section, to provide a sufficient factor of safety, especially in view of the fact that the conduit would be the only means of supplying the city with water during the enlargement of the aqueduct.

2. That in the construction of the conduit the quality of the concrete and the workmanship generally were good, but that the weight and strength of the steel reinforcement was much less than called for by the specifications submitted to us.

3. That the insecurity of the conduit was greatly increased by the proximity of the excavation involved in carrying out Enlargement No. 2.

4. That the method of performing the work by means of a heavy drag-line excavator travelling on top of the bank above the conduit imposing a heavy vibrating load concurrently with the removal of the earth which provided lateral support to the conduit further endangered the structure.

5. That the leakage of water from the conduit is an additional source of danger at points where the conduit is located in easily eroded soil, and the excavation carried sufficiently close to permit the water finding an outlet into the aqueduct.

6. That the failure of the conduit was due to the proximity of the excavation, to the methods employed in the execution of the work, and to the inherent weakness of the conduit itself.

7. That the conduit, as a permanent means of supplying water to the city, is not now to be depended upon.

8. That it would be unsafe to proceed with any further excavation in the earth section on the north side of the aqueduct with the conduit in its present condition and while there is no other water supply available.

9. That is is unsafe to do any blasting in the rock section on the north side of the aqueduct.

10. That it is unsafe to allow the travelling excavators or locomotives or any other similar heavy machinery to be operated on or moved at any point over the top of the conduit.

11. That the reinforced concrete retaining wall as designed by the city and to be built by the Cook Construction Company along the banks of the aqueduct in the earth section is not, as designed, a safe structure to build for the purposes intended.

12. That a revision of the design of this wall, in order to make it safe, will greatly increase the cost of the project.

With the above facts as a basis, we beg to make the following recommendations:—

1. That before any further work is proceeded with, at least on the north side of the aqueduct, an investigation be made by a commission of engineers into the entire aqueduct scheme, which will include revised estimates of the cost of construction, and the quantity and cost of the power developed.

2. That the city at the earliest date possible make arrangements for providing a new and independent water supply of a suitable character, so located that it cannot be affected by any further accident which might happen to the present conduit.

3. That a permanent coffer-dam or intake be at once constructed at the entrance to the aqueduct including proper gates or sluices that may be required, so that the flow of water into the aqueduct may be at all times under control.

4. That until another suitable water supply has been provided, the present one should be kept continuously under observation so that in case the present leaks become serious prompt remedial measures may be taken.

5. That the suction pipes of the pumps at the pumping station be lowered by at least six feet as soon as possible so that the conduit may be run partly full or may be quickly emptied.

Respectfully submitted,

(Signed) J. A. JAMIESON,
R. S. LEA,
G. R. HECKLE.

[A detailed description of the emergency repairs to the break and the subsequent repair work is to follow as an appendix to the report.—Editor.]

A proposition, recently announced, which will ease considerably the meagre traffic facilities of Iceland, is a million-dollar railroad to be started in Iceland at an early date, extending from the capital, Reykjavik, in an easterly direction across the plain of Thingvala, a distance of about 58 miles, to the Olfusa Bridge. Ultimately it is proposed to extend this line to Thorsjaa, where the line will branch off in two directions, one going to the geysers and the other to Cerbak.

Coast to Coast

Bassano, Alta.—It is stated that the C.P.R.'s $9,000,000 dam will be completed at Bassano early in the spring, and water will be turned into the vast network of trenches.

Fort William, Ont.—The amended plans for the new C.N.R. station at Fort William show a brick and stone building, 143 by 24 feet; and the cost of the structure is estimated at $38,000.

Port Nelson, Ont.—Wireless signals from the new station at Port Nelson have been received at Le Pas, some 450 miles distant, showing that the plant of the new Hudson Bay terminal is now installed.

Windsor, Ont.—The towers of the Niagara power transmission line have reached Chatham, and all the tower foundations are constructed to Windsor, so that it is believed that by June, power will be in use in the latter city.

Fort William, Ont.—It is expected that this week will see the end of construction on the Stanley Avenue sewer at Fort William. The cost will be about $35,000 more than the original estimate of $54,000, due to an additional length of 600 feet added to the sewer since the contract was let, and also to the peculiar soil conditions which were encountered along the route of the sewer.

Montreal, Que.—At a recent meeting of the Montreal Chambre de Commerce, Mr. P. E. Lamarche, member for Nicolet, spoke in favor of the construction of the Georgian Bay canal, referring to the water power that might be developed from the project and which might earn enough to pay the interest and some of the sinking fund on the $150,000,000 which would be required to construct it. He also argued in reply to those who say the work will cost too much that it will justify itself just as the railways have done; that it will foster interprovincial trade, and besides forming a passage-way for the wheat, will enable coal to be sent to the West from Nova Scotia.

Toronto, Ont.—At the meeting of the Associated Boards of Trade on February 25 at Toronto, Mr. J. F. Black, Sudbury, advocated that the Hydro-Electric Commission be asked to proceed with the development of power in New Ontario, and that the Federal and Provincial Governments arrange to adopt this policy at an early date. A proposal to reforest waste lands that are useless for farming was approved by the board, and a resolution of five boards—Fort William, Port Arthur, Soo, Steelton, North Bay and Sudbury—was adopted, favoring Government assistance in mining and treatment of Canadian iron ore, such as will keep this trade in the Dominion, to be developed for the benefit of the Canadian people.

Montreal, Que.—The improvements to the harbor and terminal facilities at Montreal, contemplated by the Harbor Commissioners of Montreal to be carried out during the next 4 years, will call for an expenditure of $15,000,000. This year $3,500,000 will be utilized in developing the port, whereas last year $2,600,000 was consumed in this work. The exact programme for this year has not yet been decided, though it is believed that it will include the construction of two new freight and transportation sheds to accommodate the Hamburg-American and Canadian Northern weekly services; the electrification of the entire system of harbor railways; the elevation of the railway tracks between McGill Street and Victoria Pier; and the erection of a new mammoth warehouse at the foot of Morau Street and another at the foot of Beaudry Street. Plans adopted by the board call also for the extension of several piers, the erection of a new St. Lawrence bridge and the building of a new grain elevator, so as to give Montreal the largest storage capacity in the world.

Medicine Hat, Alta.—Contracts have been awarded by the city council of Medicine Hat for $65,000 worth of machinery and equipment at the new municipal power station, which will bring the total cost of that utility to approximately $500,000, including the modern and up-to-date pumping, generating and filtration system. Originally the new station was equipped with 2,400 h.p. gas-fired boilers, two 750 k.w. turbine alternators, and four 1,000,000-gallon filter beds, with the requisite high and low-lift pumping equipment. When the new machinery is installed and in running order later in the year, the station will be capable of generating about 4,000 h.p., and the filtration plant will handle 9,000,000 gallons of water each 24 hours. While the new power station has only been in commission two or three months, the steady and substantial industrial and municipal expansion has been such that additional machinery and equipment were essential, in order that the plant should not be seriously strained or rendered less effective by overloading in the immediate future.

Vancouver, B.C.—Mr. Frank Bowser, chairman of the Burrard Peninsula Joint Sewers Commission, has stated that approximately $2,000,000 will be expended in sewers for Greater Vancouver this year. Of this amount the approximate outlays will be $1,000,000 in Vancouver, $750,000 in South Vancouver, $100,000 in Point Grey, and $100,000 in Burnaby. In Vancouver the expenditures will include the purchase by the commission of the Balaclava Street, the Bridge Street and the China Street trunk sewers, at a cost of about $300,000. The work on the extension of the China Creek trunk will claim the expenditure of about $250,000, and the Clarke Drive outfall will entail an expenditure of something like $325,000. The Balaclava Street trunk sewer will be carried on from Ninth Avenue to the city boundary at Sixteenth Avenue, and a branch will be laid, probably along Tenth Avenue, as far east as the base of Shaughnessy Heights, to serve the territory in the declivity between the Kitsilano Hill and the Heights. In the extension of the main trunk sewer out to Central Park, this year's expenditures include work to cost something over $350,000, while another $200,000 will be paid for branches connecting with this work, all in South Vancouver. In Point Grey the commission will take over the Key Road sewer from the municipality at a cost of about $50,000, as well as undertake new work.

Sarnia, Ont.—As has been announced, plans are under consideration for an electric railway from a point in or near the town of Sarnia, down the scenic route along the bank of the St. Clair River through Corunna, Mooretown, Courtright, Sombra and Port Lambton, hence to Wallaceburg, where it will connect with MacKenzie and Mann's Wallaceburg, Chatham and Lake Erie Railway. From the village of Corunna a branch line will be constructed into Petrolea and probably further. The company contemplates the purchase of a charter already extant, which would give it power to construct the line of standard gauge railway; to acquire, charter and dispose of steam and other vessels, etc.; to construct, acquire and lease wharves, docks, elevators, warehouses, etc.; to operate a ferry line between Sarnia and Port Huron, and between Corunna, Stag Island and Marysville, Mich.; to operate a line of steamers from Sarnia down the St. Clair River; to erect and operate telephone and telegraph lines; and also to generate, transmit and sell power to the municipalities through which the line will pass. It is estimated that including all equipment, the construction of the line will cost about $1,000,000.

NEWS OF THE ENGINEERING SOCIETIES

Brief items relating to the activities of associations for men in engineering and closely allied practice.
THE CANADIAN ENGINEER publishes, on page 90, a directory of such societies and their chief officials.

OTTAWA BRANCH—CAN. SOC. C.E.

On February 5th, Mr. C. P. Edwards, general superintendent of Government Radio-telegraphs, Department of Naval Service, gave an illustrated address to the Ottawa members of the Canadian Society of Civil Engineers. About 350 were in attendance at the meeting, which was held in the Normal School hall. The lecture was accompanied by some practical demonstration by means of apparatus set up for the purpose.

Mr. J. W. W. Drysdale, of Glasgow, Scotland, read a paper before the branch on February 12th. His subject was Centrifugal Pumping Machinery* and brought out some interesting discussion.

The February 19th meeting took the form of a luncheon at the Russell Hotel. About 50 were in attendance. Mr. G. A. Mountain, chairman of the Branch, presided.

Some very promising papers have been arranged for presentation during the balance of the season. The "New Welland Ship Canal" will be described by Mr. J. L. Weller, of St. Catharines, chief engineer of the project, on the evening of March 5th. The paper will deal with the location, the history, and the most interesting engineering features of the canal, and will be illustrated with lantern views. Mr. E. S. Mattice, of Montreal, will lecture at a later date on "Steel Building Construction"; and Mr. Walter J. Francis, of Montreal, will give an address on Engineering Ethics.

*See *The Canadian Engineer*, February 12th, 1914.

CANADIAN MINING INSTITUTE.

The seventeenth annual meeting of the western branch of the Canadian Mining Institute was held in Vancouver, on February 20th. Delegates were present from all parts of the province, and several instructive papers and discussions on mining matters particularly affecting the province of British Columbia were heard.

INSTITUTE OF MINING ENGINEERS.

Before the American Institute of Mining Engineers in New York on Friday, February 20, Eugene Coste, M.E., geologist and mining engineer, of Calgary, read a paper dealing somewhat exhaustively with certain phases of oil and gas strata under the general title "Rock Disturbances Theory of Petroleum Emanations vs. the Anticlinal or Structural Theory of Petroleum Accumulations."

AMERICAN SOCIETY FOR TESTING MATERIALS.

The executive committee of the American Society for Testing Materials has announced that the seventeenth annual meeting will be held at Atlantic City, N.J., June 30 to July 4, 1914, with headquarters at the Hotel Traymore. As it is desired that papers and committee reports be printed and circulated in advance of the meeting, all manuscripts should be in the hands of the secretary-treasurer by April 15.

COMING MEETINGS.

AMERICAN WATERWORKS ASSOCIATION.—Thirty-fourth Annual Meeting to be held in Philadelphia, Pa., May 11-15, 1914. Secretary, J. M. Deven, 47 Slate Street, Troy, N.Y.

CANADIAN AND INTERNATIONAL GOOD ROADS CONGRESS.—To be held in Montreal, May 18th to 23rd, 1914. Mr. G. A. McNamee, 909 New Birks Building, Montreal, General Secretary.

AMERICAN SOCIETY FOR TESTING MATERIALS.—Seventeenth Annual Meeting to be held in Atlantic City, N.J., June 30 to July 4, 1914. Edgar Marburg, Secretary-Treasurer, University of Pennsylvania, Philadelphia, Pa.

PERSONALS.

J. CHALMERS, Commissioner of Public Works, Edmonton, is on a trip through Eastern Canada.

CYRIL G. SAVAGE was appointed secretary-treasurer of the Canadian British Insulated Co., Limited, Montreal, at a recent directors' meeting. Mr. Savage succeeds HAROLD BROWN, resigned.

E. BRYDONE-JACK, Winnipeg; H. J. DUFFIELD, Calgary; and A. BROOM, Montreal, are reported to have been recently elected to membership in the Institution of Civil Engineers of Great Britain.

W. J. WALKER, A.M.I.E.E., is delivering a series of eight weekly lectures to the members of the Electrical Society of Vancouver, dealing with the construction and maintenance of storage batteries and their practical application.

W. T. WOODROOFE, for the past 1½ years superintendent of the Edmonton Street Railway, has recently sent in his resignation, to take effect April 1st. Mr. Woodroofe was previously with the British Columbia Electric Railway Company.

FRANK DITCHFIELD, formerly general superintendent of the Canadian Car and Foundry Co., Limited, has joined the staff of the Mechanical Engineering Co., Limited, of Montreal, and will direct the affairs of the company's consulting engineering department.

ARTHUR H. BLANCHARD, M.Am.Soc.C.E., Professor in Charge of the Graduate Course in Highway Engineering at Columbia University, on February 19, 1914, delivered illustrated lectures at the Ohio State University on the subjects:—"Road Legislation, Present and Future," "Bituminous Surfaces and Bituminous Pavements" and "Foreign Highways."

OBITUARY.

JOHN O. BROWN, civil engineer and railway builder, died at Fredericton, N.B., on February 25th, at the age of 71. During his career he had been identified with the construction of several of the important lines in Canada and the United States. He built, owned, operated and finally sold out the Northern Railway, and was interested in the building of what is now a part of the Northern Division of the C.P.R. in Madawaska County, and also the Central Railway.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.
